898-99

U. S. DEPARTMENT OF AGRICULTURE

Scientific Bureaus and Divisions.

- WEATHER BUREAU—Willis L. Moore, *Chief*.
 BUREAU OF ANIMAL INDUSTRY—D. E. Salmon, *Chief*.
 DIVISION OF STATISTICS—J. Hyde, *Statistician*.
 DIVISION OF ENTOMOLOGY—L. O. Howard, *Entomologist*.
 DIVISION OF CHEMISTRY—H. W. Wiley, *Chemist*.
 DIVISION OF BOTANY—F. V. Coville, *Botanist*.
 DIVISION OF FORESTRY—G. Pinchot, *Chief*.
 DIVISION OF BIOLOGICAL SURVEY—C. Hart Merriam, *Biologist*.
 DIVISION OF POMOLOGY—G. B. Brackett, *Pomologist*.
 DIVISION OF VEGETABLE PHYSIOLOGY AND PATHOLOGY—B. T. Galloway, *Chief*.
 DIVISION OF SOILS—M. Whitney, *Chief*.
 DIVISION OF AGROSTOLOGY—F. Lamson-Scribner, *Agrostologist*.

OFFICE OF EXPERIMENT STATIONS—A. C. True, *Director*.

THE AGRICULTURAL EXPERIMENT STATIONS.

- ALABAMA—*Auburn*: College Station; P. H. Mell. *Montgomery*: Cambridge Station; W. Collins.†
- ARIZONA—*Tucson*: R. H. Forbes.
- ARKANSAS—*Fayetteville*: R. L. Bennett.*
- CALIFORNIA—*Berkeley*: E. W. Hilgard.
- COLORADO—*Fort Collins*: L. G. Carpenter.*
- CONNECTICUT—*New Haven*: State Station; S. W. Johnson.* *Storrs*: Storrs Station; W. O. Atwater.*
- DELAWARE—*Newark*: A. T. Neale.*
- FLORIDA—*Lake City*: W. F. Vocum.*
- GEORGIA—*Experiment*: R. J. Redding.*
- IDAHO—*Moscow*: J. P. Blanton.*
- ILLINOIS—*Urbana*: E. Davenport.*
- INDIANA—*Lafayette*: C. S. Plumb.*
- IOWA—*Ames*: C. F. Curtiss.*
- KANSAS—*Manhattan*: J. T. Willard.‡
- KENTUCKY—*Lexington*: M. A. Scovell.*
- LOUISIANA—*Audubon Park, New Orleans*: Sugar Station. *Baton Rouge*: State Station. *Cathouin*: North Louisiana Station.; W. C. Stubbs.*
- MAINE—*Orono*: C. D. Woods.*
- MARYLAND—*College Park*: H. J. Patterson.*
- MASSACHUSETTS—*Amherst*: H. H. Goodell.*
- MICHIGAN—*Agricultural College*: C. D. Smith.*
- MINNESOTA—*St. Anthony Park, St. Paul*: W. M. Liggett.*
- MISSISSIPPI—*Agricultural College*: W. L. Hutchinson.*
- MISSOURI—*Columbia*: H. J. Waters.
- MONTANA—*Bozeman*: S. M. Emery.*
- NEBRASKA—*Lincoln*: T. L. Lyon.
- NEVADA—*Reno*: J. E. Stubbs.*
- NEW HAMPSHIRE—*Durham*: C. S. Munkland.†
- NEW JERSEY—*New Brunswick*: E. B. Voorhees.*
- NEW MEXICO—*Mesilla Park*: F. W. Sanders.
- NEW YORK—*Geneva*: State Station; W. H. Jordan. *Ithaca*: Cornell University Station; I. P. Roberts.*
- NORTH CAROLINA—*Raleigh*: G. T. Winston.†
- NORTH DAKOTA—*Agricultural College*: J. H. Worst.*
- OHIO—*Wooster*: C. E. Thorne.
- OKLAHOMA—*Stillwater*: J. Fields.*
- OREGON—*Corvallis*: T. M. Gath.*
- PENNSYLVANIA—*State College*: H. P. Armsby.*
- RHODE ISLAND—*Kingston*: A. A. Brigham.
- SOUTH CAROLINA—*Clemson College*: H. S. Hartzog.*
- SOUTH DAKOTA—*Brookings*: J. H. Shepard.*
- TENNESSEE—*Knoxville*: R. L. Watts.‡
- TEXAS—*College Station*: J. H. Connell.*
- UTAH—*Logan*: L. Foster.*
- VERMONT—*Burlington*: J. L. Hills.*
- VIRGINIA—*Blacksburg*: J. M. McBryde.*
- WASHINGTON—*Pullman*: E. A. Bryan.*
- WEST VIRGINIA—*Morgantown*: J. H. Stewart.*
- WISCONSIN—*Madison*: W. A. Henry.*
- WYOMING—*Laramie*: E. E. Smiley.*

* Director.

† Assistant director in charge.

‡ Acting director.

§ Chairman of council.

|| Secretary.

EXPERIMENT STATION RECORD,

EDITED BY

A. C. TRICE, Ph. D., *Director,*

AND

E. W. ALLEN, Ph. D., Assistant Director—Chemistry, Dairy Farming, and Dairying.
W. H. BEAL—Meteorology, Fertilizers and Soils (including methods of analysis),
and Agricultural Engineering.

WALTER H. EVANS, Ph. D.—Botany and Diseases of Plants.

C. F. LANGWORTHY, Ph. D.—Foods and Animal Production.

E. V. WILCOX, Ph. D.—Entomology and Veterinary Science.

R. A. EMERSON—Horticulture.

J. I. SCHULTE—Field Crops.

With the cooperation of the scientific divisions of the Department and the Abstract
Committee of the Association of Official Agricultural Chemists.

EDITORIAL NOTES.

	Page.
The reading course as a factor in agricultural education.....	1
Agricultural experiment stations in Japan.....	101
Irrigation investigations.....	201
An Egyptian school of agriculture.....	202
The late Dr. E. Lewis Sturtevant.....	301
National Society of Agriculture in Egypt.....	303
The late Senator Justin S. Morrill.....	501
Experiment-station movement in Russia.....	601
Present status of the experiment stations in Russia.....	603
Agricultural experiment station in Alaska.....	701
Agricultural appropriation act 1899-1900.....	801
Irrigation investigations of the Department of Agriculture.....	901
Statistics of land-grant colleges and agricultural experiment stations, 1898...	1003

SPECIAL ARTICLES.

Scandinavian seed-control stations, F. W. Woll.....	4
Physical and meteorological researches, principally on solar rays, made at the station of agricultural climatology at the observatory of Juvisy, Camille Flammarion.....	103, 203
Official methods of analysis of fertilizers and feeding stuffs adopted by the Belgian State laboratories and the agricultural experiment stations of Holland.....	301
Biological and dairy building of New York State Experiment Station.....	401
Convention of Association of Official Agricultural Chemists, 1898, W. H. Beal.....	504
Twelfth annual convention of the Association of American Agricultural Col- leges and Experiment Stations, W. H. Beal.....	704
Investigations on the metabolism of milk cows, Oscar Hagemann.....	803, 903

LIST OF STATION PUBLICATIONS ABSTRACTED.

	Page.
ALABAMA CANEBRAKE STATION:	
Bulletin 18, March, 1895	816, 851, 896
Twelfth Annual Report, 1897	628, 693, 697
ALABAMA COLLEGE STATION:	
Bulletin 89, January, 1898	37
90, January, 1898	169
91, February, 1898	131
92, April, 1898	125
93, April, 1898	577
94, June, 1898	552
95, August, 1898	738
96, August, 1898	837
97, September, 1898	892
98, November, 1898	1041
99, December, 1898	1051
Tenth Annual Report, 1897	1097
ARIZONA STATION:	
Bulletin 27, December, 1897	124
28, March, 1898	420
29, June, 1898	851
ARKANSAS STATION:	
Bulletin 19, January, 1898	48
50, January, 1898	512
51, May, 1898	595
52, July, 1898	673
53, September, 1898	913
54, December, 1898	1085, 1089
55, December, 1898	1044
CALIFORNIA STATION:	
Bulletin 120, March, 1898	55
121, August, 1898	617
Exchange Seed List, March, 1898	361
Seed Bulletin, 1898-99	963
Report, 1895-1897	220, 222, 223, 224, 225, 228, 229, 235, 241, 245, 246, 250, 253, 254, 255, 258, 262, 267, 274, 276, 285, 297, 298
COLORADO STATION:	
Bulletin 41, February, 1898	266
42, February, 1898	240, 246
43, March, 1898	372, 374
44, March, 1898	521
45, May, 1898	597
46, June, 1898	743
47, July, 1898	770
48, 1898	795
49, September, 1898	1018, 1019, 1030
CONNECTICUT STATE STATION:	
Bulletin 125, April, 1898	60
126, May, 1898	374
127, May, 1898	337
Twenty-first Annual Report, 1897	214, 218, 229, 232, 242, 246, 253, 258, 261, 262, 265, 267, 273, 276, 280, 285, 295, 297
CONNECTICUT STORRS STATION:	
Bulletin 18, December, 1897	884
Tenth Annual Report, 1897	616, 663, 664, 678, 681, 683, 693, 697

DELAWARE STATION:		Page.
Bulletin 36, 1897	131

EXPERIMENT STATION RECORD,

EDITED BY

A. C. TRUE, PH. D., *Director*.

AND

E. W. ALLEN, PH. D., Assistant Director—Chemistry, Dairy Farming, and Dairying.
W. H. BEAL—Meteorology, Fertilizers (including methods of analysis), Soils, and
Agricultural Engineering.

WALTER H. EVANS, PH. D.—Botany and Diseases of Plants.

C. F. LANGWORTHY, PH. D.—Foods and Animal Production.

F. C. KENYON, PH. D.—Entomology and Veterinary Science.

R. A. EMERSON—Horticulture.

J. I. SCHULTE—Field Crops.

With the cooperation of the scientific divisions of the Department and the Abstract
Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. X, No. 1.

	Page.
Editorial notes: The reading course as a factor in agricultural education.....	1
Scandinavian seed-control stations, F. W. Woll.....	4
Recent work in agricultural science	16
Notes.....	99

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

New method for water analysis—Application of oleic acid as an indicator in the quantitative determination of mineral matter, E. d'Huart.....	16
Percentage of phosphoric acid in potable waters, C. Lepierre.....	16
Note on the estimation of citrate-soluble phosphoric acid in Thomas slag, M. Passon.....	17
A new method for the estimation of starch in grains, L. Lindet.....	17
On the practical application of the refractometer in butter examination, A. J. Swaving.....	17
The examination of filled cheese, A. Devarda.....	18
A new drying oven with a constant temperature, M. C. Schuyten.....	18

BOTANY.

Notes upon bean and pea tubercles, B. D. Halsted.....	21
Some botanical notes on corn, L. H. Pammel and R. Combs.....	22

	Page.
ZOOLOGY.	
The jack rabbits of the United States	23
The jack rabbits of the United States, T. S. Palmer.....	25
METEOROLOGY.	
Oklahoma weather and crops for 1897, G. E. Morrow.....	26
Meteorological observations, J. E. Ostrander and A. C. Monahan.....	26
Solar and terrestrial magnetism in their relations to meteorology, F. H. Bigelow.....	26
WATER—SOILS.	
The soils of Tennessee, C. F. Vandertord.....	26
Drinking water, N. E. Wilson.....	31
Soil moisture, J. B. Weems and J. J. Edgerton	27
Mechanical analyses and water content of Wyoming soils, C. B. Ridgaway...	29
The electrical method of moisture determination in soils, F. D. Gardner.....	30
The chemical composition of Utah soils, J. A. Widtsoe.....	30
FERTILIZERS.	
On Wiborgh phosphate, its manufacture and agricultural value, L. F. Nilson.....	32
The assimilation of nitric acid as well as the action of different nitrates, W. Schneidewind	34
Report of analyses of commercial fertilizers for the fall of 1897, L. L. Van Slyke.....	36
Analyses of commercial fertilizers, B. W. Kilgore et al.....	36
The inspection of fertilizers in 1897, F. W. Morse.....	36
Bacteria obtained from manure and their physiological rôle in the decomposition of manure, S. A. Sewerin.....	35
FIELD CROPS.	
Cooperative experiments in agriculture, C. A. Zavitz.....	36
Experiments with cotton, J. F. Duggar.....	37
Red rice, W. R. Dodson.....	38
Sugar-beet investigations in Wisconsin during 1897, F. W. Woll.....	39
The sugar beet in Pennsylvania, H. P. Armsby.....	40
Report on the results obtained with sugar cane on the experimental fields at Dodds's Reformatory, 1896, J. R. Bovell and J. P. d'Albuquerque.....	40
The cultivated vetches, J. G. Smith.....	43
Variety tests of wheat, oats, and potatoes, G. C. Watson and E. H. Hess.....	41
Manning meadows, L. Grandeau.....	42
HORTICULTURE.	
Vegetable tests of 1897, L. R. Taft, H. P. Gladden, and M. L. Dean.....	47
Preliminary report on Arkansas seedling apples, J. T. Stinson.....	48
Fruit growing in Wyoming, B. C. Buffum.....	44
The culture of native plums in the Northwest, E. S. Goff.....	45
Notes on pruning, F. W. Card.....	45
Results of thinning fruit in 1897	46
Stimulating and holding fruit buds, H. E. Glazier.....	46
Strawberries and grapes, H. E. Glazier	46
Strawberry growing in New Hampshire, F. W. Rane	48
Cooperative experiments with small fruit, D. T. Price.....	48
Raspberries, blackberries, and grapes, L. R. Taft and H. P. Gladden.....	48
Report of South Haven Substation	49
Hybrid roses, gooseberries, and strawberries, J. L. Budd	47

FORESTRY.

	Page.
Notes on the annual growth of forest trees, W. R. Lazenby	50
Forestry conditions and interest of Wisconsin, F. Roth	51
Forest growth and sheep grazing, F. V. Coville	52

SEEDS—WEEDS.

Report of the Danish seed control for 1896-97, O. Rostrup	53
Seed testing, C. R. Ball	54
Dodders infesting clover and alfalfa, L. H. Dewey	54

DISEASES OF PLANTS.

The alfalfa leaf spot disease, R. Combs	58
The olive knot, F. T. Bioletti	55
A destructive disease of maize, M. Raeborski	56
The diseases of the sugar cane in Java, J. H. Wakker and F. A. F. C. Went ...	56
<i>Rhizoctonia strobil</i> , a new disease of <i>Pinus strobus</i> , E. Scholz	57
On the viability of the winter spores of certain rust fungi, J. Eriksson	57
Annual report of the superintendent of spraying for Ontario, 1897	58
Preparation and application of fungicides, W. C. Sturgis	60

ENTOMOLOGY.

Proceedings of the ninth annual meeting of the Association of Economic Entomologists	60
Revision of the Tachinidæ of America north of Mexico, D. W. Coquillett ...	66
On the biology of <i>Oeneria dispar</i> in Russia, N. Kulagin	66
The San José scale, H. Osborn	68
A remedy for trial in the destruction of the worm of the vine (<i>Cochylis</i>), J. Dufour	67

FOODS—ANIMAL PRODUCTION.

Comparison of the thermogenetic or dynamogenetic power of simple food stuffs, with their nutritive value, A. Chauveau	70
The importance of asparagin for animal nutrition, M. Chomsky	71
Examination of Swedish fodder plants, IV, A. G. Kellgren and L. F. Nilson ...	72
The cooking of meat	73
Pig-feeding experiments, J. Klein	73
Pig-feeding experiments, J. Klein	74
Horse feeding: Tests of the digestibility of oats, hay, and the "new corn product," H. J. Patterson	75
Poultry experiments, J. Dryden	77

DAIRY FARMING—DAIRYING.

Investigations on the care and keeping of milch cows, Baekhaus	83
On the influence of the food on the fat content of the milk, F. Friis	86
Obtaining milk under aseptic conditions, Baekhaus and W. Cronheim	87
Some new experiments in churning	88
Effect of period of lactation on milk and quality of butter, G. L. McKay and J. W. Wilson	89
Investigations on the utilization of casein, Baekhaus	89

VETERINARY SCIENCE AND PRACTICE.

On the result of the rinderpest investigations at Koch's experiment station in Kimberly	91
The sheep fluke, N. A. Cobb	93
Contribution to the natural history of <i>Trichina spiralis</i> , J. Y. Graham	93
Tuberculosis in cattle and tuberculin, Nocard	94

STATISTICS—MISCELLANEOUS.

EXPERIMENT STATION RECORD.

VOL. X.

No. 1.

Among the many important agencies for agricultural education in this country must be counted the form of university extension work in which home-reading courses are conducted on the Chautauqua plan. The encouragement of agricultural education by this means has been undertaken by several of the agricultural colleges, and with such success as to demonstrate its practicability and value. The interest aroused in systematic reading along definite lines has had a beneficial effect upon the reader, apart from the information gathered, in cultivating the habit of thoughtful reading and in teaching him how to help himself. Not infrequently it has had the effect of arousing in the pupil a desire for college education or at least of helping him to appreciate the benefits of college training. This is a matter of unusual importance in the case of agriculture, as one of the difficulties met with in attracting students to courses in agricultural colleges has been the disparaging of "book farming" by farmers and the failure of the farmer's boy to realize the value to himself of an agricultural course—that there is anything in farming beyond what his father can teach him.

The interest which has been aroused in reading courses where systematic effort has been given to their inauguration has been quite remarkable. The success of the enterprise in the State of New York, where this and other forms of university extension among farmers have been most extensively undertaken, has been especially striking and its results are likely to be very far-reaching. That there is an increasing demand for education by this means is also shown by the year's experience of Cosmopolitan University, which is devoted entirely to instruction through the medium of correspondence. Although in operation less than one year, this institution now has upon its rolls nearly 20,000 students, distributed throughout the United States, Central America, and Canada, who are pursuing courses of reading in a wide range of subjects, under the direction of a faculty located at the university. This faculty numbers fourteen, besides assistants, and their instruction is given entirely through correspondence with the individual pupils. Indeed the instruction is more individual than in ordinary school work, for the individual circumstances and capabilities of the pupils have to be learned and taken into account in assigning and directing the work.

Among its numerous departments the university has one for agriculture, which has met with such success as to be of interest to students of agricultural education. It is especially encouraging as showing the desire for agricultural education by a large body of people who are unable to take up even the short courses offered by so many of the agricultural colleges. This department is presided over by Dr. Lewis McLouth, formerly president of the South Dakota Agricultural College. The field of agricultural science and art has been divided and subdivided under numerous heads, and general and special courses planned to suit the varied demands of pupils. These cover the whole range of the subject, from climate and soil, plant production, animal production, and agricultural industries, to agricultural engineering and business management. In planning these courses and selecting books for the reading, Dr. McLouth has had the counsel of various educators in this field and of specialists. The number of excellent books on various phases of agriculture which have been published during the past few years has been a great aid to this work.

The announcement of the agricultural department states that—

“The need of the average farmer of to day is undoubtedly the power to take a comprehensive view of the agricultural possibilities of his own surroundings. This is obtainable only by study over a field broad enough to enlarge the limited horizon of everyday practical experience. The problem which he must have clearly in mind is, What is the utmost I can do with my present surroundings?”

“Thinking brains and trained hands are necessary to success in farming as in all occupations; but the power of good thinking can come only from a thorough analysis and complete understanding of the subject. The science and practice of farming, in its highest form, finds scope for as much knowledge and trained skill as any of the so-called ‘learned professions.’”

It is to assist those who are debarred by circumstances from attending an agricultural college but who feel the need of this technical training that the agricultural department of the university is striving. It is gratifying to note that although this department has been organized but a few months nearly 200 persons have taken up the agricultural course, and the interest and enthusiasm displayed by a considerable proportion is most hopeful. These pupils have been drawn from nearly all the walks of life—professional men, retired business men, horticulturists, nurserymen, farmers and breeders, mechanics, clerks in stores, farm laborers, factory operatives, etc. Both sexes and nearly all ages are represented. Each reader is invited to send to the university once a month a written abstract or synopsis of his month's reading for discussion and criticism. At the completion of each course examinations are taken if the reader desires. Questions may be freely asked by pupils at any time concerning difficulties in the reading or in any way bearing upon the subject-matter of study. There are no fees of

any sort. The only expense to the reader is that for books and postage. "The sole conditions of membership are earnestness and reasonable preparation." The entire enterprise is declared by the founder of the university to be a benevolent one, and the expense of conducting it is at present borne by him.

No attempt is made to compete with or take the place of existing means of education. The aim of the university is "to fill a gap in existing means of education, and to bring an opportunity for liberal education, in the true sense of the term, within the reach of all who are unable, because of financial or family reasons, to attend established colleges." Persons whose circumstances and means are such as to enable them to attend the regular schools and colleges are strongly advised to do so.

These various efforts which are being made for popular education in agriculture recognize the fundamental fact that the length and expense of a four years' college course is an insurmountable barrier to the average farmer's son; and the earnestness with which the opportunities offered are being embraced in many localities is a recognition of the rapidly increasing evidence that the farmer needs special training for his occupation. While it is not pretended that the reading course will take the place of the more thorough instruction in agriculture, it will be far better than no course at all. It will open the mind of the pupil to the wonderful progress which is being made in agricultural science and practice. It will enable him to take more thorough advantage of the information furnished through books, bulletins of experiment stations, agricultural papers, farmers' institutes, etc. And it may prove an incentive to keep those boys on the farm who are fitted to get the most in every way out of a farmer's life.

SCANDINAVIAN SEED-CONTROL STATIONS.

F. W. WOLL, M. S.,

Assistant Professor of Agricultural Chemistry, University of Wisconsin.

The plan of establishing special seed-control stations began to be discussed in the Scandinavian countries at about the same time that it was in Germany, viz. in the early part of 1869, but the latter country led in the realization of the plan by nearly two years. The seed-control station at Tharand, Saxony, was established by F. Nobbe in May, 1869, while that at Copenhagen, Denmark, was opened in February, 1871, by E. Möller-Holst. The Danish seed control celebrated its twenty-fifth anniversary in 1896, on which occasion a special report on Danish seed control, 1871-1896,¹ was prepared for publication by the present director of the station, O. Rostrup, containing an account of the activities of the station since its establishment, and a statement of the present methods of seed analysis followed by the station. Much of the information given in the present article is gleaned from this report and from B. Jönsson's exhaustive paper on the history and present condition of the seed control.² The annual reports and other publications of the various stations have furthermore been drawn upon for information concerning the work done by the stations.

The other Scandinavian countries did not organize seed-control stations until several years after the establishment of the Danish station, viz. Sweden in 1876 and Norway in 1884. The two stations of this kind existing in Finland date from 1880 and 1882. (See p. 7.)

The conditions which brought into existence the seed-control stations in the countries named were similar to those found in other countries where such stations were established. Since these conditions are well known to students they need not be considered in detail here. Many kinds of seed sold in the Scandinavian countries during the early stages of the seed control were imported from Germany or surrounding countries, and the frauds described by Nobbe and other early champions of seed control in Germany were also found in the Scandinavian countries, including the use of powdered quartz, white or artificially colored, of any shade desired as an adulterant of clover seed, known to the trade as "Bohemian Mountains;" peat dust for adulterating timothy seed; bleaching of seed; admixtures of killed

²K. Landt. Akad. Handl. Tidskr., 33 (1894), pp. 257-286, 321-372 (E. S. R., 6, p. 945).

seed of *Plantago lanceolata* in red clover seed; of charlock and white mustard seed in turnip, rape, or cabbage seed, etc. Besides seed containing worthless adulterations or foul weed seeds, old and inferior seed true to name or seed mixed with that of other cultivated plants of less value was imposed upon an unsuspecting or patient public in much the same way that is possible under present conditions in this country. It was found also that seed which could not be sold in countries where seed control had been established was exported to countries where there was no such control and found a ready market there, until these countries partly as a matter of self-protection founded similar institutions.

The effect of the work of the Danish seed-control station became noticeable almost immediately after the establishment of the station, especially as regards the purity of the seed examined. The quality of the seed on the market, as is shown in the average purity and germination of the seed samples analyzed, has been gradually improved from year to year since the work of the station began, and is now of a very high order.

Selecting a dozen of the more common kinds of seed of legumes and grasses for comparison, we have in illustration of the fact stated the data presented in the following table, which has been compiled from the summary statements published by the station:¹

Summary of results of Danish seed analyses, 1870-1896.

PURITY OF SEED.

² The figures added represent the percentage of hard seed.

HISTORY OF SEED CONTROL IN SCANDINAVIA AND FINLAND.

Denmark.—As already stated, the first seed-control station in Denmark was established in Copenhagen in 1871. This was at first a private enterprise and was conducted for several years at a pecuniary loss, being maintained through the public spiritedness of its founder, E. Möller Holst. The State Agricultural Society in 1881 made an annual appropriation of 1,000 and later of 2,000 crowns (§268 and §536, respectively) for the support of the institution, and in 1883-84 the Government appropriated 2,000 crowns, which was increased in 1886 to 5,000 crowns (§1,340) annually. The State did not, however, assume full control of the station until 1891, when the present incumbent, O. Rostrop, was appointed director. The government of the station is in the hands of a seed-control commission of five members, appointed by the State, which determines the policy and the working rules of the station.

The number of seed samples analyzed by the Danish seed-control station since its establishment aggregates 30,897. The average number of samples analyzed annually has during late years approximated 1,800. The Copenhagen seed-control station is the only public institution of its kind in Denmark.

Sweden.—The first Swedish seed-control station was established in Halmstad in 1876. Later other stations came into existence, as shown in the following statement, furnished through the kindness of Dr. Jönsson, director of the Lund seed-control station.

Swedish seed-control stations, 1896.

County (län).	Location.	Director.	Year of establishment.	Number of analyses made in 1895.
Halland	Halmstad	E. Lyttkens	1876	246
Kalmar	Kalmar	A. Atterberg	1877	603
Skaraborg	Skara	O. Nylander	1877	32
Westmanland	Westerås	J. O. Bergstrand	1877	150
Stockholm	Stockholm	O. Sjöernquist	1878	1,001
Ostergötland	Linköping	C. A. Bhm	1878	401
Kristianstad	Kristianstad	L. J. Wahlstedt	1879	345
Göteborg and Bohuslän	Göteborg	J. E. Alen	1879	261
Oerebro	Oerebro	J. Widen	1880	831
Malmöhus	Lund	B. Jönsson	1880	1,255
Westerhotten	Umeå	C. N. Pahl	1880	39
Jemtland	Öpe	J. F. Broman	1881	137
Upsala	Upsala	F. von Post	1882	345
Jönköping	Jönköping	R. Tolf	1882	365
Gefleborg	Gefle	A. Westman	1883	189
Västernorrland	Hernösand	C. G. Strömkirk	1883	434
Södra Ellsberg	Boras	A. W. Essen	1885	210
Norrhotten	Luleå	P. Hellström	1889	58
Gotland	Hemse	T. A. Sätervall	1889	39
Värmland	Molkom	J. A. Andersson	1891	215

A number of the twenty seed-control stations in operation at the present time are combined with "chemical stations" under the same director. They are supported partly by State and county aid, partly by the income from analysis fees. The State appropriation varies from 350 to 850 crowns (§93.80 to §227.80) annually to the various stations, or 10,000 (§2,680) in the aggregate. In a few cases, e. g., Lund, the

director is dependent upon the analysis fees as payment for his services. The stations presenting a full report of their receipts and expenditures during 1894-95 received from 57.8 crowns (Luleå) to 2,071.58 crowns (Stockholm) in analysis fees (equivalent to \$15.49 to \$555.28, respectively). The stations report to the State Agricultural Department (*Kongl. Landbruksstyrelsen*) and work under the regulations prescribed by the Department.

The total number of seed samples analyzed annually by the stations has of late years exceeded 6,000. In 1894, 6,581 samples were analyzed, and in 1895, 7,078 samples. Of the latter number, 2,466 samples were analyzed for farmers, 3,770 for seedsmen, and 842 samples were bought in the open market by the stations themselves; 5,153 complete and 1,925 partial analyses were made. In addition to this analytical work a majority of the stations furnish to seedsmen tags guaranteeing the quality of seed in bags from which samples are drawn and analyzed.

Finland.—Two seed-control stations are in operation in Finland, one in Helsingfors and one in Aabo, established in 1880 and 1882, respectively. Both stations are operated in connection with a chemical station, and are supported partly by the Government and partly by annual grants from the city in which each is located. The number of analyses (including chemical analyses) made during 1895 at the Helsingfors station is given as 2,435, 412 being seed analyses. At Aabo 1,066 analyses were made in 1895, of which number 225 were seed samples.

Norway.—Official seed control was organized in Norway in the beginning of 1884, when the seed-control station at Haug was established by the Agricultural Society of Kristians amt (county). Later (in 1886) control stations were established in Christiania, Hamar, and Trondhjem, and the station at Haug was discontinued. The Christiania station is largely supported by an annual appropriation from the patriotic Society for Norway's Weal (*Selskab for Norges Vel*), while the other stations have small subsidies from the counties in which they are located and are primarily dependent for their support on the analysis fees received.

The number of analyses made at the Christiania control station during the decade 1886-1897 aggregates 2,029, viz, 1,724 complete and 305 partial analyses. About 200 samples are analyzed annually.

METHODS OF ANALYSIS.

The methods of analysis in vogue in the seed-control stations of the Scandinavian countries were worked out by representatives of the three countries, constituting the Scandinavian seed-control committee, in meetings held in Copenhagen in the latter part of 1890. The rules proposed by this committee were subsequently approved by the respective government authorities, with but insignificant changes. The methods and regulations concerning the seed control have therefore during late years been essentially the same in all the Scandinavian countries and in Finland as well. A summary of the methods of analysis and the regulations governing the seed control in these countries is given below.

A complete seed analysis includes determinations of (1) genuineness, (2) purity, (3) weight, and (4) germination. If partial examinations are desired covering one or more points, the fact that such examinations alone have been made, and that the certificate does not give any guaranty for the general quality of the seed, is to be expressly stated.

(1) *Genuineness*.—The genuineness of the seed is determined by the aid of the standard seed collection of the control station or the seed manuals. Both popular and Latin names of the seed examined are given in the certificate, and, so far as practicable, also the variety and cultural form.

(2) *Purity*.—The purity of the seed is determined in average weighed samples by hand picking or screening. As the lower limit for the size of the sample used for this purpose the average dry weight of 1,000 seed multiplied by 10 is generally taken. An exception is made in case of seed a hectoliter of which weighs more than 25 kg. For such seed the lower limit is found by multiplying by 5. The sample must never weigh less than 2 gm. and for large seeds like beans, etc., at least 300 gm. is required.

In purity determinations the seed is separated into (1) pure seed and (2) impurities. The latter include (a) offal (fragments of plants and seeds, dirt, sand, stones, etc.), (b) foreign culture seed, and (c) weed seed. The quantities of these different components are determined by weighing, and are given on the certificate issued, calculated to per cent of the seed. The weed seeds are separated into harmless and noxious seed. Under the latter are included the following 14 kinds in addition to rust spores and sclerotia: *Agrostemma githago*, *Bromus secalinus*, *Banias orientalis*, *Centaurea cyanus*, *Chrysanthemum segetum*, *Cirsium arvense*, *Oxycystis trifolii*, *Matricaria inodora*, *Ranunculus repens*, *Raphanus raphanistrum*, *Rhisanthus crista galli*, *Sinapis arvensis*, *Brassica campestris*, and *Sonchus arvensis*.

(3) *Weight*.—For the determination of the dry weight of 1,000 seeds three lots of 200 seeds of the thoroughly mixed sample of pure seed are counted and weighed. The fresh weight of 1,000 seeds is found by multiplying by 5. If the parallel determinations differ more than 5 per cent for small seed (i. e., average dry weight per 1,000 seeds below 5 gm.) and 10 per cent for large seed (i. e., average dry weight per 1,000 seeds over 5 gm.) the determinations are repeated. A dry-matter determination is then made of the sample of pure seed by grinding 10 to 20 gm. of large seed in a small mill and weighing out 2.5 gm. of the ground seed. In case of small seed 1 gm. of whole seed is weighed out. These quantities are dried for 4 hours in a steam oven. The percentage of dry matter thus found, multiplied by the fresh weight of 1,000 seeds, gives the dry weight of 1,000 seeds, which is reported with 3 decimals in the analysis certificate.

The determination of the hectoliter weight of cereals and legumes is obligatory in case of complete analysis, the result being expressed with 3 decimals.

(4) *Germination*.—The three samples of 200 seeds each used for the determination of the fresh weight are taken for this determination. If the parallel results calculated in percentage of pure seed do not come within 6 per cent a new germination test is made. For this determination such methods, apparatus, temperature, etc., are adopted as will give the highest and most uniform results in each particular case. The seed may be soaked in water for 10 minutes prior to being placed in the germination apparatus. Of late years soaking has, however, generally been abandoned, as it has been found of no advantage in hastening the germination.

The germination test is discontinued at the end of the number of days given below, in case of the various kinds of seed:

	Days.
Cabbage, radish, mustard.....	8
Spargula, barley, rye, wheat, timothy, flax, kidney vetch, birds' foot trefoil, lupine, medick, bean, pea, clover, bean vetch (<i>Vicia faba</i>), buckwheat.....	10
Common oats, Tartarian oats, lentil, lathyrus, Orobus, vetches (exclusive of <i>Vicia faba</i>).....	12
Fiorin grass, foxtail, tall oat grass, yellow oat grass, reed canary grass, Brachypodium, brome grass (<i>Bromus arvensis</i> and <i>B. mollis</i>), meadow fescue, reed meadow grass, rye grass, Schedonorus, esparcet, serradella, caraway, carrot, parsnip, etc.....	15
Aira, sweet vernal grass, quaking grass, crested dog's tail, orchard grass, lyme grass, hard fescue, giant fescue, <i>Festuca heterophylla</i> , sheep's fescue, red fescue, <i>Festuca sylvatica</i> , velvet grass, psamma grass.....	20
Meadow grasses (<i>Poa</i> spp.), seed of most trees.....	25

Besides the germination proper, the so-called germinative energy, i. e., the number of seeds germinating in certain briefer periods of time, is given. These differ with different seeds, and are as follows:

	Days.
Lucern, yellow mustard, turnips.....	2
Red, white, and alsike clover, kidney vetch, ruta-baga.....	3
Black medick, spurry, timothy, brome grass (<i>Bromus arvensis</i> and <i>B. mollis</i>).....	4
Common and Italian rye grass, fiorin, tall oat grass, meadow fescue.	5
Carrot, fodder beet, meadow foxtail, velvet grass, Kentucky blue grass.....	6
Hard fescue, orchard grass.....	7
Meadow grass (<i>Poa</i> spp.).....	8

In regard to the germinative energy of seed of different age Möller-Holst found that Scandinavian seeds germinate better and more rapidly in the spring than during the preceding fall, but as a rule the germinative energy continues to increase during the following six to twelve months. As long as this is the case the seed can not properly be called old, even if they have lost their brightness and color, which is apt to happen, particularly with white-clover seed. It was found that the germinative energy increased during five to fifteen months after the first germination test was made for red clover, white clover, alfalfa, caraway, barley, orchard grass, and common rye grass.

(5) *Hard seed.*—The hard seed of legumes and nongerminated seed of very slowly germinating tree seed, which prove viable on being cut open, are given in a special column as “hard.” Other seeds which have not germinated are given as “dead.” The germination of beet seed is calculated in percentage of viable bolls.

The proportion of hard seeds in seed of leguminous plants has been determined at the Danish seed-control station since the summer of 1874. Experiments in the open field having shown that about half of the hard seeds germinated during the summer, the percentage of germination is increased by one-half the percentage of hard seeds. Since 1887 the percentages of germinated and hard seeds have been given separately in the analysis certificates, and according to common usage in Denmark the viability of a sample of leguminous seeds has come to mean the sum of the germinated and hard seeds. In the other Scandinavian countries and in Finland only one-third of the hard seeds are as a rule considered viable.

A greater proportion of hard seeds is found soon after harvest than later on, the proportion decreasing somewhat in the course of the winter. The samples of red, white, and alsike clover analyzed at the Danish station during the year 1886–87 contained on an average the following percentages of hard seed: November, 16 per cent; December, 12 per cent; January, 10 per cent; February, 9 per cent; March, 9 per cent; April, 9 per cent; and May, 9 per cent.

The germinative ability of hard seeds increases with age, but the method of keeping the seed has a marked influence, a dry, warm atmosphere being favorable to the preservation of their hardness.

Where the proportion of hard seeds approaches 20 to 30 per cent or exceeds these figures, as is often the case with white and alsike clover, the matter of hard seeds becomes one of great importance. Under ordinary conditions and with other leguminous seeds the depreciation from this cause is considerable.

Efforts have been made to prepare hard seed so as to secure perfect germination, but they have not been altogether successful until lately. The seed-coat crusher (*fröpräparator*) constructed by N. Hj. Nilsson, director of the Svalöf seed station in Sweden, may be said to have practically solved the problem. The seed crusher consists of an emery cylinder, which is rotated at the rate of 3,200 revolutions per minute. The seed passing through the machine is thrown against the cylinder and its seed coat scratched so as to readily permit the entrance of water to the germ of the seed.

The earlier form of the machine worked in a satisfactory manner, but its capacity was too small, viz, only one to one and one-half bags of seed (100 to 150 kg.) per day. The machine as now perfected and manufactured has a capacity of 100 to 200 kg. per hour, according to the kind of seed treated. The price of the seed machine, which is patented, is 300 crowns (\$81). The treatment by the process has been

found to have no injurious effect on the seed. The machine has been generally adopted by Scandinavian seedsmen.

Germination tests of seeds before and after being run through the "Nilsson" or "Svalöf" seed-coat crusher show the great improvement resulting from this treatment. The Copenhagen station has published the following results: Red clover containing 25 per cent of hard seed—germination before treatment (in three days), 61 per cent; after treatment (in three days), 96 per cent. White-clover seed containing 34 per cent of hard seed—germination before treatment (in five days), 62 per cent; after treatment (in three days), 99 per cent. Alsike clover seed containing 66 per cent of hard seed—germination before treatment (in four days), 27 per cent; after treatment (in three days), 98 per cent.

LATITUDE ALLOWED IN SEED ANALYSIS BY THE DANISH SEED-CONTROL STATION.

The latitude allowed in seed analysis for purity is 2 per cent; for germination of pure seed, 3 per cent in case of over 95 per cent germination, 4 per cent in case of 90 to 95 per cent germination, and 5 per cent below 90 per cent germination; for germination of seed purchased (pure viable seed), 5 per cent; for grain weight, 6 per cent for leguminous seed and 10 per cent for grass seed; for weed seed, 0.3 per cent (see below).

The amount of discount per pound to be allowed for deficiency in purity and germination is calculated as follows:

$$\text{Discount for impurity} = \frac{\text{Deficiency per cent} \times \text{price per pound}}{\text{Guaranteed purity}}$$

$$\text{Discount for deficient germination} = \frac{\text{Deficiency per cent} \times \text{price per pound}}{\text{Guaranteed germination}}$$

Hard seeds.—If certain percentages of hard and of viable seeds are guaranteed the hard seeds are calculated as equal to one-third the value of the viable seeds, unless another relation is agreed upon at the time of the sale.

Weight.—For each deficient per cent a discount of one-half of 1 per cent of the price of the seed is given.

Weed seeds.—For the deficiency, calculated in percentage of the seed, 15 per cent of the cost of the seed is deducted for each per cent of weed seeds unless these are harmless. In such case the discount is given for a possible excess of impurities. If the seed is guaranteed free from noxious weeds beyond a certain maximum, a content of 100 dodder seeds and 200 other foul weed seeds per kilogram beyond this maximum is allowed. In case of a greater content of weed seeds a discount of 2 per cent of the cost of the seed per kilogram is given for each 100 and 200 weed seeds, respectively, contained therein beyond the maximum quantity allowed, the greatest discount allowed being 25 per cent of the cost of the seed.

GERMINATION APPARATUS.

The Nobbe clay disks are used to some extent in a number of Scandinavian seed control stations, but where a large number of analyses are made either the Jacobsen or the Strokirk germination apparatus is used. The former (fig. 1), constructed by C. P. Jacobsen, of Copenhagen, consists of a large, square, metal tank, in which are placed narrow glass plates (*a*). On these, round felt pieces are laid, which are connected with the water in the tank by means of small wicks. A

thick, loosely woven mat is placed on the felt, and on this again a piece of filter paper, upon which the seeds to be tested are spread. A small glass bell supplied with a narrow opening at the top, to provide for circulation of air, is placed over the disks. The disks of felt and the woven mat also have holes in the middle to facilitate circulation.

FIG. 1.—Jacobsen's seed-testing apparatus.

A gas burner (*c*) heats the water in the tank, and to distribute the heat more evenly a metal plate (*b*) rests loosely on small pillars, which support it a couple of inches above the bottom.

This apparatus is easily regulated as to moisture and temperature, is easily cleaned and examined, takes comparatively little room, and gives very satisfactory and comparable results. The two pieces of apparatus of this kind in use in the Danish seed-control station in 1896 had a capacity of 253 and 119 germination tests, respectively, at a time. The tank, disks, glass plates, etc., were cleaned with boiling water once every week, and the filter paper renewed every four days.

The temperature of the bath ranges from 15 to 26° C., the temperature during the night being 16 to 17° C. Experiments made with a view of finding a more favorable temperature have always given negative results, as shown in the following series of experiments made by the Danish seed control:

Effect of constant and variable temperatures on germination.

	Number of samples.	Viability at—	
		18–25° C.	Constant at 25° C.
Orchard grass.....	30	87.3	86.3
Common rye grass.....	14	83.5	81.9
Italian rye grass.....	10	82.5	82.1

These results corroborate those obtained by Stebler, who recommends on the average 19°, not higher than 26°, but where it is possible not below 15°.

TAGS FOR SEED IN BAGS.

A number of Swedish and Finnish control stations offer seedsmen an opportunity to guarantee the quality of their goods by furnishing tags for seed in bags which upon analysis has been found to come up to a certain standard. If a quantity of seed analyzed does not come up to the standard it can not be sold with station tags. The standards refer to the percentages of pure germinated seed in the goods, and are as follows:

Minimum pure germinated seed for goods supplied with control tags.

	Per cent.
(1) Cereals (straw and grain crops).....	90
(2) Fodder plants:	
Red clover.....	80
White clover, alsike clover, medick, kidney vetch.....	75
Brome grass (<i>Bromus arvensis</i> and <i>B. mollis</i>), meadow fescue, timothy, rye grass (<i>Lolium italicum</i> and <i>L. pratense</i>).....	80
Orchard grass, tall oat grass.....	65
Hard fescue, red fescue, sheep's fescue.....	60
Crested dog's tail, fiorin grass.....	55
Reed canary grass, <i>Aira caespitosa</i> , <i>A. flexuosa</i> , yellow oat grass, sweet vernal grass, meadow foxtail.....	40
Velvet grass.....	35
Meadow grass (<i>Poa</i> spp.).....	30
(3) Various crops:	
Rape (<i>Brassica</i> spp.).....	95
Spurry (<i>Spergula sativa</i> and <i>S. marima</i>), mustard.....	90
(4) Root crops:	
Mangel-wurzels, ruta-bagas.....	95
Beets.....	85
Carrots.....	55
(5) Tree seed: Conifers.....	70

The tags furnished give the main results of the analyses as follows: Name of seed, dry weight of 1,000 seeds, percentage of pure viable seed, hard seed, dead seed, chaff, dirt, etc., seed of other cultivated plants, weed seed, number of noxious weed seed per kilogram of sample, name of station, date, etc.

The Finnish stations, in addition to information similar to that given above (in Swedish and Finnish), give on the reverse of the tag the number of each of the following noxious weed seed found in 1 kg. of the seed, the names of the weed seeds being given in Latin, Swedish, and Finnish: *Agrostemma githago*, *Agrostis spica venti*, *Rumex crispus*, *R. domestica*, *Thlaspi arvense*, *Barbarea vulgaris*, *Cuscuta trifolii*, *Anthemis tinctoria*, *Matricaria inodora*, *Cirsium arvensis*, *Centaurea cyanus*, *Chrysanthemum leucanthemum*, *Bromus secalinus*, *Raphanus raphanistrum*, *Brassica campestris*, *Sinapis arvensis*, *Bunias orientalis*, *Sonchus arvensis*, and *Clari-ceps purpurea*.

The total amount of seed examined and supplied with tags during 1895 by the thirteen Swedish seed-control stations called upon to do this work was in the aggregate 1,599,141 kg., or over 14,000 bags. The two Finnish stations supplied tags for 6,529 bags of seed during 1895.

COST OF SEED ANALYSES.

The tariff of the Danish seed control for analyses of seed samples is as follows:

Tariff of the Danish seed control for seed analyses.

Determination of—	
Genuineness	1.0 crown=\$0.27
Hectoliter weight.....	1.5 do. = .40
Absolute weight	1.5 do. = .40
Purity of large seeds.....	2.0 do. = .54
Purity of small seeds.....	3.0 do. = .80
Number of <i>Cuscuta</i> seeds per kilogram.....	3.0 do. = .80
Pure viable seed, large seeds.....	4.0 do. = 1.07
Pure viable seed, small seeds.....	5.0 do. = 1.34
Complete analysis, large seeds.....	5.0 do. = 1.34
Complete analysis, small seeds.....	7.0 do. = 1.88

Seedsmen who offer farmers the privilege of free examination of seed purchased of them pay 3 crowns (80 cts.) for such complete analysis of large seeds and 4 crowns (\$1.07) for the other kinds of seed.

The tariff in force at Norwegian seed-control stations is lower than that of the Danish station, viz, complete analysis of seed offered for sale, 4 crowns (\$1.07); of that grown by the sender, 3 crowns (80 cts.); of that purchased for own use, 3.60 crowns (96 cts.).

Discounts are given to all parties whose annual analysis fees reach 50 crowns (\$13.40) as follows: For 50 crowns, 20 per cent; 55 crowns, 21 per cent; 65 crowns, 22 per cent; 80 crowns, 23 per cent; 100 crowns, 24 per cent; 125 crowns, 25 per cent; 155 crowns, 26 per cent; 190 crowns, 27 per cent.

Swedish seedsmen pay 3 crowns (80 cts.) for a complete seed analysis at their seed-control stations, 5 crowns (\$1.34) for determination of the different kinds of foreign seeds, and 25 öre (6.7 cts.) per tag furnished. Customers within the particular county in which the station is located and which contributes to the support of the station, pay only 1 crown (27 cts.) for a complete seed analysis, including determinations of genuineness, purity, and germination; and 5 crowns (\$1.34) for determination of different kinds of foreign seeds.

The tariff at the Finnish control stations is somewhat lower, viz, 3 Finnish marks (58 cts.) for a complete analysis of large seeds, 4 Finnish marks (77 cts.) for small seeds, and 20 penni (4 cts.) per tag furnished.

PERSONNEL AND EQUIPMENT.

The majority of the Scandinavian seed-control stations have one officer, the director of the station, or a director and assistant. A few

stations employ additional temporary help during the rush of the season. The largest Scandinavian seed station, the Danish seed control, is officered as follows: 1 director, 1 first assistant (bookkeeping and correspondence), 1 gardener, and 9 assistants; the latter and the first assistant are women.

The larger stations are supplied with Jacobsen's germination apparatus; others use that of Strokirk or Nobbe's plates. The Nobbe thermostat for seed examinations or larger thermostats are often found. Other apparatus met with are Stjernquist seed examiner, Stebler diaphanoscope, Sommer and Runge liter weight, Nobbe seed duster ("spreufge"), Svalöf seed-coat crusher, "seed horn," Maercker seed marker, analytical balance, microscopes, pocket lenses, sieves, etc.

As important as any of the preceding apparatus are the standard collections of pure seeds of cultivated plants and of the different weeds. These collections are invaluable for identifying foreign seeds in samples received for examination. Mention should also be made of the reference library with which the stations (or the officers privately) are supplied, consisting, first of all, of manuals on seeds and seed testing (Nobbe, Harz, Settegast), and of works on botany, microscopy, technology, etc.

Whenever tests are reported by any seed-control station, blanks are furnished stating the results of the examinations. These are generally reported on a printed form in which the percentages, etc., are tabulated so as to show the value of the seed at a glance.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

New method for water analysis—Application of oleic acid as an indicator in the quantitative determination of mineral matter, E D'HUART (*2. Congrès Internat. Chim. Appl., 1896, IV, pp. 289-293*).—In the method proposed oleic acid or olein and soda solution, used separately, are substituted for the soap solution ordinarily employed in testing the hardness of water. The method is as follows: To 50 cc. of water add a few drops of pure olein, and then slowly run in decinormal soda solution until a lather appears on shaking, which rapidly disappears on standing.

To another sample of 100 cc. of water add a few drops of hydrochloric acid and boil until the carbon dioxid is completely expelled. Cool, neutralize the acid carefully, evaporate to 50 cc., and test as above directed. The result thus obtained, subtracted from the first determination, gives the amount of soda equivalent to carbon dioxid in the water.

Boil a third sample of 50 cc. of water until the free carbon dioxid and that of the bicarbonates is driven off. Cool, filter, make up the volume to 50 cc. with distilled water, and test as before. This furnishes data for calculating the amount of carbon dioxid in the form of bicarbonate.

To a fourth sample of 100 cc. of water add sufficient ammonium oxybate to completely precipitate the calcium salts. Boil for half an hour, filter, cool, evaporate to 50 cc., and test as before to determine the equivalent in caustic soda of the magnesia present in the water. In comparative tests results obtained by this method agreed closely with those obtained by gravimetric methods.

Percentage of phosphoric acid in potable waters, C. LEPIERRE (*2. Congrès Internat. Chim. Appl., 1896, IV, pp. 267-272, dgms. 2*).—This is a study of the method proposed by Villiers and Borg.¹ As a result of the study, the following modification of the method is proposed: Evaporate 1 liter of water to dryness in a porcelain, or better in a platinum dish, with the addition of dilute nitric acid to separate the silica. Take up in nitric acid and evaporate again to dryness to remove the last traces of silica. Filter and wash until the filtrate amounts to 50 cc. and add 2 cc. of molybdic solution, prepared by dissolving 150 gm. of

¹ Bul. Soc. Chim. Paris, 9 (1893), p. 486 (E. S. R., 5, p. 519).

ammonium molybdate in 1 liter of water. The phosphoric acid is determined by comparing the coloration thus produced with that of standard solutions of phosphate to which an equal quantity of molybdic solution has been added.

Note on the estimation of citrate-soluble phosphoric acid in Thomas slag, M. PASSON (*Ztschr. Angew. Chem.*, 1897, No. 23, pp. 716-749).—Instead of the solution used by Wagner, the author recommends a solution containing 140 gm. crystallized citric acid and 30 gm. tri-potassium citrate in 1 liter. This solution gives results identical with the Wagner solution and is much easier to make. The tri-potassium citrate is prepared by adding to a solution of citric acid rather more than enough potassium hydrate to neutralize the acid, evaporating the solution on a water bath until it begins to crystallize, allowing it to cool, and then stirring until a complete crystallization has taken place. The mother liquor is then drawn off, the salt washed with as little water as possible until the alkaline reaction disappears, then several times with alcohol and ether, and finally dried between folds of filter paper.—J. B. LINDSEY.

A new method for the estimation of starch in grains, L. LINDET (*Ztschr. Angew. Chem.*, 1898, No. 7, p. 166).—Ten grams of the ground grain is treated for 24 hours at 40 to 50° C. with a solution containing 2 per cent of pepsin and 1.5 per cent of hydrochloric acid. The solution is then brought into a small sack made of fine bolting cloth (80 to 100 mesh) and suspended in water until the starch appears to be entirely removed. The water should be changed frequently during the washing. The combined waters are filtered through a tared filter to collect the starch. The paper should be dried, first at 50° C. and later at 105° C. to constant weight.—J. B. LINDSEY.

On the practical application of the refractometer in butter examination, A. J. SWAVING (*Landw. Vers. Stat.*, 49 (1897), No. 4-5, pp. 341-347).—The author states that shipments of pure butter from Holland and Friesland to England have repeatedly been held to be suspicious on account of being below the limit for volatile fatty acids adopted by English chemists. This difficulty, it is believed, could be avoided by the use of the refractometer, which is also a great saving of time.

The results are tabulated for 624 samples of butter examined with the refractometer and for volatile fatty acids. Of these, 353, or 56 per cent, showed a refractive index of 52.5° or less; and 127, or 20 per cent, showed a refractive index of 52.5 to 54°. These 480 samples were proved to be pure, natural butter. The remaining 144 samples, or 24 per cent, showed a higher refractive index (than 54°) and were in part identified as adulterated.

In the case of butter containing admixtures of other fats it is considered necessary to make an examination with the polarizing microscope, in addition to determinations of the volatile fatty acids and the

refractive index, to detect crystals of foreign fats. The refractive index and volatile fatty acids are given for a number of vegetable and animal fats, and the application of these data in the examination of mixed butters is described.

The examination of filled cheese, A. DEVARDA (*Ztschr. Analyt. Chem.*, 36 (1897), No. 12, pp. 751-766, fig. 1).—To obtain large quantities of cheese fat for investigation the following method is recommended: From 50 to 100 gm. of finely cut cheese is placed in a flask with 50 to 80 cc. water, 100 to 150 cc. ether, and 2 drops of phenolphthalein solution. The whole is vigorously shaken and dilute caustic potash added until the reaction is distinctly alkaline, when the shaking is repeated. After standing a short time the layer of fat solution may be drawn off, filtered, and dried at 100° C.

If the fat has been thus extracted, the Reichert-Meissl method is believed sufficient to indicate the presence of foreign fat.

Water is determined in the cheese by drying the finely cut sample 24 to 36 hours in vacuo over sulphuric acid at room temperature, completing the operation by heating to constant weight at 100° C., 2 to 6 hours being generally sufficient.

The cheese, after drying by the above-described method, is finely ground and extracted with water-free ether. The crude fat thus obtained is dried 2 hours at 100° C.—L. H. MERRILL.

A new drying oven with a constant temperature, M. C. SCHUYTEN (*Chem. Ztg.*, 21 (1897), No. 100, p. 1019, fig. 1).—This is on the principle of the water bath with a constant level. A double-walled drying oven is connected with an automatic constant-level reservoir of pure water by means of a connecting tube, which is provided with two stopcocks. One of these cocks is intended to establish connection between the oven and reservoir, and the other to allow egress of the liquid from the oven. Sodium nitrate is dissolved in the water to elevate the boiling point, the requisite amount being determined by trial. If the temperature of boiling is too low, more nitrate is added; if too high, some of the solution is drawn off and its place supplied with fresh water from the reservoir. When the desired point has been once reached and connection with the fresh-water reservoir established, the temperature remains constant. The temperature of boiling of the solution is constant so long as its density is constant, and this remains so indefinitely, inasmuch as the water lost by evaporation is renewed automatically from the fresh-water reservoir.—J. T. ANDERSON.

Second International Congress of Applied Chemistry, 1896 (*Deuxième congrès international chimie appliquée, 1896. Paris: Association des Chimistes de Sucrierie et Distillerie, 1897, 5 vols.*).—This contains a report of the proceedings of the congress and the papers presented, edited by F. Dupont. Volume I (pp. 721, ill.) contains reports of section 1 on sugar and section 2 on alcohol and fermented products; Volume II (pp. 544), of section 3 on agricultural industries, section 4 on agricultural chemistry, and section 5 on official analysis and apparatus of precision; Volume III (pp. 499, ill.), of section 6 on chemical industries, section 7 on photography, and sec-

tion 8 on metallurgy, mines, and explosives; Volume IV (pp. 659, ill.), of section 9 on chemistry applied to medicine, pharmacy, hygiene, and food, section 10 on electro-chemistry and electro-metallurgy, and section 11 on purification, etc., of water from manufactories. Volume V (pp. 360) contains a list of members and names of committees, with reports of excursions, etc.

Quantitative analysis of phosphates, R. M. CAVEN (*Jour. Soc. Chem. Ind.*, 16 (1897), pp. 208, 209; *abs. in Jour. Chem. Soc. [London]*, 74 (1898), No. 425, II, p. 187).

Kjeldahl's process, J. O. SULLIVAN (*Jour. Soc. Chem. Ind.*, 16 (1897), pp. 111, 112; *abs. in Jour. Chem. Soc. [London]*, 74 (1898), No. 425, II, p. 186).—The author used in the analysis of malt extract and ale a mixture of 1 part strong sulphuric acid and 2 parts of Nordhausen acid, adding 0.5 gm. of mercuric oxid at the beginning and completing the oxidation with potassium permanganate.

The use of mercuric chlorid for preserving samples of juice for analysis, H. COURTONNE (*2. Congrès Internat. Chim. Appl.*, 1896, I, pp. 251, 252).

Simple method for analyzing organic materials (butters, oils, waxes, hydrocarbons, essences, etc.), by the determination of the critical temperature of solution, L. CRISMER (*2. Congrès Internat. Chim. Appl.*, 1896, IV, pp. 273-288, *dgms.*, 2).

International agreement in agricultural analysis, H. W. WILEY (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 237-240).

On the analysis of beets, F. SACHS (*2. Congrès Internat. Chim. Appl.*, 1896, I, pp. 286-290, *figs.*, 2).

A method of analysis applicable to salt and crude potashes, F. JEAN (*2. Congrès Internat. Chim. Appl.*, 1896, III, pp. 20, 21).—Detailed directions are given for the analysis of mixtures of caustic alkalies, and alkaline chlorids, carbonates, and sulphates.

Commercial methods of analysis of flour and meal, M. ARPIN (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 58-63).

Note on the determination of metaphosphoric and pyrophosphoric acids in superphosphates, PIRON and NAY DE MÉZENGE (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 174-177).—The method proposed for the determination of metaphosphoric and pyrophosphoric acids is as follows: Digest 2.5 gm. of the superphosphate in a 250 cc. flask with 100 cc. of ammonium citrate for 12 hours. Make up the volume to 250 cc. with water and filter. To 100 cc. of the filtrate add a slight excess of nitric acid (about 15 cc.). Heat at a temperature near the boiling point for 1 hour, cool, and precipitate phosphoric acid in the usual way. The difference between the amount of phosphoric acid thus determined and that found by precipitation in 100 cc. of the filtrate in the usual manner, without treatment with nitric acid, gives the amount of metaphosphoric acid contained in the superphosphate.

The agricultural value of Thomas slag, CLUSS (*Ztschr. Angew. Chem.*, 1898, No. 11, p. 248).—The author describes a modification of the Wagner method for ascertaining the agricultural value of the phosphoric acid in Thomas slag. To 100 cc. of the usual citrate acid solution containing the slag is added 20 cc. of concentrated nitric acid, and the solution boiled in an Erlenmeyer flask until the volume is reduced to about 20 cc. Twenty-five cubic centimeters of concentrated sulphuric acid is then added, and the solution boiled (about 10 minutes) until the silica is deposited. The solution is then made to 250 cc., and the phosphoric acid estimated in 100 cc. of the filtrate.—J. B. LINDSEY.

Determination of nitrates by titration, J. COTRAIT (*2. Congrès Internat. Chim. Appl.*, 1896, II, p. 183).—The method employed is as follows: Place in a test tube 10 cc. of pure sulphuric acid and 10 cc. of the solution to be tested, covering the surface with a few drops of naphtha to exclude the air. Add a solution of ferrous sulphate until the brown coloration of the solution just becomes permanent. The ferrous sulphate solutions are made of different strengths, that of the more concentrated solutions being such that one-tenth of a cubic centimeter corresponds to 10 mg. of nitrate, while in case of the weaker solution it corresponds to 2 mg. of nitrate. From the amount of solution used the percentage of nitrate present is calculated.

Estimation of nitrates and nitrites as nitric oxid. J. CONTRAI *Ztschr. Angew. Chem.*, 1896, I, 9, No. 1, pp. 1-7.—An abstract of the preceding paper.

Determination of nitric acid by electrolysis. K. ULSCH *Ztschr. Elektrochem.*, 3, 1897, pp. 171-172; *Jour. Chem. Soc. [London]*, 74, 1898, No. 425, II, p. 47.—The nitrate dissolved in sulphuric acid is reduced to ammonia, using a copper cathode and platinum anode. The method described is applicable only to pure nitrates, since chlorides and other substances naturally occurring in nitrates interfere with its accuracy.

The direct determination of potassium carbonate in salt. A. AULARD *Congrès Internat. Chim. Appl.*, 1896, I, pp. 47-51.—This is Hoyer's method completed and modified in several points.

The determination of animal and vegetable fats. T. TAYLOR *Congrès Internat. Chim. Appl.*, 1896, II, pp. 1-3, p. 3.

Study on the determination of tannins. E. AGLOT *Congrès Internat. Chim. Appl.*, 1896, III, pp. 7-11.—See before.

Studies on the estimation of tannin. E. AGLOT *Ztschr. Angew. Chem.*, 1898, No. 1, pp. 17-18.—The author reviews the various methods employed for the estimation of tannin, calls attention to their weak points, and offers suggestions, based upon his work, for their improvement.—J. B. LINDSEY.

Determination of copper in vegetable substances. B. H. PAUL and A. J. COWNLEY *Rev. Internat. Falsif.*, 11, 1896, No. 2, p. 22; *abs. in Ztschr. Angew. Chem.*, 1898, No. 14, p. 27.

Detection of copper in canned peas. BODMER and MOOR *Rev. Internat. Falsif.*, 11, 1896, No. 2, p. 21; *abs. in Ztschr. Angew. Chem.*, 1898, No. 14, p. 26.

The determination of ergot of wheat in flour. A. MILLER *Rev. Internat. Falsif.*, 11, 1896, No. 2, p. 20; *abs. in Ztschr. Angew. Chem.*, 1898, No. 14, p. 28.

The detection of formic aldehyde in feeding stuffs. A. JORISSEN *Rev. Internat. Falsif.*, 11, 1896, No. 2, p. 12; *abs. in Ztschr. Angew. Chem.*, 1898, No. 14, p. 32.

The total nitrogen in urine. L. MONFET *Congrès Internat. Chim. Appl.*, 1896, IV, pp. 17-9.—A modification of the Kjeldahl method said to be very exact is reported. The substance is oxidized with fuming Nordhausen sulphuric acid and manganese dioxide, and the resulting ammonium sulphate is decomposed by means of a strong solution of alkaline sodium hypobromite, the resulting nitrogen being measured in a eudiometer.

On Fehling's solution. M. Z. JOVIT-CHITSCH *Neue Ztschr. Rübenz. Ind.*, 35, 1897, No. 20, pp. 272, 273.—The author shows that Fehling's solution is reduced by mineral acids, H_2SO_4 , HNO_3 , and HCl , when these are added in such quantities that the solution still gives an alkaline reaction with litmus paper, and explains it by a decomposition of the tartaric acid by the stronger acids. This change also takes place when Fehling's solution is kept for a length of time in well-stoppered glass bottles.—I. W. WOLL.

Ash of Gidgea acacia (stinking wattle). F. B. GUTHRIE *Agr. Gaz. New South Wales*, 8, 1897, pp. 88, 89; *abs. in Jour. Chem. Soc. [London]*, 74, 1898, No. 425, II, p. 181.—The ash contained lime 90.71, potash 0.6, soda 0.72, phosphoric acid 1.47 per cent. The dry matter of the leaves contained 26.92 per cent of protein.

Composition of the ash of canary seed. T. S. HOFMAN *Landbouw. Tijdschr.*, 5 (1897), pp. 172, 173; *abs. in Jour. Chem. Soc. [London]*, 74, 1898, No. 425, II, p. 180.

A new process for determining starch in the grain of cereals. L. LINDET *Congrès Internat. Chim. Appl.*, 1896, II, pp. 71, 72.—See p. 17.

New extraction apparatus for the determination of fat. LOUISE *Congrès Internat. Chim. Appl.*, 1896, II, pp. 73, 74, fig. 1.

Apparatus for rapid and accurate determination of milk fat. E. M. ARNDT (*Milch Ztg.*, 26, 1897, No. 49, p. 78).—The apparatus is intended to facilitate the determination of fat in milk by the Krug-Hampe method—absorption of milk by

kaolin and anhydrous sodium sulphate, solution of the fat by ethyl ether, evaporating an aliquot part of the solution and weighing the residue.—I. W. WOLL.

Hydrogen generator, C. ASCHMAN (*Chem. Ztg.*, 21 (1897), No. 100, p. 1049, fig. 1).—The essential parts are a filter flask with an exit tube for the gas affixed, and a cylinder of zinc attached to a glass rod, which slides up or down at will through a perforation in the rubber stopper. By this means the zinc may be lowered into the acid in the flask or raised out of it at pleasure.—J. T. ANDERSON.

A burette with a new glass cock (*Chem. Ztg.*, 21 (1897), No. 99, p. 1044, figs. 2).—This burette terminates below in a thickened, stopper-like arrangement, with a lateral opening about half way down. Fitting over this is a ground glass, cone-shaped hood, which is provided with an outlet tube. This hood is movable laterally, and thus its outlet tube may be brought into connection with the aperture of the stopper when the liquid from the burette escapes. A slight turn either way closes the burette.—J. T. ANDERSON.

A new extraction apparatus, H. GÜCKEL (*Ztschr. Angew. Chem.*, 1897, No. 21, p. 683).—This apparatus is recommended for the extraction of both solids and liquids with extraction fluids either lighter or heavier than the material to be extracted. It is made of sufficient size to accommodate 125 gm. of liquid or 150 gm. of solid matter.—J. B. LINDSEY.

A new measuring pipette, O. BLEIER (*Chem. Ztg.*, 21 (1897), No. 98, p. 1038, fig. 1).—The instrument consists of a succession of four bulbs and terminates in a stem so constructed that the bulbs and the stem are of exactly the same volume (say 10 cc.) and have graduation marks accordingly. The stem is subdivided into tenths and hundredths. The pipette is filled by a suction tube at the top, and this tube is provided with a pinch cock, by means of which the outflow of the liquid is regulated. If 10 cc. or less is wanted, fill the stem only—that is, to the first 10 cc. division—and allow the desired quantity to flow out. If more than 10 cc. and not more than 20 cc. is desired, fill the stem and the first bulb—that is, to the second 10 cc. mark—and allow the desired volume to flow out. This form may be used for burettes as well as for pipettes.—J. T. ANDERSON.

Regulations for the construction and calibration of measuring apparatus proposed by the Association of German Chemists (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 375-378).

On normal saccharimeter weights, H. COURTONNE (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 397-400).

Graduation of saccharimeters, A. JOBIN (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 379-390).

Unification of saccharimetric scales, D. SIDERSKY (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 391-396).

Report on agricultural-chemical work, V. STEIN (*Tidsskr. Landökon.*, 16 (1897), No. 5-6, pp. 649-674).—The main results are given of the analyses of 7,114 samples of agricultural products made during 1897, with general discussions. The number of samples of various products analyzed was as follows: Feeding stuffs, 496; artificial fertilizers, 1,265; dairy products, 5,312 (viz. milk, 2,581; butter, 2,695; and cheese, 36); manures, 37; soils and marls, 10; root crops, 16; and sundry products, 8.—F. W. WOLL.

BOTANY.

Notes upon bean and pea tubercles, B. D. HALSTED (*Proc. Soc. Prom. Agr. Sci.*, 1897, pp. 77-81).—The author calls attention to some observations made upon the prevalence of root tubercles under varying conditions of growth of the host plants. In his experimental work at the New Jersey Station he found that in every case there was a decided

increase in yield of beans on soils where several successive crops of beans had been grown over the yield where grown on a soil for the first time. The roots of the plants growing upon old ground were supplied with rather abundant tubercles, with the exception of a portion of a plat which was shaded. Here the tubercles were much less abundant. In the new soil the tubercles were usually almost entirely absent, and during the days of thinning the plants, about twelve days after planting, almost none were observed. At the same time they were very abundant upon the plants in the old ground. This seems to indicate that the root tubercle organisms were present in unusual amount in the old land and in comparatively limited amount in the soil of the new plats.

The study reported on tubercles on the roots of peas was in connection with experiments made to test different kinds of soil treatment on the crop. One portion of the land had received sulphur, a second corrosive sublimate, a third carbonate of lime, and a fourth copper sulphate. All these substances were spread on the soil and spaded in for the second crop of the previous year and consequently had been in the soil for several months before the crop under consideration was sown. The plants were pulled at frequent intervals throughout the growth of the crop and the small proportion of tubercles on the plat where sulphur had been used was noted, the number being less than one-tenth of that where the soil had received no treatment. In the other plats, while there was some difference in the root systems of the plants, there was no decrease in the amount of root tubercles.

Comparisons were made between the tubercles on the roots of beans and peas. The differences in structure and external appearance were so striking as to almost suggest a separate origin. The difference in the root systems of the two plants, however, would probably account for the difference in form of the tubercles.

Some botanical notes on corn, L. H. PAMMEL and R. COMBS (*Iowa Sta. Bul.* 36, pp. 849-855, figs. 8).—Brief notes are given on the origin of corn, and on studies of the flower, fruit, germination, diseases, and enemies of the plant. A few experiments on the germination of corn in the laboratory, greenhouse, and field are reported, in which there was generally a slight loss in the field germination as compared with the others. There are reported three diseases of corn as prevailing in the State, namely, smut, rust, and a bacterial disease.

The flora of Kansas, A. S. HUTCHCOCK (*Industrialist*, 24 (1898), No. 3, pp. 190-198, pls. 4).—Notes are given on the flora of the State. Maps show the distribution of the different species by counties.

A revision of the genus Cordiceps, G. MASSEE (*Rev. Mycol.*, 20 (1898), No. 78, pp. 49-57, pls. 3).—Translated by R. Ferry.

The Rocky Mountain species of Thermopsis, A. NELSON (*Bot. Gaz.*, 25 (1898), No. 4, pp. 275, 276, pl. 1).—*Thermopsis divaricata* and *T. arcuosa* are described as new species.

Studies on surface tension and cohesion, Z. KAMERLING (*Bot. Centbl.*, 73 (1898), Nos. 11, pp. 369-374; 12, pp. 439-444; 13, pp. 465-473).

ZOOLOGY.

The jack rabbits of the United States (*U. S. Dept. Agr., Division of Biological Survey Bul. 8, pp. 81, pls. 6, figs. 2, maps 3*).—Introduction (pp. 1-23).—A popular description is given of the various species of jack rabbits of the United States, their food habits, depredations, distribution, etc. The species noted, found in the United States, are the prairie hare or white-tailed jack rabbit (*Lepus campestris*), which has a range extending over the northern part of the Great Basin and the Great Plains westward from central Iowa, but probably never occurs in such numbers as the black-tailed jack rabbit; the California jack

rabbit (*L. californicus*), which, according to recent investigations is restricted entirely to the region west of the Sierra; the black-tailed rabbit or Texan jack rabbit (*L. texianus*); the black eared jack rabbit or eastern jackass hare (*L. melanotis*), found on the Great Plains from eastern Kansas to the Rocky Mountains and western Texas; Allen's jack rabbit (*L. allenii*) of the deserts of southern Arizona and Sonora; and the Rio Grande jack rabbit (*L. merriami*) of the lower Gulf coast and the Rio Grande region as far as the mouth of Devils River.

Abundance and rapidity of increase (pp. 24-29).—In this chapter it is shown that the breeding habit of the rabbits is such (on an average three per litter and a litter every three months) as to make the animals increase with extreme rapidity, though the evidence on hand does not substantiate the view that the rabbits breed every six weeks in the year. Each species seems to have a regular breeding season and a definite period of rest, for no data are at hand that show that the young are born within the United States during the months of October, November, and December. But it may be said that the period of gestation is about thirty days and that it takes about two months for the young to reach maturity. The practical bearing of these facts is more or less obvious. Drives or hunts for the extermination of rabbits should take place before the beginning of the breeding season. In southern California they should be made in December, January, February, or early in March; in Colorado and Utah, the 1st of February; in Idaho, somewhat later.

Injury to crops and means of protection (pp. 30-35).—The rabbit attacks most garden plants and the bark of orchard trees and seldom ignores alfalfa. Five jack rabbits, it is estimated, consume as much food as one sheep. The method of protection advised is the construction of fences of boards or wire about fields, the use of burlap, and whitewash on single trees.

Methods of destruction (pp. 36-46).—The method of inoculating with chicken cholera or with the so called tintinallody disease and the propagation of the bladder worm and the rabbit scab (*Sarcoptes cuniculi*), rabbit measles (*Cysticereus pisiformis*), and the liver coccidium (*Coccidium oriforme*) as tried in Australia is briefly noted, with the comment that the diseases caused by parasites offer little hope as a means of destruction.

Of the various methods of poisoning, the use of strychnin is thought most worthy of recommendation. Paris green, London purple, lead salts, tartar emetic, barium carbonate, and sulphate of iron and corrosive sublimate, on the other hand, have not been found successful. Phosphorus has been advocated, and means of using it are described.

The bounty methods as followed in Arizona, California, Idaho, Kansas, Nevada, Oregon, Texas, Utah, Washington, and Australia and the amount of money expended are briefly noted.

The natural enemies of the jack rabbits mentioned are the barn owl

(*Strix pratineola*), Audubon's caracara (*Polyborus cheriway*), prairie falcon (*Falco mexicanus*), western red-tailed hawk, western horned owl (*Bubo virginianus subarcticus*), golden eagle (*Aquila chrysaetos*), marsh hawk (*Circus hudsonius*), various coyotes, wolves, and foxes. It is pointed out, however, that birds of prey seldom molest the larger hares.

The epidemics to which they are subject are more or less local and occasionally reduce their numbers materially. A tabular partial list of the epidemics in the West is given.

Rabbit drives and hunts (pp. 47-64).—The formation of rabbit drives and hunts as followed in southern California, Oregon, Utah, Idaho, and Colorado is described. The following table summarizes the results noted:

General summary of 305 jack rabbit drives and hunts in the West.¹

	California, 1875-1897.	Colorado, 1893-1896.	Idaho, 1894-1897.	Oregon, 1894-1895.	Utah, 1894-1896.	Total.
Number of drives	217	312	329	412	235	305
Total number of rabbits killed....	494,634	33,063	34,329	12,202	61,318	635,546
Average number per drive.....	2,389	2,755	1,271	1,016	1,752	2,175
Largest drives	20,000	6,500	5,000	2,000	5,500

¹Including 10 from California and 2 from Idaho for which no figures are available. These drives are not considered in obtaining the averages.

²Both drives and hunts.

³Hunts.

⁴Drives.

The value of the jack rabbit (pp. 65-79).—In this chapter the value of jack rabbits for coursing, for their skins, as game, and for canning, is discussed. It is thought that the canning industry, especially in California, might be very profitable and might make the rabbit pay largely for its own destruction.

The jack rabbits of the United States, T. S. PALMER (*U. S. Dept. Agr., Division of Biological Survey Bul. 8, rev., pp. 88, pls. 6, figs. 3, maps 3*).—Largely a reprint of the first edition. The additions note a special subgenus (*Macrotolagus*), and give further data on the subject of bounties and on rabbit drives as carried on in California and Idaho during 1896 and 1897. An appendix gives an account of an Indian rabbit hunt of the 16th century, and of the modern hunts of the Pueblo Indians, which were very similar in many respects to the rabbit drives of California. In the Fresno rabbit drive of March 21, 1896, at least 20,000 rabbits were corralled and killed.

Some insectivorous mammals, R. ELLIOTT (*Rpt. Ontario Ent. Soc., 1896, pp. 16-21, figs. 4*).—The distribution and usefulness of the little brown bat (*Vespertilio gryphus*), the silvery bat (*Lasionycteris noctiragans*), the brown bat (*Adelonycteris fuscus*), the red bat (*Atalapha noveboracensis*), the hoary bat (*A. cinerea*), the Carolina bat (*Vesperugo carolinensis*), the star-nosed mole (*Condylura cristata*), the shrew mole (*Scalops aquaticus*), the hairy-tailed or brewer's mole (*Scapanus americanus*), the short-tailed shrew (*Blarina brevicauda*), Cooper's shrew (*Sorex cooperi*), broad-nosed shrew (*S. platyrhinus*), the raccoon (*Procyon lotor*), and the skunk (*Mephitis mephitica*) are briefly noted.

Yeast and alcoholic fermentation, J. R. GREEN (*Nature, 57 (1898), No. 1486, pp. 591-594*).—The author summarizes the present information relating to these subjects.

METEOROLOGY.

Solar and terrestrial magnetism in their relations to meteorology, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bureau Bul. 21, pp. 176, charts 39*).—This is a technical explanation of the author's theory that the atmospheric conditions which culminate in the storms traversing the United States are in part due to the direct magnetic action of the sun upon the earth, in which an attempt is made to correlate the observations bearing on this subject into general scientific laws. The general topics treated are the relation between magnetism and meteorology, the determination of the 26.68-day solar magnetic period, analysis of the polar magnetic field along the terrestrial meridians, deflecting forces of the equatorial electromagnetic field, some relations between the terrestrial magnetic field and the meteorological elements, and solar magnetism.

Oklahoma weather and crops for 1897, G. E. MORROW (*Oklahoma Sta. Bul. 30, pp. 12*).—A general account of the soil, meteorological conditions, and agricultural products of Oklahoma, with a record of temperature and rainfall in 1897 as compared with previous years at a number of places in the Territory.

Meteorological observations, J. E. OSTRANDER and A. C. MONAHAN (*Massachusetts Hatch Sta. Mt. Buls. 109, 110, 111, pp. 4 each*).—These bulletins contain notes on the weather and the usual summaries of meteorological observations during January, February, and March, 1898.

Meteorological observations in Denmark, 1896-97 (*Holt's Lommebog Landm., 1898, pp. 88, 89*).

Forstäl meteorological studies, E. HOPPE (*Centbl. Gesam. Forstw. Wien, 24 (1898), No. 4, pp. 147-166*).

WATER—SOILS.

The soils of Tennessee, C. F. VANDERFORD (*Tennessee Sta. Bul., Vol. X, No. 3, pp. IV+31-139, figs. 37, maps 3*).—This is a preliminary report on a systematic survey of the soils of Tennessee, commenced about 6 years ago.

"It is not intended as a complete treatise on the subject. The station has a considerable amount of material which must be reserved for future discussion. This bulletin contains, after a description of the objects and methods of the survey, the physical and chemical analyses and climatological and botanical relations of a number of the most important typical soils of Tennessee. The notes made by the agriculturist on the agricultural treatment of the soil have been pretty fully incorporated for the purpose of interesting the practical farmer.

"The bulletin is accompanied by the preliminary soil map of the State, which was compiled by the station, with the assistance of the United States Geological Survey and the Division of Soils of the United States Department of Agriculture. For the purposes of instruction and further study, this soil map has been put upon a relief map of Tennessee 10 ft. 4 in. long by 2 ft. 10 in. wide, which was prepared by the station in cooperation with the United States Geological Survey. A half-tone plate made from a photograph of this relief-map model is inserted in the bulletin."

Mechanical analyses by M. Whitney, of this Department, and chemical analyses by J. B. McBryde of fifteen samples of soils (with, in some

eases, corresponding subsoil) are reported. The regions and geological formations represented are the Knox dolomite (near Knoxville), the Lenoir limestone of Loudon County, Knox shales of Monroe County, sandstone of Greene County, sandstone and conglomerate overlying coal measures in Grundy County, St. Louis (coral) limestone of Franklin County, the "barrens" of the highlands of Coffee County, blue limestone of the Nashville formation in Maury County, St. Louis (coral) limestone of Robertson County, sandy cretaceous of Benton County, flatwoods (Porters Creek group of Safford), Paris clay of Carroll County, Columbian deposits (Lagrange sands overlaid by orange sands) of Gibson and Fayette counties, and Columbian deposits (the loess, bluff loam of Safford) of Dyer County.

The agricultural value and the best methods of management of the different soils are very fully discussed, especial attention being given to the necessity of protection against washing and the maintenance of a sufficient supply of humus in the soil.

A brief account is given of an experiment on four plats of soil on the station grounds with barnyard manure and different mixtures of commercial fertilizers. The crops grown were corn followed by soy beans and cowpeas. Chemical analyses, including the determination of phosphoric acid and potash soluble in 1 per cent citric acid, were made at the beginning and the end of the experiment. The results indicate that the barnyard manure was not only very effective as a direct fertilizer, but was more active than the other fertilizers in rendering the phosphoric acid and potash of the soil assimilable.

The author concludes that on four-fifths of the farm lands of Tennessee "the use of commercial fertilizers, or fertilizer materials, must come more and more into practice. The making, saving, and use of farm manures, the growing of crops specially planted for the purpose of adding to the humus supply, the careful husbanding of all materials which may be incorporated into the soil to aid in chemical, physical, and biological changes which must be actively persistent if fertility is to be maintained, are acknowledged necessary things."

Soil moisture, J. B. WEEMS and J. J. EDGERTON (*Iowa Sta. Bul.* 36, pp. 825-848).—This is an account of a continuation during 1896 of work commenced in 1895:¹

"In addition to the effect produced upon the moisture present in the soil by certain crops, attention was given to the influence of spring plowing, fall plowing, and fall plowing with subsoiling, upon the amount of moisture in connection with growing crops. The soil upon which the experiments were made was of as uniform a nature as possible, in order to reduce the influence of the difference in the mechanical condition to a minimum. The weight of the soil varied according to the depth, and the weight for each cubic foot is given in the following table: First cubic foot, 70.23 lbs.; second cubic foot, 98.38 lbs.; third cubic foot, 94.78 lbs.; fourth cubic foot, 103.60 lbs. The above weights are for the air-dried soil, which contained moisture as follows: 2.88 per cent for the first, 2.84 per cent for the second, 1.80 per cent for the third, and 1.30 per cent for the fourth cubic foot."

¹ Iowa Sta. Bul. 32 (E. S. R., 8, p. 477).

Mechanical analyses¹ of the soil are given in the following table:

Mechanical analyses of the soil at different depths.

	First foot.	Second foot.	Third foot.	Fourth foot.

¹ Made by I. J. Mead.

The amount of moisture found in the plats July 10 may be taken as representing the condition of the soil during the dry period. The averages for this date on some of the plats are given as follows: Clover plat: Spring plowed, 12.52 per cent; fall plowed, subsoiled, 11.39 per cent; fall plowed, not subsoiled, 9.38 per cent. Oat plat (to a depth of 3 ft.): Spring plowed, 10.86 per cent; fall plowed, subsoiled, 10.87 per cent; fall plowed, not subsoiled, 8.50 per cent. Barley plat: Spring plowed, 11.26 per cent; fall plowed, subsoiled, 10.36 per cent; fall plowed, not subsoiled, 8.32 per cent. Beet plat: Spring plowed, 15.31 per cent; fall plowed, subsoiled, 18.05 per cent; fall plowed, not subsoiled, 12.69 per cent. Corn plat: Spring plowed, 15.51 per cent; fall plowed, subsoiled, 16.29 per cent; fall plowed, not subsoiled, 16.23 per cent.

"The amount of moisture present in the pasture was uniform for the season when compared with the changes which take place in many of the other plats. This characteristic of the blue-grass plat compares favorably with the results of 1895."

Mechanical analyses and water content of Wyoming soils, C. B. RIDGAWAY (*Wyoming Sta. Bul. 35, pp. 159-188, pls. 5, charts 3*).—This is a continuation and extension of work reported in Bulletin 6 of this station (*E. S. R., 4, p. 23*).

The general characteristics of what were considered typical Wyoming soils at the station and substations are described, with notes on natural vegetation and maximum yields of different farm crops. Mechanical analyses of three samples of soil with corresponding subsoil collected at Wheatland, Sundance, Sheridan, Lander, and Laramie are reported. Chemical analyses of soils and subsoils from each of the above farms are republished from the bulletin above referred to, and a record is given of daily determinations of moisture during the period from April to September on prairie sod and on cultivated (plowed and harrowed) and subsoiled plats (the last two being seeded to oats) on the station farm at Laramie. For purposes of comparison, observations on rainfall and evaporation are also reported.

The average results of the mechanical analyses are shown by the following table:

Mechanical analyses of Wyoming soils.

	Wheatland.	Sundance.	Sheridan.	Lander.	Laramie.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Gravel	1.05	0.17	0.22	0.21	5.78
Coarse sand	1.85	.15	.56	.21	3.79
Medium sand	8.60	.80	10.56	.67	7.77
Fine sand	15.09	1.93	34.33	3.44	5.90
Very fine sand	40.16	51.49	19.03	54.74	29.00
Silt	6.18	20.93	5.73	16.66	5.39
Fine silt	4.33	3.69	1.90	4.43	2.92
Clay	15.19	13.09	20.28	13.36	22.98

The results of the mechanical analyses as well as of the moisture determination are shown graphically. From the latter it was found "that the amount of moisture in samples of the same soil, taken the same

day and not more than 12 in. apart, varied from 2 to 4 per cent." The maximum water content was found two or three days after a heavy fall of rain, "which is doubtless caused by seepage of water from a higher level." The minimum amount of water was about 5 per cent, and this was observed at the end of June. At the end of the season the prairie sod contained 6 per cent of moisture, the cultivated soil $6\frac{1}{2}$ per cent, and the subsoiled land $8\frac{1}{2}$ per cent.

The electrical method of moisture determination in soils, F. D. GARDNER (*U. S. Dept. Agr., Division of Soils Bul. 12, pp. 21, fig. 1, charts 6*).—As a result of field trials of the electrical method of moisture determination in soils described in a previous bulletin,¹ "some slight modifications in the apparatus and in the method of its operation which will greatly facilitate the taking of the observations and the calculations of the results" are suggested. These include modifications of the electrodes to insure more perfect insulation and to adapt them to "very light sandy soils having a low salt content and small water capacity," the use of lead-covered underground wires for connecting the electrodes, and precautions regarding the cleaning of the different parts of the instrument. The standardization of the electrodes by means of direct determinations of moisture in soil is explained, and observations on the effect of the distance between electrodes on the resistance are reported.

"[During the year] fourteen sets of the instruments were placed in the hands of farmers located in widely different sections of the country and on markedly different types of soil. Observations were made daily of the electrical resistance of the soil at the depths of 1 to 3, 3 to 6, 9 to 12, and 21 to 24 in., except in a few instances where the 1 to 3 in. depth was omitted on account of the very loose and dry condition of the surface soil. The observations were taken during the crop season of the particular locality and extended over periods of from three to four and one-half months, the average time being approximately four months for each observer."

The results of these observations are reported in charts and tables.

The bulletin also contains a note by T. H. Means on a modification of the electrical method of determining the soluble salt content of soils.²

"It has been found that this method is not applicable to soils containing a large amount of soluble salt, as with the alkali soils of the West, for the salt added materially changes the amount of dissociated salt in the soil. This led to a careful review of the work which had previously been done, and it appears probable that the apparent influence of the texture of the soil . . . is largely due to the effect of the added salt upon the dissociated salt content of the soil. Correcting for this, the influence of the texture of a soil upon the resistance of a solution seems to be a constant which does not vary with the nature of the soil, provided the soil is thoroughly saturated with water. This factor has not been established with great accuracy as yet, but it appears to be approximately 0.51 or 0.56."

The chemical composition of Utah soils, J. A. WIDTSOE (*Utah Sta. Bul. 52, pp. 37-84*).—This is a report of the first of a proposed series of systematic studies of the soils of Utah, and is devoted to the soils of Cache and Sanpete counties. It includes a general discussion of the

¹U. S. Dept. Agr., Division of Soils Bul. 6 (E. S. R., 9, p. 535).

²U. S. Dept. Agr., Division of Soils Bul. 8 (E. S. R., 9, p. 535).

relation of the plant to the soil, suggestions regarding the maintenance and increase of fertility of Utah soils, descriptions of the Cache and Sanpete Valleys, and chemical analyses of 37 samples of soils from Cache County and 18 samples from Sanpete County. The averages of these analyses are given in the following table:

Composition of soils from Cache and Sanpete counties, Utah.

	Average of Cache County soils.	Average of Sanpete County soils.

Water at 15° C.	2.370	1.830

"The general nature of Cache Valley soils is that of a moderately clayey loam. The soils on the hillsides, which have been influenced by the seasonal wash from the mountains, contain most clay. The soils along the middle of the valley are more sandy, although occasional tracts of clay soils occur.

"Cache Valley soils do not differ much in composition from the majority of the soils of the arid part of America. They are abundantly supplied with all the essential plant foods, and, with proper tillage, will 'last' for an indefinite period. Phosphoric acid is present in least abundance. . . .

"The general nature of Sanpete Valley soils is that of a rather clayey soil mixed with an extraordinarily large amount of lime. The excess of lime obscures the properties of the clay.

"In composition the soils of Sanpete Valley differ from recorded analyses of soils from other portions of the Great Basin in that they contain more lime. Otherwise they are not strikingly different. They are extremely fertile soils that 'last' for an indefinite period. As in Cache Valley soils, the phosphoric acid is least abundant."

Drinking water, N. E. WILSON (*Nevada Sta. Bul. 34, pp. 16*).—Tables give analyses, with reference to sanitary condition, of 79 samples of drinking water from different parts of the State, accompanied by explanation of terms used in discussing water analysis and remarks on the dissemination of disease through drinking water.

On the relation between geological formations and the composition of the soil, A. BERNARD (*2. Congrès Internat. Chim. Appl., 1896, II, pp. 256-266, dgms. 6*).—The soils of Saône-et-Loire are arranged on the basis of their chemical and physical analyses in 6 classes, and the relationship between physical constitution and chemical composition is plotted in diagrams.

(1) The granitic soils, represented by 90 analyses, are generally poor in phosphoric acid, and destitute of lime.

(2) Clay soils, represented by 22 analyses, are compact and tenacious, poor in phosphoric acid, and rich in potash.

(3) The Lias soils in the 3 stages of transformation, represented by 75 analyses, are remarkably rich in phosphoric acid and potash.

(4) The calcareous soils, represented by 53 analyses, are very fertile and less tenacious than the preceding.

(5) Soils of the Oxford formation, represented by 90 analyses, are strong, rich, clayey calcareous soils.

(6) Ferruginous clays and sands, represented by 230 analyses, are very poor soils, extremely deficient in lime and phosphoric acid.

On the determination of the available constituents of the soil, C. V. GAROLA (*Congres Internat. Chim. Appl., 1896, II, pp. 143-150*).—Determinations of the potash and phosphoric acid in fertilized and unfertilized soils soluble in strong nitric acid (100 cc. of nitric acid 1.4 sp. gr. and 50 cc. water to each 50 gm. soil), 2 per cent citric acid, and nitric acid of the same acidity (0.013 per cent of hydrogen) as the average found by Dyer in the juice of plant roots.¹

The relation between the amounts of phosphoric acid soluble in these different reagents and the productiveness of the soil, as well as the influence of applications of different phosphates upon the amount and availability of the phosphoric acid of the soil, are discussed.

FERTILIZERS.

On Wiborgh phosphate, its manufacture and agricultural value, L. F. NILSON (*K. Landt. Akad. Handl. Tidskr., 37 (1898), No. 1, pp. 49-63*).—This new fertilizer, which promises to become of the highest agricultural importance, is manufactured by a process invented by J. Wiborgh, of the Technological Institute of Stockholm (Sweden). Briefly stated, the phosphate is prepared by fusing a thorough mixture of finely comminuted mineral phosphates, like apatite, and feldspar, with powdered sodium carbonate at a temperature of from 400 to 1,000 °C. The reaction which takes place has been studied in a series of experiments by the author, and is expressed by the following formulas:

The composition of the resulting product is shown by the following analysis: Phosphoric acid 27.01, silica 9.99, sulphuric acid (SO₃) 0.27, potassium oxid 1.54, sodium oxid 14.69, calcium oxid 38.12, magnesium oxid 2.88, iron and aluminum oxids 4.5, and fluorin (and errors of analysis) 1 per cent.

The Wiborgh phosphate may be easily ground to an exceedingly fine powder of limonite color. It dissolves in hydrochloric acid without residue, and is but slightly soluble in water even at higher temperatures. It is easily soluble in ammonium citrate solution, its percentage solubility being on the average 95 per cent, having been determined by Scandinavian and German chemists at from 93 to 96 per cent. The citrate solubility of the phosphate increases with the proportion of sodium carbonate used in fusing the apatite, up to the theoretical amount required for the reaction to take place, which is about 30 parts of sodium carbonate per 100 parts of apatite, the latter containing about 17 parts of feldspar.

¹ Jour. Chem. Soc. [London], 1891, p. 115; Chem. News, 69 (1894), p. 113 (E. S. R., 5, p. 4013).

Relation between amount of sodium carbonate used in fusion and the citrate solubility of the product.

	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Sodium carbonate added	20	22.5	25	27.5	30	32.5
Citrate solubility	67	70.0	74	87.0	93	93.0

The presence of feldspar in fusing apatite with sodium carbonate is important, since a high citrate solubility can not otherwise be obtained. Fusions with and without feldspar gave the following results: Pure apatite with 2 parts sodium carbonate, 37 per cent citrate solubility; with 3 parts sodium carbonate, 72 per cent; 83 parts pure apatite and 17 parts pure feldspar with 20 parts sodium carbonate, 64 per cent; 83 parts pure apatite and 17 parts pure feldspar with 30 parts sodium carbonate, 94 per cent.

The raw material for the manufacture of the Wiborgh phosphate is found in enormous quantities in Sweden in the Gellivare iron ore, from which the magnetic iron has been separated, leaving a finely divided refuse product of silicic apatite; four-fifths of the latter consists of pure calcium phosphate and one-fifth mainly of feldspar, with some quartz, mica, and hematite. The phosphoric acid content of the raw material reaches 35 per cent.

Fertilizer experiments.—Preliminary experiments made with Wiborgh phosphate during 1896 indicated that the phosphoric acid contained therein possessed a greater value than Thomas slag, approaching that of the water-soluble phosphoric acid in superphosphates. The experiments were continued on a somewhat larger scale in 1897 with oats grown in sandy soil and with peas and sugar beets grown in marsh soil. The Thomas phosphate used had a citrate solubility of 88 per cent. The glass cylinders used were 50 cm. high, 25 cm. in diameter, with a surface of 0.05 sq. meter. They were filled with 25 kg. sand in the oat experiments and with 15.5 kg. of marsh soil in the pea experiments. In case of the oats a basal fertilizer of 300 kg. potash (sulphate), 100 kg. nitrogen (nitrate), 2,000 kg. powdered marble, 200 kg. salt, and 200 kg. land plaster was applied; in case of the peas, 300 kg. potash (sulphate) and 200 kg. salt. The results obtained with the first two crops are summarized in the following table:

Pot experiments with Wiborgh and other phosphates on oats and peas.

	Rate of application of citrate-soluble or water-soluble phosphoric acid per hectare.										No phosphate.	
	Wiborgh phosphate.				Thomas phosphate.				Superphosphate.			
	50 kg.	75 kg.	100 kg.	150 kg.	50 kg.	75 kg.	100 kg.	150 kg.	50 kg.	75 kg.		100 kg.
Yield of oats:												
Grain (grams)	27.4	31.2	32.8	37.9	26.3	31.8	33.9	36.6	19.6	26.6	31.3	8.5
Straw (grams)	33.1	39.6	43.2	46.6	32.3	39.2	43.0	46.9	21.9	33.5	40.0	10.2
Yield of peas:												
Peas (grams)	22.8	37.4	47.1	66.4	22.4	36.3	46.8	66.6	23.0	36.4	48.1	4.3
Vines (grams)	37.4	52.5	60.7	79.7	43.0	57.0	64.6	83.3	38.9	53.3	66.5	11.8

The experiments with sugar beets were made in glass cylinders 75 cm. high and 26 cm. diameter, cement-lined boxes of 1 cubic meter content, and zinc boxes with a surface of 0.3 square meter, the latter being placed in the ground. There were six trials in the cylinders and cement-lined boxes and five in the zinc boxes. In all cases the marsh soil used in the trials received sulphate of potash at the rate of 267 lbs. and sodium nitrate at the rate of 22 lbs. per acre. The following table gives the average results of the experiments:

Experiments with Wiborgh and other phosphates on sugar beets.

	Rate of application of citrate-soluble or water-soluble phosphoric acid per hectare.												
	Wiborgh phosphate.				Thomas phosphate.				Superphosphate.				
	50 kg.	75 kg.	100 kg.	150 kg.	50 kg.	75 kg.	100 kg.	150 kg.	50 kg.	75 kg.	100 kg.		
In glass cylinders:													
Yield of beets (grams)	880	1,770	2,580	3,200	985	1,850	2,680	3,430	995	1,356		2,530	
Sugar content (per cent)	16.38	17.16	17.23	18.15	16.00	16.00	16.92	17.46	16.62	16.00		17.08	
In cement-lined boxes:													
Yield of beets (grams)	4,340	5,210	6,650	7,610	5,150	6,120	6,180	7,600	3,720	5,520		6,140	
Sugar content (per cent)	15.90	15.23	15.00	16.08	14.77	15.23	15.00	15.84	15.54	14.46		15.38	
In zinc boxes:													
Yield of beets (grams)	2,672	2,998	3,120	3,475	2,678	3,066	3,110	3,582	2,815	3,238		3,000	
Sugar content (per cent)	15.01	15.96	15.94	16.21	15.15	15.92	15.80	16.08	13.82	14.89		16.19	

The soil used in the first two series of experiments was extremely deficient in available phosphoric acid, and in check experiments without applications of phosphate no crop was produced. The check experiments in the third series gave an average yield of 1,078 gm. of beets, with 13.27 per cent or 143.1 gm. of sugar. The results of the experiments show that Wiborgh phosphate is at least equal to Thomas phosphate or superphosphate for the culture of sugar beets on marsh soils.—F. W. WOLL.

The assimilation of nitric acid as well as the action of different nitrates, W. SCHNEIDEWIND (*Jour. Landw.*, 46 (1898), No. 1, pp. 1-8).—In experiments with sugar beets in 1894 and 1895, it was found that nitrate of soda acted more quickly than nitrate of potash, a fact which was attributed to the greater diffusibility of the sodium salt. Further experiments with different nitrates were made with oats grown on artificial soil (sand with 2½ per cent of peat) in pots in 1896. The nitrogen was applied in the form of sodium, potassium, calcium, and magnesium nitrates. In addition to the nitrates, calcium carbonate, potassium phosphate, potassium sulphate, potassium chlorid, and magnesium sulphate were applied. The yield and analyses of the crop are tabulated. The largest yield of grain and the smallest yield of straw was obtained from the pot receiving magnesium nitrate. This is attributed to the

physiological rôle which magnesium plays in the formation of seeds. The opposite result was obtained with potassium nitrate. The amounts of nitrogen, phosphoric acid, and chlorine in the crop were practically the same in each experiment. The relative proportions of potash and soda vary to a considerable extent with the relative amounts applied to the soil. Thus, in the experiment with sodium nitrate the crop took up 4.32 gm. of potash and 9.17 gm. of sodium. In the experiment with potassium nitrate, the crop contained 9.08 gm. of potash and 5.39 gm. of soda. The amount of lime which the plant contained was not appreciably increased by the application of calcium nitrate. The proportion of magnesium in the grain, however, was decidedly increased by the application of magnesium nitrate to the soil.

Bacteria obtained from manure and their physiological rôle in the decomposition of manure, S. A. SEWERIN (*Centbl. Bakt. u. Par., 2. Abt., 3 (1897), Nos. 23-24, pp. 628-633; 25-26, pp. 706-718, figs. 2*).—A number of organisms isolated from manure are described and culture experiments with them are reported. The action of some of these organisms was compared with that of *Bacillus pyocyaneus* on mixtures of horse manure and urine. The decomposition of the manure was measured by the carbon dioxide produced. The results indicate that the organisms were generally effective in reducing the organic matter only when urine was present, but that when the activity of the organisms was once started they not only reduced the organic matter in the urine, but also attacked that of the solid excrement.

Green manuring and the value of clovers and cowpeas in maintaining soil fertility, H. J. WATERS (*Missouri Sta. Rpt. 1897, pp. 26-33, figs. 2*).—Reprinted from Bulletin 34 of the station (E. S. R., 8, p. 969).

The economic value of farm manures, H. J. WATERS (*Missouri Sta. Rpt. 1897, pp. 20-25*).—Reprinted from Bulletin 34 of the station (E. S. R., 8, p. 969).

The agricultural value of Thomas slag, CLUSS (*2. Congrès Internat. Chim. Appl., 1896, II, pp. 151-154*).—The author quotes experiments at Halle to prove that the citrate solubility is a reliable indication of the fertilizing value of the phosphoric acid in Thomas slag; that the phosphoric acid insoluble in the citrate solution is practically worthless for fertilizing purposes, and that fusing the slag with silica increases citrate solubility and fertilizing value.

Study on natural phosphates, H. LASNE (*2. Congrès Internat. Chim. Appl., 1896, III, pp. 24-50*).—This article discusses the origin, deposits, composition, and exploitation of the principal phosphates of the world, which are grouped in two classes, (1) sedimentary fluorophosphates and (2) phosphates of animal origin. The method of analysis used in studying the composition of the different phosphates is given in detail.

Study on the use of phosphatic fertilizers on the subcretaceous soils of Puisaye, POTIER (*Ann. Sci. Agron., 1897, II, Nos. 1, pp. 136-160; 2, pp. 161-174*).

The phosphates of Algeria, J. DUGAST (*Rev. Gén. Sci. Pures et Appl., 8 (1897), No. 19, pp. 769-783, figs. 11*).—The origin, nature, extent, exploitation, and agricultural value of these phosphates are very fully treated.

Phosphatic slags, H. JOULIE (*2. Congrès Internat. Chim. Appl., 1896, II, pp. 167-173*).—Gives analyses of different samples and their solubility in ammonium oxalate, acetic acid, and ammoniacal ammonium citrate, according to Millot, with a brief dis-

discussion of assimilability, price, and adulteration. The action of ammonium oxalate was less vigorous than that of the acetic acid and citrate, depending upon the amount of calcium silicate present.

Report of analyses of commercial fertilizers for the fall of 1897, L. L. VAN SLYKE (*New York State Sta. Bul.* 131, pp. 503-511).—The results of analyses of 248 different brands of fertilizers are reported, and the composition and quality of the fertilizers offered for sale in the State during the fall of 1897 are discussed. Of the 248 brands examined 172 were complete fertilizers. In these the nitrogen varied from 0.58 to 1.89 per cent, averaging 1.69 per cent; the available phosphoric acid varied from 3.81 to 12.78 per cent, averaging 9.22 per cent; the potash varied from 0.58 to 16.52 per cent, averaging 3.92 per cent. The average amounts of nitrogen, available phosphoric acid, and potash exceeded the guaranteed average by 0.16, 0.7, and 0.18 per cent, respectively.

Analyses of commercial fertilizers, B. W. KILGORE ET AL. (*Mississippi Sta. Spec. Bul.* 17, pp. 23).—A report of analyses and valuations of 102 samples of fertilizing materials collected in Mississippi during the latter part of December, 1897, and in January, February, and March, 1898.

Results of the fertilizer control in the Baltic Provinces, 1896-97, G. TUOMS (*Die Ergebnisse der Dünger-Kontrolle, 1896-97. Riga, 1897, pp. 90*).—This is a reprint from *Baltischen Wochenschrift für Landwirtschaft, 1897, No. 48*, and contains reports on the importation of fertilizers into the Baltic Provinces during 1896, an account of the inspection work of the Riga Station, and a general review of literature on the quality and use of different fertilizing materials, with special applications to local conditions.

The inspection of fertilizers in 1897, F. W. MORSE (*New Hampshire Sta. Bul.* 49, pp. 18).—This is an account of the inspection of fertilizers in New Hampshire in 1897 by the Experiment Station in cooperation with the State Board of Agriculture, and includes the public statutes of New Hampshire relating to fertilizers; trade values of fertilizing ingredients for 1897; tabulated analyses of 112 different brands of mixed fertilizers and 8 samples of fertilizing chemicals, including muriate of potash, sulphate of ammonia, bone, dissolved boneblack, and tankage; a brief discussion of the price and quality of fertilizers sold in the State, and suggestions regarding the selection of fertilizers. The prices of fertilizers were lower during 1897 than they have ever been before, and the composition of mixed fertilizers generally exceeded the minimum guaranty, very few samples showing deficits in composition.

Report on the enforcement of the fertilizer control law, H. J. WATERS (*Missouri Sta. Rpt. 1897, pp. 1-9*).—Reprinted from Bulletin 31 of the station (E. S. R., 8, p. 970).

On the prevention of fraud in fertilizers and feeding stuffs, D. MOLINARI (*2 Congrès Internat. Chim. Appl., 1896, II, pp. 178-181*).

The enforcement of laws relative to repression of fraud in fertilizers, E. SILZE (*2. Congrès Internat. Chim. Appl., 1896, II, pp. 185-189*).

FIELD CROPS.

Cooperative experiments in agriculture, C. A. ZAVITZ (*Ontario Agr. and Expt. Union Rpt. 1897, pp. 13-10*).—This is a report of 18 cooperative experiments with fertilizers, fodder crops, roots, grains, grasses, and clovers carried on by 2,835 experimenters throughout Ontario in 1897. The experiments conducted at the Ontario Agricultural College (E. S. R., 9, p. 440) form the basis of the system, and varieties which have there shown themselves to be in the lead are given a further trial in cooperative tests. The results are reported in tabular form and briefly discussed.

The summary of the results of the fertilizer experiments shows that the largest average yield was produced with the use of a complete fertilizer with oats, a potassic fertilizer with corn, and a nitrogenous fertilizer with mangel-wurzels. No one variety of corn showed itself well adapted to all parts of Ontario. Cloud Early Dent has held first place in yield of whole crop for four years in succession. Grass peas were more productive and were better relished by stock when fed green than tares or crimson clover. For the production of green fodder, a mixture of 1½ bu. of oats and 1 bu. of peas and tares is recommended. This being the first year that experiments with grasses and clovers were carried on the comparative results are limited. The three varieties of buckwheat tested, Japanese, Silver Hull, and Common Gray, mentioned in the order of their productiveness, gave an average of 28 bu. per acre. Herison Bearded Spring Wheat has given the largest yield of grain per acre for four years, but this season it stood second, the Wild Goose variety giving the largest average yield of four varieties under trial in 1897. The Wild Goose Spring Wheat is considered inferior in quality. Mandscheuri Barley has given the best average yield of grain in the comparative tests and the 6-rowed varieties proved more productive than the 2-rowed and hullless varieties for six years in succession. In the comparative tests of oats during six successive years, the Siberian variety stood first in productiveness for four years but the Oderbrucker gave the largest average yield in 1896 and 1897. Among four leading varieties of peas Early Briton for two years in succession produced the largest yields. In cooperative tests of potatoes Empire State gave the best average yields for three years but fell back to third place this season. Dawson Golden Chaff Winter Wheat stood highest in productiveness for five years and was the most popular variety with the experimenters.

Experiments with cotton, J. F. DUGGAR (*Alabama College Sta. Bul. 89, pp. 24*).—This work comprises variety, fertilizer, and seed tests, and culture and distance experiments. Work along similar lines has been formerly reported (*E. S. R.*, 9, p. 40). Of 17 well-known varieties and 15 cross bred varieties originated at the station, Texas Oak, Griffin, Hawkins, Deering, Mell Cross No. 15, Jones Reimproved, Duncan, Hutchinson, Peterkin, Truitt, and Whatley led in the increased yield of lint cotton over the check variety (Peerless). A classification of lint of the varieties grown in these experiments is given.

The results from seed of the same original stock grown for one year in different latitudes were so nearly alike that no effect could be ascribed to latitude or climate. The average results of three experiments in two years with fresh, 1-year old, and 2-year old cotton seed showed but a slight difference. The names of parties from whom cotton seed may be obtained are given.

A plat "laid by" July 26 yielded 25 lbs. of seed cotton per acre more than the average of two plats "laid by" two weeks earlier. The

increase is considered sufficient to pay for the extra cultivation. Subsoiling in January was quite beneficial to the first crop but it afforded no increase the second year.

Rows 3 ft. 1 in. apart gave practically the same yield whether the plants were 12, 18, or 24 in. apart in the row, but when the distance was increased to 30 in. the yield was noticeably reduced.

Applying 640 lbs. of slaked lime per acre broadcast showed no increase in the cotton crop that year, but the next year cotton, following cowpeas which were turned under in the spring, yielded more on the plat limed the year before than on the plat which had not been limed. A mixture of barnyard manure, cotton-seed meal, and acid phosphate was more effective when applied without composting than when composted about 1 month before using. Bedding on all the fertilizer gave better results than reserving one-fourth and applying it in the drill at planting time. An application of 150 lbs. of cotton-seed meal per acre resulted in a larger yield of seed cotton than the application of 316 lbs. of cotton seed or 70.5 lbs. nitrate of soda, these quantities furnishing equal amounts of nitrogen. Acid phosphate proved to be more effective than Florida soft phosphate except when the crude phosphate was employed in compost. A mixture of these two phosphatic fertilizers was less effective than an equal weight of acid phosphate and more effective than the same amount of Florida soft phosphate. Cotton-seed meal, acid phosphate, and kainit were applied singly and in different combinations at the rate of 200, 240, and 200 lbs. per acre respectively. The use of kainit alone was most profitable, and cotton seed meal alone stood second. Acid phosphate applied singly gave no increase in yield. The apparent average increase in yield of seed cotton per acre due to the different fertilizers applied to plats which had received no fertilizer, or which received kainit or acid phosphate or both, was 116 lbs. for cotton-seed meal and 151 for kainit, and a decrease of 103 lbs. for acid phosphate.

Topping cotton did not prove profitable.

Red rice, W. R. DODSON (*Louisiana Stas. Bul. 50, 2. ser., pp. 208-226, pl. 1*).—A description of red rice is given and the results of experiments conducted to ascertain its origin are discussed. The flower of the rice plant and the natural provision for preserving the seed of red rice are described. The author points out the disadvantages of red rice in rice fields, considers its botanical relations, and makes suggestions how to prevent its occurrence. A test of 17 varieties of rice is reported. The experiments led to the following conclusions:

“Red rice is a different variety from the white rice. White rice will not produce red seeds when the seeds have been exposed to the weather all winter, as is commonly believed by planters. The two varieties will cross, producing hybrids, and these hybrids tend to revert to one of the parent forms, the red rice being a little stronger.

“Red rice, being dependent upon self-preservation, is hardier than the white rice

and also has a special device for preventing the seed from reaching the ground in early fall.

"The proper methods to be adopted are to use clean seed and prevent red rice from seeding after the general harvest."

Sugar-beet investigations in Wisconsin during 1897, F. W. WOLL (*Wisconsin Sta. Bul. 61, pp. 101, figs. 5*).—The work reported consisted of cooperative culture experiments made by farmers in the counties adapted to agriculture; culture tests at one or more substations in a number of counties, at each of which one-half acre of beets were grown under the direction of the station to ascertain the cost of production; a variety test; and a fertilizer experiment with sugar beets on marshy soil at the station farm. The results are tabulated and the analytical work is described. The season was not very favorable for the growth of sugar beets.

For the cooperative experiments 13,766 one-fourth pound packages of seed were sent out with complete directions for sowing, cultivating, etc. Analyses were made of 1,663 samples of beets from 68 counties, showing an average of 12.67 per cent of sugar in the juice with 74.1 as the average coefficient of purity. The average yield of beets per acre in these experiments is estimated at 12.8 tons. The richest beets were grown on the drift soils of the State. The counties located in the driftless section or sandstone section produced beets of the lowest average richness. The author states that "the sugar beet, in order to reach its highest development, requires soils rich in lime, and with us preferably such as are produced by glacial drift overlying limestone formations or produced by the decomposition of the Keweenawan or copper-bearing series (shale, conglomerate porphyry, etc.), in the extreme northwest of the State."

The relative value of beets of different degrees of purity, the importance of proper culture, and the influence of the soil are discussed. It was found that white beets are richer in sugar and have a higher coefficient of purity than red beets. Proper culture was found to be of greater importance than the use of any particular kind of standard seed. It was observed that in general beets grown after cereals were of good quality, and that beets following summer fallow were exceptionally high in sugar content and purity. A number of rotations are suggested.

The average cost of growing an acre of beets at 28 substations was \$28.73 including all items from plowing the soil to storing the beets, except the cost of the seed and the rent of the land. The average yield obtained at 27 substations was 29,850 lbs. of beets per acre. Analyses were made of samples taken at the time the beets were harvested and about 1 month earlier. Forty-seven early samples from 36 substations averaged 13.49 per cent of sugar in the juice, with a purity of 80.6; while 46 samples taken at the time of harvesting averaged 15.22 per cent of sugar in the juice with a purity of 80.2.

At the station farm a 3-acre field was plowed 6 in. deep on May 7,

and the western half of the field was plowed a second time 10 in. deep and four-fifths of it subsoiled to 16 in. on May 20. The field was not particularly adapted to the sugar-beet crop, and on part of the field the crop failed. Thirteen different varieties were grown. Kleinwanzleben (seed imported from Germany) produced the highest yield on the unsubsoiled half of the field and Agnew Kleinwanzleben (a variety grown in California) on the largely subsoiled half. On the unsubsoiled half the average yield was 18,013 lbs. per acre, with an average of 13.22 per cent of sugar in the beet, while on the other half the average yield was 18,472 lbs. per acre, with an average of 14.18 per cent of sugar in the beet. The cost of growing an acre of beets in these experiments, not including the cost of seed and rent of land, was found to be \$32.15.

Eight varieties were grown from high-grade seed. The sugar content in the juice ranged from 13.84 per cent in the Demesmay variety to 17.85 per cent in the High Grade Commercial Kleinwanzleben. The purity of the latter variety was the lowest, being 79.5 while that of Vilmorin La Plus Riche was highest, being 86.1. The average yield of beets per acre for all varieties was 28,103 lbs. with an average of 15.04 per cent of sugar in the beet.

Fertilizer experiments with beets were conducted on a tile drained marshy soil, and the effect of different kinds and combinations of fertilizers was compared. The average yield of beets per acre on the marshy soil was 11,774 lbs. The best results were obtained from the plat to which a mixture of double carbonate of potash and magnesia, bone superphosphate, and nitrate of soda had been applied. As a rule the beets grown on the unmanured marshy plats were not so good in quality as those grown on the 3 acre field described above.

The sugar beet in Pennsylvania, H. P. ARMSBY (*Pennsylvania Sta. Bul. 40, pp. 23*).—This bulletin contains a report on cooperative culture experiments with the sugar beet in different counties in 1897 with notes and suggestions of a general character on the beet crop, the requirements for manufacturing beet sugar, and the adaptability of the industry to the State. The results of the experiments and the meteorological data for the season are given in tables.

Of the 69 samples reported upon 55 had a sugar content of over 12 per cent in the beet and 35 a coefficient of purity above 80; 32 showed a sugar content of over 12 per cent and a coefficient of purity above 80. The average size of the beets and the yield were rather small.

Report on the results obtained with sugar cane on the experimental fields at Dodds' Reformatory, 1896, J. R. BOVELL and J. P. D'ALBUQUERQUE (*Rpt. Expt. Fields Dodds' Reform. [Barbados], 1897, pp. 30*).—Work in this line has been formerly reported (*E. S. R., 8, p. 394*). The amount and composition of the rainfall are given in a table, and the results of experiments with manures and varieties of cane and seedling cane are reported.

Nitrogenous and phosphatic fertilizers were applied at different times and in different forms and proportions. Potash was used in the form

of sulphate and applied in varying amounts and at different times. The canes were planted on twentieth-acre plats in December, 1894, and harvested in April, 1896. The application of sulphate of ammonia, supplying 60 lbs. of nitrogen per acre, in connection with mineral manures, gave the most advantageous returns in the nitrogen series of experiments. Dried blood, up to the equivalent of 60 lbs. of nitrogen per acre, was most beneficial when applied during the earlier stages of cane growth. Sulphate of ammonia was found preferable to nitrate of soda as a source of nitrogen. The application of finely ground basic slag, furnishing 100 lbs. of phosphate per acre, applied during the early stages of cane growth, increased the yield of sugar, while the application of superphosphate caused a decrease in the yield. In the potash experiments the use of the sulphate, at the rate of 60 lbs. of potash per acre, produced the best results, and when applied in connection with nitrogen and phosphates largely increased the yield of cane and sugar.

Among the different varieties Caledonia Queen, Queensland Creole, and Seedling 7 yielded a rich juice and were free from rotten cane.

Variety tests of wheat, oats, and potatoes, G. C. WATSON and E. H. HESS (*Pennsylvania Sta. Bul.* 39, pp. 15).—This is in continuation of work previously reported (E. S. R., 9, p. 832). The variety tests were made on twentieth-acre plats. The preparation and manuring of the soil and the seeding and cultivation of all plats of the different crops were as nearly alike as possible.

Wheat.—This season 31 varieties were grown. The yield of straw followed quite closely the production of grain. The Mealy variety produced the largest yield (42.93 bu. per acre), and the Reliable Minnesota the smallest (29.49 bu.), the one producing about 45 per cent more than the other. During a six-years' test the average yield of 5 of the most productive varieties was 24.4 per cent greater than the 5 least productive varieties. Of 16 varieties tested for eight years Reliable, Fuleaster, Ontario Wonder, Wyandotte Red, and Deitz Long Berry Red, in the order given, were the most productive, the average yields being over 30 bu. per acre. The results from varieties tested two, four, and five years are given in tables.

Oats.—Seventeen varieties were grown on duplicate plats, the results for each variety being the average of 2 plats. All varieties were sown at the rate of 8 pecks per acre on April 22. Prize Taker and Everett's Superior Scotch were ripe July 17; Improved American July 26, and Brancher, Buckbee New Illinois, and Black Tartarian July 29. All other varieties ripened about July 22. Henderson Clydesdale produced the largest yield (60.94 bu. per acre), and was followed in the order mentioned by Improved American, Buckbee New Illinois, Japan, Baltic White, German White, Victoria, and Wide Awake, the latter yielding 58.09 bu.

Potatoes.—The yields of 39 varieties of potatoes tested varied from

66.3 to 221.9 bu. per acre. The time of ripening varied from ninety-five to one hundred and sixteen days. The late varieties in general were the best producers. Great Divide, Irish Daisy, New White Peach Blow, Carman No. 1, and Carman No. 3, in the order given, produced the best yields.

Manuring meadows, L. GRANDEAU (*Jour. Agr. Prat.*, 1 (1898), No. 11, p. 150).—Barnyard liquor, barnyard manure, phosphoric acid, and a mixture of slag, kainit, and ammonium sulphate were applied to irrigated meadow lands. Analyses showed the soil to contain 0.182 per cent of nitrogen, 0.176 per cent of potash, and 0.095 per cent of phosphoric acid. The best results were obtained from the plat which received the mixture, the yield being at the rate of 11,657 kg. of hay per hectare. The plat which received the phosphoric acid yielded at the rate of 10,235 kg. of hay per hectare. These applications were profitable, but the barnyard liquor and barnyard manure were applied at a loss. The author recommends the use of nitrate of soda in the place of sulphate of ammonia on meadows which are not irrigated.

Alfalfa, or lucern, J. G. SMITH (*U. S. Dept. Agr., Farmers' Bul.* 31, pp. 23, figs. 3).—A revision of Farmers' Bulletin 31 of this Department (E. S. R., 7, p. 380).

Field beets, A. ARNSTADT (*Füdling's Landw. Ztg.*, 47 (1898), Nos. 5, pp. 183-186; 6, pp. 223-225).—Popular directions for the culture of field beets.

Breeding forage beets, A. KIRSCH (*Füdling's Landw. Ztg.*, 47 (1898), No. 7, pp. 288-289).—Notes on the culture and breeding of beets, with results of experiments along these lines.

Investigations with forage beets, G. PATUREL (*Ann. Agron.*, 24 (1898), No. 3, pp. 97-123).—A report on culture and variety tests, including the composition of forage beets.

The reproduction of beets by budding and by cutting, L. GESCHWIND (*Congress. Internat. Chim. Appl.*, 1896, II, pp. 227-234).—Directions for propagating beets by these methods and suggestions as to their value.

Cañaigre, F. MALET (*Bul. Dir. Agr. et Com.*, 2 (1897), No. 5, pp. 273-282, fig. 1).—Notes on the culture, composition, and industrial value of cañaigre.

Carrots as a forage crop, H. L. DE VILMORIN (*Jour. Agr. Prat.*, 62 (1898), No. 14, pp. 501-504, pl. 1).—Cultural notes are given and 6 varieties are described.

Cassava culture, C. K. MCQUARRIE (*Florida Farmer and Fruit Grower, n. ser.*, 10 (1898), No. 11, pp. 213, 214).—Popular notes on the culture of cassava.

Experiences in the culture of corn for the grain, F. VON LOCHOW (*Mitt. Deut. Landw. Gesell.*, 13 (1898), No. 6, pp. 85-89).—This article discusses the culture of corn in Germany.

Cowpeas, J. G. SMITH (*U. S. Dept. Agr., Division of Agrostology Circ.* 5, pp. 11).—A reprint from the Yearbook of this Department for 1896 (E. S. R., 9, p. 551).

Crimson clover, C. K. MCQUARRIE (*Texas Farm and Ranch*, 16 (1897), No. 39, p. 2).—Popular notes on growing crimson clover in the Gulf and South Atlantic States.

The effect of the direction of the rows on the yield, E. WOLLNY (*Deut. Landw. Presse*, 25 (1898), No. 27, p. 265).—The article discusses the results, which are given in tabular form. It was found that drilled crops in rows running north and south yielded more than when in rows extending from east to west.

Fertilizer experiments in 1897, F. MATHIAS (*Bul. Agr. [Brussels]*, 11 (1898), No. 1, pp. 15-19).—The results of fertilizer experiments on various farm crops during each year from 1886 to 1897 are given in tables.

Notes on the application of commercial fertilizers on meadows, J. SCHMIDBERGER (*Würt. Wehnl. Landw.*, 1898, No. 10, p. 134).

Establishing and manuring meadows, TANCRÉ (*Landw. Wehnl. Schleswig-Holstein*, 48 (1898), No. 13, pp. 219-224).—Directions for making and manuring meadows are given and grass mixtures for various soils and conditions are suggested.

Flax culture in Holland and Belgium, GISEVIUS (*Mitt. Deut. Landw. Gesell.*, 13 (1898), No. 7, pp. 97, 98).—The methods of flax culture and the development of the industry are discussed.

Heine's variety tests of oats, N. WESTERMEIER (*Deut. Landw. Presse*, 25 (1898), No. 22, p. 239).

Field culture of onions, H. KOCH (*Deut. Landw. Presse*, 25 (1898), No. 24, p. 263).—A note on the culture of onions as a field crop.

Comparative tests of varieties of potatoes, N. WESTERMEIER (*Deut. Landw. Presse*, 25 (1898), No. 27, p. 293).—A report on 147 varieties.

Culture experiments of the German potato experiment station in 1897 (*Deut. Landw. Presse*, 25 (1898), No. 24, pp. 261, 262).—The starch content and the yield of tubers and starch of the different varieties are given. The plan of the cooperative experiments is outlined and the different varieties are described.

Culture of the potato, MAIZIÈRES (*L'Engrais*, 13 (1898), No. 3, pp. 60-62, fig. 1).—A popular discussion, with recommendations for increasing the yield by the use of chemical fertilizers and the selection of seed.

The sugar beet in Norway (*Bl. Zuckerrübenbau*, 5 (1898), No. 6, pp. 80-90).—Notes on sugar-beet culture in Norway and a report on the results of variety tests of sugar beets carried on at the different experiment stations.

Culture experiment with sugar beets, SCHLÜTER (*Fühling's Landw. Ztg.*, 47

The culture of beets and the manufacture of sugar in Belgium, A. JADOUL (1898), No. 6, pp. 233, 234).—The results of a test of five varieties are reported. (*Rev. Gén. Agron. [Louvain]*, 7 (1898), No. 3, pp. 121-136).

The German beet-sugar industry, J. GOLDSCHMIDT (*U. S. Consular Rpts.*, 1898, No. 211, pp. 494-500).—The beet-sugar production of Europe in 1896-97 is reported by countries, and statistics are given to show the development of the industry in Germany. The beet-sugar legislation in Germany from 1839 to the present time is reviewed.

The soy bean in Provence, J. FARCY (*Jour. Agr. Prat.*, 62 (1898), No. 14, pp. 492-494, fig. 1).—This article treats of the culture of the soy bean and of its value for forage.

Sulla and its culture, V. DE LAFFITE (2. *Congrès Internat. Chim. Appl.*, 1896, II, pp. 241-250).—A description and history of sulla (*Hedysarum coronarium*), with full notes on its distribution and culture.

Silos and ensilage, M. D. ESHELEMAN (*Pacific Tree and Vine*, 14 (1898), No. 47, pp. 142, 143).—Popular notes.

Making and feeding stack silage (*Landmännern*, 8 (1897), No. 40, pp. 574-579).

Tobacco growing, R. S. NEVILL (*Queensland Agr. Jour.*, 2 (1898), No. 3, pp. 173-175, figs. 2).—Directions for the preparation of plant beds.

Cuban tobacco in Florida: How to grow it; how to cure it; how to make it pay, K. O. VARN (*Fort Meade, Fla.: The Author*, 1897).

Directions for curing heavy pipe and export tobaccos, R. S. NEVILL (*Queensland Agr. Jour.*, 2 (1898), No. 2, pp. 93, 94, pls. 3).

The cultivated vetches, J. G. SMITH (*U. S. Dept. Agr., Division of Agrostology Circ.* 6, pp. 7, figs. 4).—Four varieties of vetches—hairy or sand vetch, winter vetch, spring vetch, and kidney vetch—are described and directions given for their cultivation, with notes on their feeding and fertilizing value.

Culture experiments with sport varieties of barley, summer wheat, and oats in 1897, N. WESTERMEIER (*Fühling's Landw. Ztg.*, 47 (1898), Nos. 4, pp. 150-152; 5, pp. 173-176).—Six new varieties of barley, 7 of spring wheat, and 9 of oats were tested.

The results are given in tables and the comparative merits of different varieties pointed out.

Heine's variety tests of spring wheats, N. WESTERMEIER (*Deut. Landw. Presse*, 5 (1898), No. 29, p. 219).

Wheat growing by irrigation at Barcaldine, Queensland, W. H. CAMPBELL (*Queensland Agr. Jour.*, 2 (1898), No. 2, pp. 90, 91, pls. 2).—Particulars of experiments in wheat growing by irrigation with water from artesian wells.

Medeah wheat (*Agr. Jour. Cape of Good Hope*, 12 (1898), No. 5, p. 247).—A note on the history of this variety.

Fertilizer tests with wheat, H. J. WATERS (*Missouri Sta. Rpt.* 1897, pp. 9-19).—Reprinted from Bulletin 34 of the station (E. S. R., 8, p. 973).

HORTICULTURE.

Fruit growing in Wyoming, B. C. BUFFUM (*Wyoming Sta. Bul.* 34, pp. 85-157, figs. 3, pls. 36).—This bulletin reports the results with fruits at the experimental farms of the State since the first planting in 1892. Some of the trees have begun to bear, and so indicate what may be expected, but the time since planting has been too short to allow definite conclusions to be drawn. In many cases data regarding the various varieties of fruit are given in notes and tables. In order to show what can be done in the line of fruit growing in the State and also as a matter of history, all of the fruit farms of the State, as nearly as possible, are represented in the bulletin. The illustrations are from photographs. The bulletin also includes suggestions for the culture of orchard and small fruits, irrigation, and the like.

A comparison of eastern and western grown trees resulted in favor of the latter. In 1892 146 trees of 16 varieties from New York and 52 trees of 9 varieties from Colorado were planted. Some 38 per cent of the former died the first year, as against only 17 per cent of the latter. Of 40 trees of 3 hardy varieties of apples (Ben Davis, Oldenburg, and Wealthy) obtained from New York, 32.5 per cent died the first year, while of 18 trees of the same varieties from Colorado only 17 per cent died. The eastern trees were received in better condition than the western ones.

The following varieties have proved hardy and prolific in sections representing the larger portions of the State and, excepting grapes, may be expected to succeed in sheltered localities up to an altitude of something over 7,000 feet: *Apples*—Wealthy, Oldenburg, Ben Davis; *crab apples*—Siberian, Martha, Transcendent, Hyslop; *cherries*—Rocky Mountain Dwarf, Morello, Early Richmond; *plums*—De Soto, Weaver; *blackberries*—Early King, Stone Hardy, Wilson, jr.; *dewberries*—Lucretia, Mammoth; *currants*—Red Cherry, White Grape, Crandall, Lee Prolific; *gooseberries*—Houghton, Downing; *grapes*—Concord, Wyoming Red, Delaware; *yellow raspberries*—Caroline, Golden Queen; *red raspberries*—Turner, Hansel, Thompson Early Prolific, Marlboro; *black raspberries*—Kansas, Progress, Gregg, Lovett; *strawberries*—Warfield, Bubach, Mammoth, Sharpless, Gold, Cloud, Parker Earl, Shuster Gem, Wilson, Lady Rusk, Captain Jack, Viola, Bidwell, Triumph, Crescent

Seedling, Manchester, Cumberland, Staymen No. 1, Gandy, Jucunda Improved, Lovett Early, Iowa Beauty, Eureka, Mitchell Early, Hav-erland, and Jessie.

The culture of native plums in the Northwest, E. S. GOFF (*Wisconsin Sta. Bul. 63, pp. 67, figs. 32*).—The native plums of the species *Prunus americana* are considered among the hardiest of tree fruits. In the winter of 1896-97, the flower buds of the trees of this species were entirely uninjured while the buds of varieties of *Prunus domestica* were almost totally destroyed. The native plums are so productive as to require thinning the fruit to prevent injury from overbearing. A figure is given illustrating the tendency to overbear, and showing the effect of thinning. In the opinion of the author the quality of the best native plums is not inferior to that of the European plums, and reports of several growers show that their market value is fully as great. The propagation, culture, insect enemies, and diseases of the native plums are considered. Notes are given on some 180 varieties of native plums. In order to ascertain the cultural methods that are practiced in the Northwest inquiries were circulated among the more successful plum growers in that region. The replies are summarized in the bulletin.

Notes on pruning, F. W. CARD (*Nebraska Sta. Bul. 50, pp. 10, figs. 2*).—An experiment was begun in the year 1895 to determine the best time to prune apple trees, the best way of making the wounds, and the best treatment of them. Two trees were pruned the first of every month of the year. A few of the wounds on each tree were left rough as made by a saw, and a few were made smooth with some cutting instrument, like the chisel. At each pruning some of the wounds, both rough and smooth, were left untreated and others were treated with the following preparations: Liquid grafting wax, shellac varnish, white-lead paint, pine tar, and coal tar. Notes are given explaining the conditions under which the various prunings were made. Observations were made on the condition of the wounds throughout the year 1895, in the spring and autumn of 1896, and in the spring of 1897.

On account of the poor condition of the trees used, it was impossible to determine definitely the most favorable season of the year for pruning. There were some indications, however, that the wounds made during the growing season healed better than when made during the winter.

As to making wounds smooth or leaving them rough there was little difference between the two methods, what there was being in favor of rough pruning. The rough wounds seemed to heal slightly better, the wood checked somewhat less, and the materials applied stayed on slightly better.

Although untreated wounds were found to heal as well as any, except those covered with wax, they checked worst of all. In regard to the various materials applied, the author says:

“Taking all things together, nothing seems to be better for covering the wounds made in pruning than common lead paint, which is closely followed by grafting wax.

The wax is superior to paint in the matter of healing, but does not last as well and is not so convenient to apply, although in warm weather, when it works well, there is little trouble in this regard. Coal tar is useful in preventing the wood from checking, but appears to be a positive hindrance to healing, so that, in spite of the fact that it stays well, there is little to recommend it. Pine tar is no aid to healing, being apparently a true detrimental, while it helps only slightly in the matter of checking, and does not last well, therefore it has nothing to recommend it. Shellac is a failure. It does not last and neither aids the wound in healing nor, to any appreciable extent, prevents it from checking.

Results of thinning fruit in 1897 (*Canad. Hort.*, 21 (1898), No. 1, p. 117).—One tree of each variety of fruit tested was thinned and another as nearly like it as possible was left unthinned. About one-half of the fruit was removed in thinning. The apple and pear, it is thought, were thinned too late to give best results. In most cases the fruit on thinned trees was larger and better than that on the unthinned trees and in several cases the unthinned fruit was injured by rot. The results are given in the following table:

Results of thinning fruit.

Variety.	Time consumed in thinning.	Yield.	
		Thinned tree.	Unthinned tree.
	Hours.	Quarts.	Quarts.

Stimulating and holding fruit buds, H. E. GLAZIER (*Oklahoma Sta. Bul.* 31, pp. 15-18).—The author notes various methods of retarding the development of fruit buds of plums and reports a test of root pruning in this connection. Trees were root pruned by digging trenches about them, thus cutting the lateral roots. A treated tree was able to resist a greater degree of cold, made a greater growth the year following treatment, and produced much more fruit than an untreated one.

Strawberries and grapes, H. E. GLAZIER (*Oklahoma Sta. Bul.* 31, pp. 3-11, figs. 3).—Directions are given for the culture of strawberries in Oklahoma. Some 25 varieties of strawberries were tested, the majority of them giving good results. The dates of blooming, ripening, and first and last picking, and the yield of 19 varieties are tabulated. Brief notes are given on a number of varieties.

Grape growing in Oklahoma is discussed. A type of grape having small leaves and a tendency to deep rooting is thought best suited to the conditions of the Territory. For these reasons the Labrusca type is not well adapted to the region. A test of 175 varieties of grapes is reported. The parentage, date of ripening, color, and yield of the

varieties are given in tabular form. The author says: "In some instances the Labrusca stock has shown fairly good yields, as in the Concord and some others, but our complaint rests largely in the fault of uneven ripening, as is the case at the station."

Hybrid roses, gooseberries, and strawberries, J. L. BUDD (*Iowa Sta. Bul.* 36, pp. 868-878, figs. 6).—Brief notes are given on the most promising hybrid roses produced at the station, and on the best *Rosa rugosa* hybrids produced elsewhere and tested at the station. By way of summary the author says:

"Up to the present, our experience and observation favor the belief that the future favorite roses of the prairie States will be developed from the ironclad *Rosa rugosa* of east Europe and our native wild roses. It has been fully demonstrated that their hybrids, with our finest half-hardy varieties, follow largely the native species in hardiness of plant, perfect foliage, and complete unfolding of their flowers. It is also fully demonstrated that fine double varieties can be developed from primitive species in one generation."

Over 50 hybrids of the wild gooseberry of Manitoba, pollinated by the cultivated variety Champion, have fruited. In regard to this the author says:

"The leaves of all the hybrids are larger and thicker than those of either parent, and the fruit ranges in size on different plants from that of the Houghton to that of the Champion and Pearl. As compared with the latter sorts, the plants make fully twice as much annual growth of shoots, the leaves are larger and thicker, the thorns are stronger, but not as numerous, and the fruit has longer stems, favoring more rapid picking. . . . The great surprise of this experiment is the fact that not one of the hybrids follows the wild species in leaf, habit of growth, or fruit. The Champion pollen seems peculiarly prepotent. In all other work we have attempted in crossing on primitive forms, a large percentage of the seedlings have followed the mother very closely, often with very slight variations."

Crosses of the wild strawberry of Manitoba with pollen of cultivated varieties have not resulted satisfactorily. The author says: "We have secured the needed hardiness and perfection of leaf, but in no case have we secured the needed size for market or home use."

The cultivated species of asparagus, W. WATSON (*Gard. Chron.*, 3. ser., 23 (1898), Nos. 583, pp. 122-124, figs. 2; 585, pp. 147, 148, figs. 2; 587, pp. 178, 179, figs. 3).

American ginseng: Its commercial history, protection, and cultivation, G. V. NASH (*U. S. Dept. Agr., Division of Botany Bul.* 16, ser., pp. 32, figs. 5).—This bulletin has been revised by M. G. Kains.

To keep sweet potatoes (*Queensland Agr. Jour.*, 2 (1898), No. 2, p. 90).—Notes on the storing of sweet potatoes.

Observations on recent cases of mushroom poisoning in the District of Columbia, F. V. COVILLE (*U. S. Dept. Agr., Division of Botany Circ.* 13, ser., pp. 24, figs. 27).

Vegetable tests of 1897, L. R. TAFT, H. P. GLADDEN, and M. L. DEAN (*Michigan Sta. Bul.* 153, pp. 230-256).—The bulletin consists of descriptive notes and tabular data on most of the new and many of the standard varieties of beans, cucumbers, lettuce, peppers, cabbage, cauliflower, sweet corn, peas, and potatoes. The varieties that have proved most satisfactory are as follows: *beans*—Cylinder Black Wax, Flageolet (?), Victoria, Golden Wax, Red Valentine, Cream Valentine, Stringless Green Pod, Byer One Bean, and Improved Goddard; *cucumbers*—Russian, Choice, Westerfield

Poekling, White Spine, and Japanese Climbing; *lettuce*—Grand Rapids, Tennis Ball, Rawson Hot House, All Seasons, Half Century, Landreth Earliest, Italian Ice, Simpson Curled, and Wonderful; *tomatoes*—Vaughan Earliest, Atlantic, Leader, Ruby, Advance, Potato leaf Ignatum, Aeme, Beauty, Ignatum, Perfection, Optimus, Golden Queen, Muer, and Ponderosa; *cabbage*—Henderson Early Summer, Wakefield, Early Drumhead, All Head, Early York, Autumn King, Lupton, Mid-Summer, Succession, and World Beater; *potatoes*—Irish Cobbler, Six Weeks, Algoma, White Ohio, Huntington Peer, Woodhull, Accidental, Uncle Sam, Klondyke, Mill Banner, Good Times, Planet jr., Sir Walter Raleigh, Carman No. 1, Carman No. 3, Enormous, Rural New Yorker No. 2, Peachblow, Livingston Banner, and Beauty of Beauties.

Livingston's celery book, E. J. HOLLISTER (*Columbus, Ohio: A. W. Livingston's Sons, 1898, pp. 96, figs. 19*).—The book contains directions for the preparation of the soil, culture, and marketing of celery, based on twenty years' experience with the crop.

Preliminary report on Arkansas seedling apples, J. T. STINSON (*Arkansas Sta. Bul. 49, pp. 20, figs. 13*).—For several years the author has been investigating the seedling apples of Arkansas origin. In this preliminary report of the investigation descriptive and historical notes are given on twenty of the most important of these seedling apples.

American apples in Belgium, H. C. MORRIS (*U. S. Consular Rpts., 1898, No. 210, pp. 431-435*).

Manual of fruit-tree culture, A. BERNE (*Manuel d'arboriculture fruitière. Montpellier: Camille Coulet; Paris: Masson et Cie., 1898, pp. 301, figs. 147*).—The book treats of soils and fertilizers for fruit trees; planting, pruning, training, varieties, and diseases of fruit trees; the picking and storage of fruit, etc. A large part of the book is devoted to the methods of pruning and training.

Damage from cold and best methods of prevention (*Florida Agr., 25, No. 18, pp. 173-175*).—This is an address by the president of the Florida State Horticultural Society on the damage of cold to orange groves and means of preventing it.

Future of some of our native fruits, nuts, and shrubs, J. L. BUDD (*Iowa State Hort. Soc. Rpt., 32 (1897), pp. 318-320*).

Winter protection of the peach, J. C. WHITTEN (*Missouri Sta. Rpt. 1897, pp. 140-159, figs. 5*).—Reprinted from Bulletin 38 of the station (E. S. R., 9, p. 835).

Cultivation and management of the peach, J. C. WHITTEN (*Missouri Sta. Rpt. 1897, pp. 159-161*).—Reprinted from Bulletin 38 of the station (E. S. R., 9, p. 837).

Cooperative experiments with small fruit, D. T. PRICE (*Mississippi Sta. Bul. 46, pp. 8*).—The bulletin gives variety tests and directions for the culture of strawberries, raspberries, blackberries, and grapes. From tests of some 50 varieties of strawberries, the author recommends the following for northeast Mississippi: Lady Thompson, Crescent, Bubach, Tennessee Prolific, Brandywine, and Lovett. Tests of a limited number of varieties of raspberries and blackberries are reported. Turner was the only red raspberry and Gregg the only black raspberry that was satisfactory. Of the blackberries tested, Dallas, Snyder, Erie, Lawton, and Taylor did well. Of the 33 varieties of grapes tested, Poeklington, Triumph, Reissling, and Moore Early proved the best.

Notes on small fruits grown in 1897, F. H. HALL (*New York State Sta. Buls. 127 and 128, popular ed., pp. 5*).—A popular edition of Bulletin 127 and 128 of the station (E. S. R., 9, p. 1052).

Raspberries, blackberries, and grapes, L. R. TAFT and H. P. GLADDEN (*Michigan Sta. Bul. 151, pp. 163-169*).—The results of tests of 40 varieties of raspberries and 19 of blackberries are given in tables and descriptive notes. Notes are also given on some 20 varieties of grapes. The following varieties of raspberries were most promising: *black*—Palmer, Courath, Kansas, Gregg, Older, Black Diamond, and Mills No. 15; *purple*—Shaffer, Columbian, Beckwith, and Redfield; *red*—Cutlbert, London, Marlboro, Hansell, Phoenix, and Stayman No. 1.

Strawberry growing in New Hampshire, F. W. RANE (*New Hampshire Sta. Bul.*

47, pp. 91-114, figs. 7).—A test of 51 varieties of strawberries is reported. A table is given showing the size and character of the foliage, the tendency to produce runners and form a matted row, and the amount of blight. The fruit of each variety is illustrated. Notes are given on 12 of the more popular varieties. The bulletin also contains directions for the culture of strawberries and notes from local strawberry growers. G. F. Beede gives a report of tests of a large number of varieties during five years. The varieties on the merits of which strawberry growers are agreed are: Bubach, Crescent, Lovett, Warfield, Greenfield, Haverland, Beverly, May King, Sharpless, Marshall, and Michel Early.

Barrel strawberry culture, J. P. OHMER (*Amer. Gard.*, 19 (1898), No. 172, p. 387, fig. 1).—Directions for growing strawberries in barrels.

Report of South Haven Substation, T. T. LYON (*Michigan Sta. Bul.* 152, pp. 171-229).—The bulletin reports tests of 163 varieties of strawberries, 65 raspberries, 30 blackberries, 22 currants, 20 gooseberries, 76 cherries, 511 peaches, 148 grapes, 110 plums, 96 pears, 19 crab apples, 135 apples, and 11 quinces. The results are given in tables showing such data as dates of blooming and ripening, vigor and productiveness of plants, form, color, quality, and size of fruits, and the like, the tables being accompanied by descriptive notes. Notes are also given on dewberries, service berries, almonds, chestnuts, pecans, hazelnuts, walnuts, apricots, mulberries, nectarines, asparagus, and rhubarb.

Viticulture, P. COSTE-FLORET (*Les travaux du vignoble. Montpellier: Camille Coulet; Paris: Masson et Cie., 1898, pp. 418, figs. 121*).—The book belongs to *Bibliothèque du "Progrès Agricole et Viticole."* It treats of the propagation and culture of grapes, soils and fertilizers, insects, diseases, and the like.

The chrysanthemum: Its past, present, and future, E. M. WOOD (*Trans. Massachusetts Hort. Soc., 1897, 1, pp. 28-42*).

The dahlia: A practical treatise on its habits, characteristics, cultivation, and history, L. K. PEACOCK (*Atco, N. J.: W. P. Peacock, 1896, pp. 56, figs. 11*).—The book treats of the propagation, classification, culture, and varieties of the dahlia, with chapters on dahlia exhibitions, the American Dahlia Society, etc.

The sweet pea, W. T. HUTCHINS (*Trans. Massachusetts Hort. Soc., 1897, 1, pp. 46-60*).

The propagation of orchids (*Amer. Florist, 13 (1898), No. 516, pp. 1132, 1333*).

The selection of trees, shrubs, climbers, and their disposition, G. W. CARRUTHERS (*Amer. Gard.*, 19 (1898), No. 176, Sup., pp. 10, 11).

Experiments in the use of commercial fertilizers (*Wiener Illus. Gart. Ztg., 23 (1898), No. 4, pp. 143-150*).—The report of the experiments of A. Hébert and G. Trnftant in the application of commercial fertilizers to various ornamental plants is translated from *Journal de la Société nationale d'horticulture de France*.

Experiments in fertilizing potted plants with nutrient salt solutions, R. OTTO (*Gartenflora, 47 (1898), No. 8, pp. 210-213, figs. 2*).—*Heliotrope*, *pelargonium*, *Fuchsia hybrida*, *Salvia splendens*, and *Pentstemon gentianoides* were watered with a nutrient solution at intervals of from five to eight days, being watered at other times as needed with ordinary water. The nutrient solution consisted of a mixture of 6 parts ammonium phosphate, 5 parts sodium nitrate, 5 parts potassium nitrate, and 4 parts ammonium sulphate dissolved in water at the rate of 1 part of the mixture to 1,000 parts of water. Other plants of the same kinds were watered entirely with ordinary water as a check. The plants watered with the nutrient solution were of a deeper green color than the others, had larger leaves, more numerous and generally more vigorous branches, earlier flowers, and more abundant flowers and fruit.

The horticultural directory and yearbook for 1898 (*London: Journal of Horticulture, 1898, 39 ed., pp. 480*).—The directory contains alphabetical lists of the nurserymen, seedsmen, and florists, of the gardeners, of horticultural builders, and engineers, of botanical gardens and public parks, of the seats of the nobility, and of the botanical, horticultural, and floral societies of Great Britain and Ireland; county lists of nurserymen, seedsmen, and florists in England and Wales, in Scotland, in Ireland, and in the Channel Islands, and of the seats of the nobility in Great Britain

and Ireland; list of the principal nurserymen, seedsmen, and florists of European countries, and the British colonies; of landscape gardeners, and of commission merchant and salesmen at the Covent Garden Market, London; and tables, receipts, and miscellaneous information of interest to horticulturists.

Garden making: suggestions for the utilizing of home grounds, L. H. BAILEY (*New York: The Macmillan Co., 1898, pp. 317, figs. 256*).—The book is one of the *Garden craft series*. It contains a chapter on such topics as preparation of the land, sowing and planting, winter protection, forcing plants, insects and diseases, etc.; a chapter on the plan of the place, including discussions of the "picture in the landscape," the fundamentals of landscape gardening, specific examples, and how the improvements are made; a chapter on planting the ornamental grounds, containing a list of ornamental plants hardy in central Michigan, and remarks by Ernest Walker on plants for floral effects, flower beds, carpet-bedding, borders, annuals, bulbous and tuberous plants, hardy herbaceous perennials, climbing plants, etc.; a chapter on the fruit plantation, contributed largely by L. R. Tait, and including the grape, small fruits, northern orchard fruits, and subtropical fruits; a chapter on the vegetable garden, written in large part by F. A. Waugh; and a chapter on seasonal reminders, giving monthly calendars of garden operations for the North by T. Greiner and for the South by H. W. Smith and F. H. Burnette.

Greenhouse management, L. R. TAIT (*New York: Orange Judd Co., 1898, pp. 382, figs. 128*).—This is a manual on the forcing of flowers, vegetables, and fruits in greenhouses and on the propagation and care of house plants. Chapters are devoted to the insect enemies and fungus diseases of greenhouse plants and the preparation and use of insecticides and fungicides.

FORESTRY.

Notes on the annual growth of forest trees, W. R. LAZENBY (*Proc. Soc. Prom. Agr. Sci., 1897, pp. 15-19*).—This is the presidential address delivered by the author at the Detroit meeting of the Society. The importance of growing forest trees and the preservation of woodlands is pointed out, and the author urges the planting of forest trees for timber, shelter, and protection, as well as for ornament and landscape effect.

A report is given on an experiment begun in the fall of 1882, in which the seeds of a dozen or more varieties of native forest trees were collected and placed under suitable conditions for planting the following spring at Columbus, Ohio. The species selected were wild black cherry, black walnut, black locust, sugar maple, catalpa, red maple, cucumber tree; white, black, and blue ash; bur, scarlet, and yellow oaks; American chestnut, Kentucky coffee tree, and beech. The seeds were planted in the spring of 1883, and, with the exception of the chestnuts, oaks, and black walnuts, all the trees were transplanted from the seed bed when a year old. The trees were grown in rows $3\frac{1}{2}$ ft. apart and 2 ft. in the row. Careful cultivation was given for the first few years until the trees had attained sufficient size to shade the ground, when no further cultivation was needed. Notes were taken from time to time on the annual growth and diameter, and the following observations were made relative to the growth of the trees:

"(1) The increase in diameter of trunk did not bear a constant ratio to the increase in height, but appeared to be mainly dependent upon the leaf development. That

is, when the plantation was thinned the trees invariably branched lower, and while making a more rapid increase in diameter made a slower upward growth.

"(2) Some species grew with great uniformity, despite the variation in season, while others presented a considerable difference from year to year. For example, the catalpa, white ash, and yellow locust represented the greatest variation in annual growth, both in height and diameter. The black cherry, black walnut, honey locust, and oaks showed the least variation. In all cases the growth was the greatest when there was the most rainfall during the growing season.

"(3) When the foliage was injured or removed early in the season, or the early growth was arrested by a severe drought, it took several years to overcome this check to normal increase, no matter how favorable the seasons were immediately following.

"(4) The greatest annual increase in diameter of trunk invariably took place in the side most fully exposed to the light, but the greatest growth in length of branches was often on the side not fully exposed. That is, although there was a greater aggregate growth of limbs and branches on the most exposed side, the greatest growth in length of single branches was frequently on the shady side.

"(5) But one so-called 'annual ring' was formed each growing season, and this was usually so well defined as to be easily counted. As a rule these rings furnish not only a convenient but reliable record of the age of trees.

"(6) The trees that made the most rapid growth were the following: Yellow locust, black cherry, catalpa, white ash, and black walnut."

The average height and diameter of ten specimens of several varieties at the end of fifteen seasons' growth are shown in the following table:

Growth of trees in fifteen seasons.

	Diameter. Height.	
	<i>Feet.</i>	<i>Feet.</i>
Yellow or black locust	9.0	42.00
Black cherry	7.8	38.00
Catalpa	8.2	34.00
White ash	6.1	36.75
Black walnut	6.0	35.50

The most rapid growth for any one year was made when the trees were three years old. The growth during this season was as follows: Yellow or black locust, 5 ft. 1 in.; black cherry, 4 ft. 3 in.; catalpa, 3 ft. 7 in.; white ash, 4 ft. 10 in.; and black walnut, 3 ft. 7 in.

Forestry conditions and interests of Wisconsin, F. ROTH (*U. S. Dept. Agr., Division of Forestry Bul. 16, pp. 76, pl. 1*).—This bulletin is a report, by the author, of investigations made during the summer of 1897, in cooperation with the State Geological Survey of Wisconsin. An introductory chapter is given by B. E. Fernow, chief of the division, in which the object and methods of the investigation are outlined and some conclusions and recommendations given. The inquiry was undertaken in order to ascertain definite and authoritative knowledge regarding the forest conditions of one of the most important regions of lumber production. The wooded area of this region is steadily being reduced by logging, and to some extent by clearing, and little or nothing is done either to restock or protect the cut-over lands. The present system is estimated to cause an annual loss of about 800,000,000 feet of lumber. Of the 17,000,000 acres of forest lands, more than 8,000,000

have been cut and largely burned over, so that it is said nearly one-half of the area is reduced almost to a desert condition.

The author reviews the forest conditions of the past and present, and the supplies of white, red or Norway, and jack pine, hemlock, cedar, tamarack, spruce, and balsam fir, together with hard-wood supplies. The possible rate of accretion is given, but this growth is greatly reduced by clearing, logging, and forest fires. The effect of the forest on climate and rainfall is stated. The author claims that many of the rivers heretofore navigable or furnishing a large water supply have been so reduced as to have their former utility greatly impaired. The extent and injury of forest fires in the State are mentioned, and suggestions offered for reducing them to the minimum. The forest conditions in different counties are given in some detail, together with lists of the principal forest trees of northern Wisconsin, the surface features of the State, amount of standing timber, etc.

Forest technology and uses of wood, P. RIZZI (*Tecnologia forestale ed utilizzazione dei boschi*. Milan: F. Vallardi, 1897, Vol. I, pp. VII+221; 1898, Vol. II, pp. 110, ill.).

Forest-zoological guide, C. KELLER (*Forstzoologischer excursions fñhryer*, pp. 277, figs. 28. Leipzig and Vienna: Carl Fromme, 1897; abs. in *Zool. Centbl.*, 5 (1898), No. 4, p. 109).—An introduction to the study of forest injuries. The subject is considered from the standpoint of leaf, bark, and wood injuries; injuries in mountains, and finally, injuries by mammals are considered. In an appendix all injuries are arranged according to the species of tree affected. The work is of value for its arrangement.

How to apply forestry in spruce lands, A. CARY (*Forester*, 4 (1898), No. 3, pp. 59-61).—The author reviews the general forest conditions of Maine and northern New Hampshire, referring particularly to the spruce timber, and gives in considerable detail the trees found on a half acre of heavy spruce timber in northern New Hampshire. He shows how that about 3,000 ft. of timber could be taken from this land, which would in no way diminish the value, but would rather improve the growth of what was left.

Wood pulp supplies and forestry, B. E. FERNOW (*Forester*, 4 (1898), No. 3, pp. 52-56).—The author in an address read before the American Paper and Pulp Association, at its meeting February, 1898, pointed out the rapid development of the paper pulp industry and the rate of consumption of timber and the possible advantage of forest management for the continued production of pulp wood.

Notes on Pinus rigida, DE LAPASSE (*Rev. Eauz et Forñts*, 3, ser., 2 (1898), No. 3, pp. 291-295).

Forest growth and sheep grazing, F. V. COVILLE (*U. S. Dept. Agr., Division of Forestry Bul.* 15, pp. 54).—This bulletin is a report of observations made regarding the effect of sheep grazing on forest growth in the Cascade Range Forest Reserve. The author concludes that sheep grazing without proper restrictions and regulations is detrimental to the reproduction of forest growth, to soil conditions, and to water-flow. Wherever forest growth is to be maintained and the washing of soils, with consequent flood dangers, avoided, the greatest care and judgment should be exercised as to the manner in which sheep grazing may be carried on without detriment.

Forest trees, H. LOUBIÉ (*Les essences forestiñres*. Paris: Masson et Cie., 1898, pp. 191).—Treats of the species of trees that yield resin.

The development of state forestry in Saxony, FÜRST (*Forstw. Centbl.*, 20 (1898), No. 4, pp. 192-197).

Forest conservation, A. J. BOYD (*Queensland Agr. Jour.*, 2 (1898), No. 2, pp. 154-158, pl. 1).

Notes on the growth of forest trees, A. HEIMERL (*Wiener Illus. Gart. Ztg.*, 23 (1898), No. 3, pp. 95-110, figs. 2).

Investigations in the stand of forests, ZIELASKOWSKI (*Zischr. Forst u. Jagdw.*, 30 (1898), No. 3, pp. 159-157, figs. 5).

Report on culture experiments with Japanese, Indian, Russian, and American forest trees in Bavaria, H. MAYR (*Forstw. Centrbl.*, 20 (1898), Nos. 3, pp. 115-131; 4, pp. 153-190, figs. 2).

The reforestation of mountains, B. DE LA GRYE (*Rev. Eaux et Forêts*, 3. ser., 37 (1898), No. 3, pp. 69-82).

The reforestation of the Loire basin, C. BROILLIARD (*Rev. Eaux et Forêts*, 3. ser., 2 (1898), No. 8, pp. 241-253).

The fertilization of forests, A. THEZARD (2. *Congrès Internat. Chim. Appl.*, 1896, II, pp. 190-226).

Japanese and Chinese conifers, MAXWELL T. MASTERS (*Bul. Herb. Boissier*, 6 (1898), No. 4, pp. 269-274).—*Pinus scipioniformis* is described and critical notes are given of other species. A list of 34 species of coniferous trees occurring in Japan is given. The specimens determined are in the De Candolle and Boissier herbaria.

The Robinia and Sophora (*Rev. Eaux et Forêts*, 3. ser., 37 (1898), No. 5, pp. 149-154).—Notes are given on *Robinia pseudacacia* and *Sophora japonica*.

Osier culture, A. SCHMID (*Die Anpflanzung und Behandlung der Korb- und Bandweiden*. Stuttgart: E. Ulmer, 1898, 2. ed., pp. 116, pls. 4, figs. 20).

Concerning the production of the cork oak (*Jour. Soc. Agr. Brabant-Hainaut*, 1897, No. 52).

American oaks, J. HOUBA (*Bul. Soc. Cent. Forst. Belg.*, 5 (1898), No. 4, pp. 263-283).

The distribution of pines in Cevennes, G. FABRE (*Rev. Eaux et Forêts*, 3. ser., 37 (1898), No. 6, pp. 176-178).

Wyoming junipers, A. NELSON (*Bot. Gaz.*, 25 (1898), No. 3, pp. 196-199, figs. 2).—The relationship of the species of *Juniperus* is discussed and *J. knightii* n. sp. is described and figured.

Late and early frosts in their relation to forestry (*Mittrich*, 30 (1898), No. 4, pp. 201-233).

SEEDS—WEEDS.

Report of the Danish seed control for 1896-97, O. ROSTRUP (*Copenhagen: 1898*, pp. 37).—The report shows that 1,762 samples of seeds were examined from July 1, 1896, to June 30, 1897. Of this number 934 samples were from seed dealers, 69 from seed growers, 508 from farmers, and 251 samples for original investigations. Complete analyses were made of 1,184 samples, purity determinations of 243 samples, germination tests of 310 samples, and miscellaneous determinations of the remainder. A summary of the results of Danish seed analyses made during the period from 1887 to 1897, inclusive, is given.

The author states that in testing seed there are usually somewhat more hard seed in legume seed during the fall months than at sowing time in the spring. If all samples examined had been tested in the fall, the percentage of hard seed would have been as follows: For red clover, 8 per cent; white clover, 16.4 per cent; alsike clover, 4.5 per cent; black medick, 4.5 per cent; lucern, 6.2 per cent; and *Athyllis ruberaria*, 7.1 per cent; or 1.5, 0.3, 1.0, 0.2, 1.0, and 1.1 per cent, respectively, greater than the results obtained in the spring.

The different kinds of weed seeds were determined in the seed samples and results are summarized in the report.

The author investigated the effect of concentrated sulphuric acid on "hard" seeds. It is well known that hard seed coats of wild or cultivated legumes can be prepared, both by mechanical means and by the aid of chemicals, so as to allow water to penetrate the seed coat more easily and effect germination. A sample of *Lathyrus sylvestris* seed was steeped in concentrated sulphuric acid for one minute and the germination of the seed thus treated compared with untreated seed with results as follows:

Effect of sulphuric acid on germination of Lathyrus sylvestris.

Time of germination.	Percentage of germination.	
	With sulphuric acid.	Without sulphuric acid.
1 to 20 days.....	16	2
20 to 40 days.....	52	14
40 to 60 days.....	16	12
60 to 80 days.....	8	4
80 to 100 days.....	0	10
120 days.....	8	34
Total.....	100	76

The expenses of the control station during 1896-97 were 12,740.22 crowns (\$4,754), covered by analysis fees received and by a Government appropriation of 5,678.47 crowns (\$2,119).—F. W. WOLL.

Seed testing. C. R. BALL (*Iowa Sta. Bul.* 36, pp. 856, 857).—Brief notes are given on European seed control, the progress of seed testing in America, and seed testing in Iowa. Tables are given showing the results of two tests made at intervals of one hundred days with lettuce, parsnip, and watermelon seed. The seed was secured from five different firms, and shows quite a range in the germination of the different samples. The lettuce seed had depreciated greatly in the interval existing between the two experiments. The germinative power of the parsnip seed was slightly higher at the time of the second trial, and the watermelon seed gave a much better germination at the second testing.

Dodders infesting clover and alfalfa. L. H. DEWEY (*U. S. Dept. Agr., Division of Botany Circ.* 14, pp. 7, figs. 2).—Notes are given on the occurrence of some injurious species of dodder, methods of propagation, distribution, and suggestions for their eradication. The species in the United States which are considered injurious to economic crops are the following: Alfalfa dodder (*Cuscuta epithymum*), flax dodder (*C. epilinum*), clover dodder (*C. racemosa chiliana*), warty dodder (*C. indecora*), and field dodder (*C. arvensis*).

Massachusetts weeds. G. E. STONE (*Massachusetts State Bd. Agr. Rpt.* 1897, pp. 268-277).—A statement is given of the introduction and spread of numerous weeds, together with a list of 30 species of the worst weeds, with directions for their eradication.

Plants reputed poisonous to stock. F. M. BAILEY (*Queensland Agr. Jour.*, 2 (1898), No. 2, pp. 131-133, pl. 1).—All species of the Cycadaceæ are reputed pois-

onous to stock grazing upon their herbage. *Macrozamia niqullii* is considered most injurious, as it is believed to produce in cattle a disease called "rickets." The disease causes a lack of control over the movements of the hind legs. Young stock in poor condition seem most subject to the disease. Affected animals may improve, but they are said never to completely recover.

DISEASES OF PLANTS.

The olive knot, F. T. BIOLETTI (*California Sta. Bul.* 120, pp. 11, pls. 3, fig. 1, dgm. 1).—The author reports the recent discovery in Merced County, California, of the disease known as olive knot, which is said to be caused by *Bacillus oleæ*. Attention is called to the lack of satisfactory curative measures and the importance of quarantine regulations against infected nurseries or olive groves.

This disease, which has been known for some time in Southern Europe and elsewhere, seems to be widely extended, but the specific cause was not known until 1886, when the specific organism was separated and the disease produced by means of inoculation. The disease was first noticed in the orchard referred to above in 1893 on a single tree. Since that time it has spread over a large part of the orchard. The author visited the place in February, 1898, and made a somewhat limited study of the disease. In the orchard were 141 olive trees, 6 of which have been destroyed, 43 are seriously injured, 69 show numerous knots, while the remaining 23 show little or no evidence of disease. While there is but little evidence upon which to base judgment relative to susceptibility, in this orchard some varieties seemed more resistant than others, since some were not affected, although surrounded by badly diseased trees.

The roots of the trees seemed but little affected. On the trunks, wherever there was a jagged wound, such as is made by breaking off a branch or a blow by a plow, the knots were very numerous, the edge of the wound evidently serving as a place for infection. Occasionally small tubercles, varying from the size of a pin head to that of a pea, are found on the leaves, generally on the under side. The occurrence of affected leaves is very irregular, some of the most badly affected trees showing no tubercles on the leaves. The effect on the fruit could not be definitely ascertained. The owner of the orchard stated that the fruit seemed to be affected, as many olives rotted while undergoing the process of pickling. The nature and symptoms of the disease are given at some length, largely quoted from Savastano's description.¹

The author conducted some experiments in a laboratory with knots collected during the winter at the time of his visit, but the material was very unfavorable, most of the knots being old and dry. However, a few were found which were still unbroken, and from the interior of these cultures were made, five of which agreed morphologically with the organism to which has generally been attributed the cause of the disease.

¹ Compt. Rend. Acad. Sci. Paris, 103 (1886), p. 1114.

In his conclusions the author states that the olive knot disease is at present limited to a very small range in California, but as it promises to be very harmful in some localities special precautions should be taken to prevent its spread. The conditions which favor the growth of the organism are delicacy of tissue owing to vigorous growth or variety, high sap pressure, wounds, and hot weather. Various precautions are suggested to be observed in pruning and caring for trees lest the disease may be spread. The author believes that olives from diseased trees are perfectly wholesome and may be used for oil purposes unless the vitality of the tree is seriously affected, but that the fruit is probably useless for pickling.

A destructive disease of maize, M. RACIBORSKI (*Ber. Deut. Bot. Gesell.*, 15 (1897), No. 8, pp. 475-478, fig. 1).—The author reports the occurrence in Java of a very destructive disease of maize due to an apparently undescribed fungus, *Peronospora maydis*.

The disease attacks the young plants, the first two or three leaves appearing healthy, but the subsequent ones becoming white or very light green. Later the leaves change to such a degree that the white spots may be seen at quite a distance. The appearance of the discolored leaves is followed by the wilting and death of the plants. Examination of the diseased leaves showed the presence of a uniseptate mycelium which bears very numerous haustoria. Through the stomata appear the conidiophores, which are 3 mm. high, 25 μ in diameter, and from 3 to 6 times dichotomously branched. The conidia are spherical, 15 to 18 μ in diameter, and germinate in a few hours, producing one or more hyphae. Culture experiments showed that the conidia when inoculated upon the leaves of maize produced the characteristic spotting within twelve to eighteen days after the first infection. The oogonia are 18 to 25 μ in diameter, with a not very thick but resistant membrane, which bears a few small, conical thickenings.

While the disease is evidently spread by the conidia being blown about by the wind, the author thinks the oospores in the soil the chief method of infection. The usual practice of alternating sugar cane and maize would tend to increase the liability to disease through the presence of innumerable oospores in the soil where the young maize plants have grown.

Thus far the disease is known only from Java, and it is thought possible that the fungus may have been introduced upon the maize from some of the native grasses. The introduction of the disease into the great maize-growing countries would be deplorable.

The diseases of the sugar cane in Java, J. H. WAKKER AND F. A. F. C. WENT (*De Ziekten van het Suikerriet op Java. Leiden: E. J. Brill, 1898, pp. 217, pls. 25*).—The authors describe, figure, and, where known, give remedial measures for the various diseases to which sugar cane in Java is subject. The diseases are grouped into four classes, those of the stalk, leaf sheath, leaf blade, and root. In addition, the gummosis of the sugar cane is discussed.

The diseases treated of are: Stalk diseases—smut (*Ustilago sacchari*), red rot (*Colletotrichum falcatum*), ananas disease or black rot (*Thielariopsis ethaceticus*), *Marasmius sacchari*, top rot, several forms of the seroh disease, and a striped disease; of the leaf sheath—eye spot (*Cercospora vaginæ*), red rot (*Sclerotium* sp.), sour rot (*Sclerotium* sp.); of the leaf blade—yellow spot (*Cercospora Köpkei*), *Sclerotium* sp., rust (*Uredo Kühnei*), ring spot (*Leptosphaeria sacchari*), red spot (*Eriosphaeria sacchari*), eye spot (*Cercospora sacchari*), leaf spot (*Pestalozzia fuscescens sacchari*), a disease causing a striped appearance of the leaves; root diseases—root rots, some of which are due to *Cladosporium javanicum* and *Allantospora radiculicola*.

In addition, the authors give a list of saprophytic fungi which have been observed on the sugar cane in Java, together with technical descriptions of the following new species of fungi: *Colletotrichum falcatum*, *Thielariopsis ethaceticus*, *Hypocrea sacchari*, *Marasmius sacchari*, and *Allantospora radiculicola*.

Rhizoctonia strobi, a new disease of **Pinus strobus**, E. SCHOLZ (*Verhandl. K. K. Zool. Bot. Gesell. Wien*, 47 (1897), No. 8, pp. 541-557, figs. 6).—The author figures and describes a new parasite of the white pine. The attacks of the fungus were noticed in a 13-year-old mixed plantation of pines. The disease, however, seemed to be confined to the one species, although *Pinus parolinii* was abundant. Several of the trees are dead, and hundreds show the presence of the fungus. During the growing season the diseased trees appear wilted; the leaves on the lower branches become yellow or reddish in color and tend to turn downward. On the dying trees they become brown and in the later stages fall off. A changed appearance in the color of the trunks is noticed, especially near the collar of the tree. In this part of the tree an abundant mycelium is found. The fruiting bodies of the fungus have not been found.

A number of successful inoculation experiments are reported in which the fungus was transferred to some trees and the disease was developed.

But little is known about means of preventing the disease, but the fungus is thought to gain entrance primarily through the soil. The use of lime on infected soil has not given advantageous results.

The author has given the name *Rhizoctonia strobi* to the fungus.

On the viability of the winter spores of certain rust fungi, J. ERIKSSON (*K. Landt. Akad. Handl. Tidskr.*, 36 (1897), No. 6, pp. 371-388).—This is a report of investigations conducted by the author during the years 1895 and 1896. The main conclusions drawn from the results obtained are summarized as follows:

The winter spores of the black and crown rust fungi are viable during the spring following the fall when they formed, provided they have been outdoors during the winter, exposed to alternate frost and thaws, snow and rain.

In the open air, under the climatic conditions prevailing at Stock-

holm, Sweden, the spores germinate during the months of April and May. If the viable spores are prevented from germinating at the regular season by keeping the rusty straw dry and indoors, their viability will be preserved during the succeeding summer and fall, into the month of September or even until October.

The vitality of the spores of the black rust of oats, rye, or barley generally diminishes to such an extent that they are incapable of spreading disease after a year, whether kept in or out doors. Black rusty wheat straw seems to preserve its disease-spreading faculty somewhat longer, more than a single winter, but practically speaking may be considered almost without importance.

If the spreading of grain rust is prevented by cutting, removing, and burning black rusty straw of quick grass and other grass along ditches, etc., the work should be done either late in the fall or very early in the spring, as soon as the snow is gone, so that the spores on the rusty straw shall not succeed in germinating in April or the beginning of May, and thus contribute to the spread of disease in its immediate vicinity.—F. W. WOLL.

Annual report of the superintendent of spraying for Ontario, 1897 (*Ontario Dept. Agr., Toronto, 1898, pp. 16*).—A detailed report is given of the work conducted under the supervision of the author in spraying for the prevention of fungus diseases of orchard fruits.

In addition to spraying with fungicides for the prevention of diseases, experiments were made in spraying fruit trees while in bloom with ice water to ascertain the effect of cold rains on the fertilization of flowers and the setting of fruits, also to ascertain whether with heavy blooming the flower could not be partially sterilized in this way, thus saving the labor of thinning the fruit. Three peach trees, 3 plum trees, 3 pear trees, and 1 apple tree were selected for the work, the trees being in full bloom or just coming into bloom. Water cooled with broken ice was used, and the trees were thoroughly drenched for some time. All the trees were sprayed May 13, 14, and 15, and all except the peach trees again on May 17 and 18. The results were carefully watched, and no difference could be observed on the crop from the sprayed and unsprayed trees of the same variety, nearly 100 per cent of the blossoms setting in every case.

It would appear from the results of this experiment that cold rains during the blossoming period do not injure the blossoms unless the rains are so prolonged as to interfere with proper fertilization.

The alfalfa leaf spot disease, R. COMBS (*Iowa Sta. Bul. 36, pp. 858, 859, fig. 1*).—The author figures and describes the cause of alfalfa leaf spot (*Pseudopeziza medicaginis*). The history of the disease and estimations of the probable loss caused by it are given.

On the barberry bush as a carrier and spreader of grain rust, J. ERIKSSON (*Landtm. Manadsbl., 1897, No. 11, pp. 167-173*).

Principal results of the studies on grain rusts, J. ERIKSSON (*Rev. Gén. Bot., 10 (1898), No. 110, pp. 33-48, fig. 1*).—Essentially the same article as in Botanical

Gazette, 25 (1898), No. 1, pp. 26-28. Both are editions of the same article which has appeared in Swedish.

Notes on some diseases of trees, L. SAVASTANO (*Bol. Soc. Nat. Naples*, 11 (1897), pp. 109-127).—The author gives notes on the following diseases: Rot of Indian fig, a bacterial disease of grapes and olives, rot and gummosis of medlars, canker of poplars, the Californian disease of grapes at Sorrento, spoiling of lemons, etc.

Report on the disease of chestnuts in Limousin, Auvergne, Perigord, etc., L. CRIÉ (*Bul. [Min. Agr., France]*, 17 (1898), No. 1, pp. 148-161).

A disease of chestnut trees, A. MATHEY (*Rev. Eaux et Forêts*, 3. ser., 2 (1898), No. 7, pp. 226-229).—The attack of *Agaricus melleus* and other fungi is mentioned, and the author states that much of the loss could be prevented by better attention to the trees.

Rose leaf blight, B. D. HALSTED (*Amer. Florist*, 13 (1898), No. 512, p. 951, figs. 2).

The black speck of the rose, B. D. HALSTED (*Amer. Florist*, 13 (1898), No. 517, p. 1170, figs. 2).—Notes are given of a disease of rose leaves due to attacks of *Ptilobolus crystallinus*. Withholding manure from underneath the bushes and applications of fungicides are recommended as preventive measures.

The production of gum on cannas, M. L. LUTZ (*Bot. Gaz.*, 25 (1898), No. 4, pp. 280, 281).

The lily disease (*Florists' Exchange*, 10 (1898), No. 16, p. 407).—The author maintains that *Lilium harrisii* will not stand overwatering or other injury, the disease quickly following such treatment.

Diseases of variegated plants, B. D. HALSTED (*American Florist*, 13 (1898), No. 515, p. 1106, fig. 1).—The author claims that the variegation lessens the ability to resist fungus attacks.

A disease of *Pinus monticola*, J. LAURIE (*Gard. Chron.*, 3. ser., 23 (1898), No. 591, p. 244).—Reports a disease of this American pine. It proved to be caused by *Peridermium pini*.

A new leaf disease of coffee, P. HENNINGS (*Ztschr. Trop. Landw.*, 1 (1897), No. 8; abs. in *Bot. Centbl.*, 73 (1898), No. 11, p. 410).—Notes are given on *Hemileia woodii*, a new fungus enemy of coffee in German East Africa.

Etiology of "Malsania" of *Corylus avellana*, U. BRIZI (*Atti R. Accad. Lincei, Rend.*, 6 (1897), II, pp. 227-231).

Notes on *Sporotrichum globuliferum*, TRABUT (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 4, pp. 359, 360).

Note on the distribution of *Pseudocommis vitis*, M. BÉLÈZE (*Bul. Soc. Mycol. France*, 14 (1898), No. 1, p. 27).—Notes its occurrence in *Scabiosa*, *Rumex*, *Teucrium*, *Acer*, *Glechoma*, *Verbena*, *Viola*, etc.

On the rôle of *Pseudocommis vitis* in the bulb disease of *Crocus* and diseases of the chestnut and palm, E. ROSE (*Bul. Soc. Mycol. France*, 14 (1898), No. 1, pp. 28-36).

Concerning *Exobasidium vitis* on grapes, V. PEGLION (*Bot. Ent. Agr. e Patol.*, 4 (1897), pp. 302-304).

The grape oïdium, L. DEGRULLY (*Prog. Agr. et Vit.*, 29 (1898), No. 14, pp. 417, 418, pl. 1).

Influence of fertilizers on the diseases and injuries of grapes, P. COSTE-FLORET (*Prog. Agr. et Vit.*, 29 (1898), No. 12, pp. 363-372).

Concerning the diseases of grapes in Baden during 1897, E. BEINLING (*Wchubl. Landw. Ver. Baden* (1898), Nos. 6, pp. 68, 69; 7, pp. 83-85).

What is the proper scientific name for black rot of grapes? E. ROSE (*Bul. Soc. Mycol. France*, 14 (1898), No. 1, pp. 24-26).—An extensive synonymy is given, from which the author concludes the name should be *Guignardia ampellicida*, as that name antedates all others by more than 12 years.

The black rot of grapes, A. PRUNET (*Prog. Agr. et Vit.*, 29 (1898), No. 14, pp. 426-433).—A report made to the Congress of Viticulturists.

The black rot in Aveyron in 1897, E. MAERRE (*Prog. Agr. et Vit.*, 29 (1898) No. 17, pp. 531-535).

On the treatment of black rot, G. HÉRON (*Prog. Agr. et Vit.*, 29 (1898), No. 17, pp. 528-531).

On the use of corrosive sublimate for the prevention of grape disease, A. CHEVALLIER (*Prog. Agr. et Vit.*, 29 (1898), No. 14, pp. 420, 421).

On the treatment of pourriture grise, L. DEGRULLY (*Prog. Agr. et Vit.*, 29 (1898), No. 16, p. 483).—A powder, consisting of steatite 92 per cent, sulphate of alumina 3 per cent, sulphate of lime 4 per cent, and sulphate of iron 1 per cent is described.

Concerning a corrosive sublimate fungicide, L. DEGRULLY (*Prog. Agr. et Vit.*, 29 (1898), No. 16, pp. 481-483).—A fungicide, consisting practically of 100 liters of water, 20 kg. salt, and 5 kg. corrosive sublimate, was sold in France during the past year at an extravagant price. Allowing for the market price of the salt and mercury, it is said that the water sold at 1.17 francs per liter. The extravagant claims for the fungicide are not substantiated, although it has considerable merit. It was sold under the name "Liquenr antiseptique agricole."

Preparation and application of fungicides, W. C. STURGIS (*Connecticut State Sta. Bul.* 125, pp. 16, figs. 70).—Directions are given for the preparation and application of the following fungicides: Copper-sulphate solution, Bordeaux mixture, Bordeaux mixture and Paris green, ammoniacal solution of copper carbonate, potassium sulphid, corrosive sublimate, and formalin. Various kinds of spraying apparatus are figured and described, the cost of the materials is given, and brief notes on when to spray.

ENTOMOLOGY.

Proceedings of the ninth annual meeting of the Association of Economic Entomologists (*U. S. Dept. Agr., Division of Entomology Bul. No. 9, n. ser.*, pp. 87).—The proceedings of the convention held at Detroit, August 12 and 13, 1897.

The present and future of applied entomology in America, F. M. Webster (pp. 5-15).—The presidential address, consisting of general remarks on the value of the meetings of the association, the work and position of the entomologist, and his relations to politics, etc.

*Additional observations on the parasites of *Orgyia leucostigma**, L. O. Howard (pp. 15-18).—These observations are in addition to those previously published by the author (*E. S. R.*, 9, p. 258). From 5,000 larvæ and pupæ of *Orgyia leucostigma*, collected in July, 1897, there issued the following species of parasites: *Tachina mella*, 220; *Frontina frenchii*, 355; *Euphorocera claripennis*, 464; *Exorista* sp., 13; *Helicobia helicis*, 4; *Phorocera* sp., 45; *Chalcis ovata*, 551; *Apanteles parorgyia*, 3; *Dibrachys boucheanus*, 10; total, 1,665. From the cocoons, 321 male moths and 764 female moths were obtained. One hundred and forty-six of the caterpillars or chrysalids died from a disease that the author calls black rot and 33 from another disease that he calls red rot. In percentages the results were as follows: Moths, 21.07; dipterous parasites, 22.02; hymenopterous parasites, 11.02; disease, 3.58; total, 57.69. This leaves about 2,000 chrysalids that died from some unknown cause. The mortality ratio was 79 as contrasted with 98.2 per cent at a corresponding time in 1896.

Temperature experiments as affecting received ideas on the hibernation of injurious insects, L. O. Howard (pp. 18-20).—According to the result of experiments extending over a period of two years a change from a temperature of about 18° F. to one of 40 or 50° and then back again to a lower temperature, is fatal.

Notes on certain species of Coleoptera that attack useful plants, F. H. Chittenden (pp. 20-25).—The following insects are noted: *Orsodachna atra*, on pear and cherry; grapevine colaspis (*Colaspis brunnea*), which has been found on beans, clover, Le Conte pears, potatoes, corn, tick trefoil, and the New Jersey tea plant (*Ceanothus americanus*); horse-radish ilea-beetle (*Phyllotreta armoracia*), which has been taken in Wisconsin and may travel eastward; *Psylliodes punctulata*, which is found on rhubarb in the District of Columbia; corn and grass feeding Chaetocnemas (*Chaetocnema pulicaria*, *C. confinis*, and *C. parcepunctata*), which have been found upon corn and *C. denticulata* in Maryland on barnyard grass; the locust leaf miner (*Odontota dorsalis*), the range of plants liable to be attacked by which seems large and which has been found feeding on red clover under locust trees, and also on the hog peanut (*Falcata comosa*); *Chelymorpha argus*, found on the sweet potato; *Epicauta trichrus*, also found on the sweet potato and on hedge bindweed (*Convolvulus sepium*), and in Illinois on the may weed (*Maruta* [*Anthemia*] *cotula*); false rose chafer (*Macrodactylus angustatus*), which seems to prefer the black or sour gum (*Nyssa multiflora*), chestnut (*Castanea dentata*), oak, particularly chestnut oak (*Quercus prinus* et al.) and sassafras, and has also been beaten from dogwood, hickory, and persimmon, but the leaves of these did not appear to be fed upon to any noticeable extent; and the potato-bud weevil (*Anthonomus nigrinus*), found on the eggplant in Maryland.

An experience with Paris green, T. D. A. Cockerell (p. 25).—The author notes that in the case of an application of Paris green to the peach, as a remedy against *Allorhina mutabilis*, the poison which entered over-ripe peaches passed into the circulation of the tree so as to affect neighboring branches injuriously.

The present status of the San José scale in Michigan, W. B. Barrows (pp. 27-30).—The scale occurs in the State in thirteen different localities. The introduction of the scale into Ottawa County is traced to stock received from New Jersey in 1890. As it winters in Ingham and Ottawa counties, it is thought very likely it will winter safely further north.

Vernacular names of insects, C. P. Gillette (pp. 32-34).—A list of common names is given with a view to improvement in orthography.

Notes on Cape of Good Hope insects, C. P. Lounsbury (pp. 34-38).—Among the insects noted as injurious in South Africa is the red-winged locust (*Aceridium purpuriferarum*), which has decreased in numbers from attacks of a fungus disease identified with *Empusa grylli*. Artificial propagation of the disease was tried, but owing to

unfavorable meteorological conditions was found to be a failure in most cases. The author also notes as injurious a pyralid moth (*Lorostege frustalis*), the peach maggot (*Ceratitis capitata*), a serious pest from a horticultural standpoint, attacking peaches, nectarines, guavas, oranges, and loquats; and the red scale (*Aspidiotus aurantii*), one of the worst foes of citrus growers, which was very injurious in nearly all parts of the colony last year. The scale has no important insect foes or enemies in the colony; the small ladybirds attacking it have little effect and the imported species, with the exception of one (*Orcus australasia*) have not survived. Fumigation has been successful. The pinid beetle (*Sitodrepa paucica*) was found attacking leather and binding of documents in colonial archives. *Phylloxera vastatrix* seems to be increasing, but so far as known no leaf-infesting form appears in that region.

A useful American scale insect, L. O. Howard (pp. 38-40).—It is noted that there occurs in the southwestern part of the United States, on the creosote bush, a light insect (*Cerococcus quercus*) that seems important on account of its commercial possibilities. Other species of the genus found in North America noted are *Tachardia mexicana*, *T. gemmifera*, *T. pustulata*, *T. fulgens*, and *T. cornuta*. The commercial importance of the Chinese and Japanese *Ericerus pela* and the Indian *Ceroplastes ceriferus* has already been established, and the species (*C. floridensis*) occurring in the South in the gall berry deserves notice as does also *Cerococcus quercus*, which has been recorded as feeding on *Quercus oblongifolia*, *Q. undulata*, and *Q. agrifolia*. Remarks are made on the chemical character of the wax secreted by this insect.

Insects of the year in Ohio, F. M. Webster and C. W. Mally (pp. 40-46).—Besides the periodical cicada (*Cicada septendecim*) and the chinch bug (*Blissus leucopterus*), there are noted the San José scale (*Aspidiotus perniciosus*), oyster-shell bark louse (*Mytilaspis pomorum*), Colorado potato beetle (*Doryphora 10-lineata*), asparagus beetle (*Crioceris asparagi*), cankerworm (*Anisopteryx cernata*), bollworm (*Heliothis armiger*), *Brachyrhynchus granulatus*, *Coriscus ferns* on *Leptoterna dolabrata* tarnished plant bug (*Lygus pratensis*), bagworm (*Thridopteryx ephemeraformis*) from which a tachinid (*Sturmia distincta*) was bred; common mealy bug (*Dactylopius alonidum*), which was observed to be preyed upon by the slug *Limax campestris*: *Allorhina nitida*, usually not abundant in Ohio, but reported as doing considerable injury in 1896 to tomatoes in the southern part of the State, also as being very abundant this year in the central part of the State; the tachinid (*Euphorocera claripennis*), which was reared from the larva of *Owlodasys unicoloris*; *Conotrachelus nenuphar*, from which four samples of *Sigalphus curculionis* were reared; an unknown species of Tyroglyphus found affecting walnuts and chestnuts; larvæ of *Papilio troilus*, the time of the emergence of the imago of which is noted; larvæ of *Oncetra distincta*, which during the present year did considerable damage to young plums,

grapes, and nursery rows at Troy: *Oberca bimaculata*, a larva of which was found boring in an apple twig and its method of work noted: *Hannamelis virginiana*, the larvæ of which were found similarly boring in a twig of witch-hazel; *Conotrachelus posticatus*, which was reared in great numbers from a lot of acorns of *Quercus alba*; and the grape-root worm (*Fidia viticida*), still a pest in the vineyards along Lake Erie, notwithstanding the increased numbers of parasites. An experiment with tobacco dust and kainit as remedies against this pest is noted, which showed that the kainit can scarcely be applied strong enough to be effectual.

On the preparation and use of arsenate of lead, A. H. Kirkland (pp. 46-49).—To make 10 lbs. of arsenate of lead in 150 gal. of water, as used in the work against the gypsy moth, there is required about 13 lbs. $2\frac{1}{2}$ oz. of acetate of lead and 5 lbs. $7\frac{2}{3}$ oz. of arsenate of soda. The relative amounts of these two salts must be governed by their purity. The best results are obtained by preparing the poison according to the method described in the paper read by the author at the last meeting (E. S. R., 9, p. 660). The method of weighing the salts in connection with the gypsy moth work is noted. The cost of the lead mixtures is about $6\frac{1}{2}$ cts. per pound, exclusive of freight, labor, boxing, etc., which latter factors it is thought should not increase the cost over $\frac{1}{2}$ ct. a pound. A 25-gal. galvanized iron tank has been found more convenient in woodlands than a larger one. To prevent clogging a strainer of wire gauze with 70 meshes to the inch is used, and for the same purpose a wire gauze strainer is inserted in the nozzle of the spraying apparatus. Arsenate of lead when applied to foliage in the form of a spray is shown to be very permanent. Even in unfavorable weather from 60 to 80 per cent of larvæ are destroyed. Three to four pounds of the mixture are equal in effect to 1 lb. of Paris green, but it is nevertheless a cheaper remedy. Another arsenate of lead, the diplumbic arsenate, has been prepared from nitrate of lead and arsenate of soda at a somewhat smaller cost than that noted for the arsenate of lead.

Notes on the malodorous carabid, Nomius pygmaeus, W. B. Barrows (pp. 49-53).—A very offensive odor was traced to this beetle.

Notes on insecticides, C. L. Marlatt (pp. 54-63).—Soaps, resin washes and compounds, pure kerosene, kerosene emulsion; the lime, salt, and sulphur wash; hydrocyanic-acid gas, steam and superheated water, arsenicals, and lime are discussed. No more unsatisfactory material for work against insects can be found than soft soap. The formulas often given are criticised as calling for too large an amount of water. Experiments have shown that an addition of 1 oz. of lime for each quart of diluted soap will render soap fluid when cold, even when in strong solution. Experiments in making a soap with potassium hydrate and oil are mentioned. For trees five years old and under 1 gal. of resin wash is thought sufficient per tree, while for trees twenty to thirty years old 6 or 8 gals. may be necessary. Several formulas are

mentioned. The objection is raised to the Webber and Swingle formula that there is a large amount of sediment. Pure kerosene was used on different trees without ill effects. The soil was mounded up at the base of the young trees to prevent the oil collecting at that point. On one large peach tree sprayed at least 99 per cent of the scales were killed. The remainder were protected by masses of leaves about the limbs. Identical results were obtained in spraying *Euonymus*. The experiments were performed when the trees were dormant. A manufacturing plant for kerosene emulsion in California is noted where the emulsion is made at a cost of 13 cts. per gallon in the undiluted state. When diluted the cost is a little over 1½ cts. per gallon.

The lime, salt, and sulphur wash seems to be less effective in northern California, where moist conditions prevail. Successful experiments are noted with hydrocyanic-acid gas on trees on the grounds of the Department of Agriculture.

Experiments with formic aldehyde gas produced no results. It is not worth considering in comparison with hydrocyanic-acid gas.

The bean leaf beetle, F. H. Chittenden (pp. 64-71).—It is noted that *Cerotoma trifurcata* has been found on beans in portions of Maryland and Virginia, and it is thought probable that the species is on the increase. A brief account of the literature is given, and of the insect's occurrence in 1897. The insect in its different stages is described. Its distribution is given from Canada southward to the Gulf States and westward to Kansas and Minnesota. It has been found attacking tick trefoil, hog peanuts, cowpeas, and beans. The beetles attack plants somewhat differently, sometimes attacking the edges of the leaves, as in the case of the hog peanut, sometimes even consuming the mid-rib. In the case of the bean and the cowpea they form large round holes in the leaves. As they feed on the under surface of the leaves and are at rest during the greater portion of the day they seldom attract attention; but on wild plants they are found in the center of the upper surface near the tops. The nature of their work is somewhat similar to that of the grapevine colaspis. The eggs are laid around the stem of the plant in clusters of from 6 to 10 and the larvae attack the plants at this point. In Minnesota the first generation is said to feed on beans and the second on cowpeas. In the District of Columbia it is thought that the period of egg deposition extends from the middle of May through June, and that the entire life cycle probably requires six to nine weeks. Spraying with arsenicals and clean culture are advised.

Notes on Anarsia lineatella, A. B. Cordley (pp 71-75).—The work of this insect in Oregon on peach and prune trees and strawberry plants is discussed. It is thought that two species must be involved in the description of *Anarsia lineatella*, or else a dimorphism due to food plants and seasons exists. One of the species it is thought feeds normally on strawberry plants, the other upon trees of the genus *Prunus*. It is thought that possibly one may be *Anarsia prunus*.

A successful lantern trap, C. P. Gillette (pp. 75, 76).—There is here described an apparatus of tin consisting of 3 pieces—a funnel 22 in. in diameter and 20 in. high, with a stem $2\frac{1}{2}$ in. in diameter which fits inside the neck of a reservoir which has a removable bottom. In the reservoir, which is 5 in. in diameter, is placed a quantity of excelsior and a 3-oz. wide-mouth cyanid bottle. In one night before 12 o'clock as many as 2,000 moths and 3,000 beetles, besides other insects, were taken in one of these traps hung under an electric light, and the majority of the specimens were uninjured.

Oviposition in young forest trees by Tetraopes femoratus, C. P. Gillette (pp. 76, 77).—The method of egg deposition by this insect, as observed by the author, is described. The insect, as watched, occupied one minute in cutting a cross slit and about nine minutes in depositing her eggs in it. Four such cuts were found on one petiole. Three contained two eggs each, the other, one. The insect does not confine its attacks to the soft maple nor to the petioles of leaves.

A few insects that have been unusually abundant in Colorado this year, C. P. Gillette (pp. 77-79).—There are noted the peach-twig borer (*Anarsia lineatella*), which probably reached Colorado from California; *Haltica punctipennis*, found abundant on grapevines and the red raspberry and to some extent on strawberry plants, and plant lice (*Hyalopterus pruni*, etc.), against which whale-oil soap in the proportion of 1 lb. to 8 gal. of water was found more effective than the ordinary kerosene emulsion. *Schizoneura americana* seems to be greatly increasing in Colorado. It begins its attacks at the opening of the first buds, and when the clusters of leaves reach a diameter of 3 to 5 in. they die and the lice migrate to other leaves, which they cause to turn yellow or reddish and to roll. This species has been severely attacked by the larvæ of *Syrphus americanus*. Another syrphid (*Eupeodes volucris*) was very destructive to *Hippodamia convergens*, more so than the common lady-bird.

Notes on insects of Norway and Sweden, W. M. Schüyen (pp. 79, 80).—The following common pests are noted: *Agriotes obscurus* and *Diacanthus aeneus*, *Agriotes lineatus*, *Oscinis frit*, *Chlorops pumilionis* (*tanipus*), *Cecidomyia destructor*, *Phyllopertha horticola*, *Oligotrophus alopecuri*, *Cleigastra* (*armillata*?), *Diacanthus aeneus*, *Tipula oleracea*, *Anthomyia brassicae*, *Silpha opaca*, *Pieris brassicae*, *Meligethes aeneus*, *Psila rosa*, *Tipula oleracea*, *Syromastes marginatus*, *Cetonia metallica*, *Adimonia tanacetii*, *Anthonomus pomorum*, *Carpocapsa pomonella*, *Phyllobius pyri*, *Phyllopertha horticola*, *Psylla mali*, *Aphis mali*, *Telephorus obscurus*, *Phytoptus pyri*, *Nematus ribesii* (*rentricosus*), *Zophodia convolutella*, *Typhlocyba rosea*, *Aphis rosea*, *Tetranychus telarius*, *Hylurgus piniperda*, *Lophyrus rufus*, *Bupalus piniarius*, *Cecidomyia brachyntera*, *Tetranychus* sp., *Orygia antiqua*, *Bombix rubi*, *Hyponometa variabilis*, *H. padi*, and *Apoderus coryli*.

Notes from Maryland on the principal injurious insects of the year, W. G. Johnson (pp. 80-82).—The following insects are noted: *Phyto-*

nomus punctatus, *Chalcocnema pulicaria*, *Epitrix cucumeris*, *E. parcula*, *Trichobaris trinotata*, *Sphinx (Protoparce) carolina*, *Aphis gossypii*, *A. brassicae*, *A. persicae-uiger*, *Myzus cerasi*, *Diabrotica vittata*, *Murgantia histrionica*, *Anthonomus signatus*, *Graphops marcessitus*, *Typophorus (Paria) caesus*, *Conotrachelus nenuphar*, and *Diplosis pyricora*. In the comments on the San José scale (*Aspidiotus perniciosus*) it is noted that in an orchard containing 28,311 trees 13,000 are now dead or dying. The partially mature insect has been found in large clusters on crab grass (*Panicum sanguinale*).

Notes on some little-known insects of economic importance, W. G. Johnson (pp. 83-85).—The following are noted: *Hydracia marginidens*, found boring into the main stems and larger branches of cosmos plants; *Pyrausta ferrugalis*, found injuring young tender lower leaves of tobacco in a hotbed; *Uranotes melinus*, found on beans; *Cerotoma trifurcata (C. camina)*, observed in a patch of wax and Lima beans; *Crambus caliginosellus*, which was very destructive during 1897 to young corn in several counties; *Tribolium madens*, found in mill products sent from the State of Washington; and *Aspidiotus forbesi*, which during the season has been found very abundant on young apple, pear, and cherry trees.

A list of the members of the association is appended.

Revision of the Tachinidæ of America north of Mexico, D. W. COQUILLET (U. S. Dept. Agr., Division of Entomology Bul. 7, tech. ser., pp. 151).—This, a purely technical taxonomic monograph, is so arranged as to be of great use to the student. The economic importance and the habits of the group are very briefly noted, and the 98 species of parasites, arranged alphabetically in connection with their proper hosts, are listed. This is followed by a list of the 169 hosts in alphabetical order, with mention of the species of the group parasitic upon them. The orders of the class Insecta are attacked in the proportions shown by the following figures: Hymenoptera, 12; Hemiptera, 1; Orthoptera, 4; Coleoptera, 17; and Lepidoptera, 136. *Leucania unipuncta* and *Orgyia leucostigma*, each with 7 species of parasites, are the two forms most severely attacked.

Following these lists is a brief explanation of the classification and of the terms employed. A long table of genera and a list of 34 unrecognized genera are given, introductory to the systematic arrangement of the genera and the description of species.

On the biology of *Ocneria dispar* in Russia, N. KULAGIN (*Illus. Wehenschr. Ent.*, 2 (1897), No. 27, pp. 418-420).—This pest appeared in great numbers in the government of Kostroma in 1895 and 1896. In 1894 and 1895 it appeared in great numbers along with *Ocneria monacha* in central Russia. The period of devastation generally lasted about three years, but in the region of Moscow it lasted four years (1893-1896). In 1895-96 in the government of Nijninogorod the moths appeared from July 8 to 18.

It was found that the eggs would stand a temperature of 40° R.

(122° F.), but when deprived of their covering were killed by 15° R. The larvæ appeared at the beginning of May and molted five times before pupation. Pupation occurred at Moscow July 2.

In some places in Vovonesch 20 per cent of the young eggs were killed. In many places the insects were severely parasitized. In Vladimir 40 per cent of the pupæ were so affected: in Moscow in 1895 20 per cent and in 1896 57 to 60 per cent. In Vovonesch in 1894 70 to 80 per cent were parasitized. In Moscow the parasites were mostly flies. At one place near Moscow 1½ to 2 pud (49 to 72 lbs.) of eggs were collected from one hectare. In Vladimir 76 pud (2,741 lbs.) were collected from 6,000 hectares (14,830 acres).

A remedy for trial in the destruction of the worm of the vine (Cochylis), J. DUFOUR (*Chron. Agr. Cant. Vaud, 10 (1897), No. 8, pp. 216-220*).—After mentioning the commonly used pyrethrum and the fluctuations in the supply of the same, the author considers the substitution of terebinthin for pyrethrum in mixtures. It is sufficient to dissolve 3 kilos of black soap in several liters of warm water, afterwards adding thereto cold water to make 100 liters, finally adding 2 liters of the essence of terebinthin. These 102 liters of solution will cost about 3½ francs—less by half than the cost of the pyrethrum. It is important that not more than 2 per cent of the terebinthin should be employed, lest it damage the grapes.

The following experiments are noted: (1) Soap, 2 per cent; terebinthin, 1 per cent. Worms treated by plunging bunches of grapes rapidly into the solution. Of 21 worms, 3 were killed, 3 injured. (2) Same solution with the addition of colophane. Of 8 worms, 3 were killed, 2 injured. (3) Black soap 3 per cent, terebinthin 2 per cent. Of 64 worms, 44 were killed and 10 injured. (4) Black soap 3 per cent, sulphurous terebinthin 2 per cent. Of 16 worms, 11 were killed. (5) Black soap 3 per cent, terebinthin 1 per cent, oil of colza 1 per cent. Of 33 worms, 20 were killed and 5 injured. Analogous results were obtained by replacing the terebinthin with benzin. (6) Soda, 3 per cent; terebinthin, 2 per cent, with and without the addition of blue vitriol 2 per cent. Many worms killed but grapes greatly damaged. (7) Black soap, 3 per cent; terebinthin, 3 per cent. Of 24 worms, 18 were killed and 5 injured. This last solution, it is noted, burned the grape bunches, the parts most sensitive to its action being not the flower but the small pedicel that supports it. A similar effect follows the use of the 2 per cent solution in a very slight degree, but this, it is thought, is greatly counterbalanced by the worms killed.

Contributions from the New Mexico Biological Station, No. 2, on the collection of Diptera from the lowlands of Rio Nautla, in the State of Vera Cruz, II, C. H. T. TOWNSEND (*Ann. Mag. Nat. Hist., 6. ser., 20 (1897), 115, pp. 19-31*).—A new Psychodid (*Psychoda punctatella*), a new Tabanid, several Syrphids, and two new Phasiids are described. The distinctive features of *Tabanus mericanus* and varieties are brought out tabularly, as are also the characters of several forms of the Syrphid genus *Nausigaster*. The author is confident that several species of this genus occur in North America, and three of them are described by Williston under the name of

Nansigaster punctulata. The author distinguishes the species from *N. punctulata* as follows:

(1) (a) A single spot on the wings; 5 thoracic vittæ; from California; *N. unimaculata* n. sp. (b) Spots on wings; the spots not confluent; only 2 thoracic vittæ; from New Mexico; *N. punctulata*, Will.

(2) The 2 wing spots confluent, forming a more or less well-defined and extensive picture, the basal cell mostly filled with the picture; 1 thoracic vittæ; habitat, Lowlands of Texas to Brazil; *N. meridionalis*, Towns.

(3) The second basal cell almost wholly hyaline. From the Texas lowlands; *N. germinata* n. sp.

Five new species of *Volucella* are distinguished from one another and *Williston's Chetophora* in the same manner. *Viridana* n. sp., is distinguished by the occurrence of a presutal row of bristles; its bright marked, green scutellum and copper abdomen; *Chetophora* by its hyaline wings with only a milk tinge in oblique lights; *Opalina* n. sp., by its metallic scutellum, which resembles the abdomen in color; the absence of stripes on the face and cheeks and of yellow on the abdomen, and by its wings being strongly shaded with brown; *Raphalana* n. sp., by its striped face and cheeks; *Codia* n. sp., by its brown yellow scutellum, the second abdominal segment resembling it and the rest of the abdomen being yellow; *Nautana* n. sp., by its second and third abdominal segments being of the same color as the scutellum, by a nearly equal subtriangular patch on the anterior corners, and by a similar easily distinguishable patch on the anterior corners of the fourth segment.

Report of the State entomologist for 1897, W. M. SCHÖYEN (*Christiania, 1898*, pp. 45, ill.).

Contribution to the knowledge of some of the gall-making insects of Vallombrosa, G. CECCONI (*Malpighia, 9 (1897)*, pp. 131-157).

Ants' nests, A. FOREL (*Internat. Jour. Micros. and Nat. Sci., 3, ser., 7 (1897)*, No. 36, pp. 347-381, pls. 2).—This is a translation of the author's "Die Nester der Ameisen" published at Zurich in 1893, and is an interesting discussion of the various forms of nests, the operation of building them, and other collateral questions such as symbiosis, the kindred relations between ants and plants, nests of mixed colonies, migratory nests, road building, etc.

On the attraction of flowers for insects, J. LUBBOCK (*Jour. Linn. Soc. Bot. London, 33 (1898)*, No. 231, pp. 270-278).—From the results of a series of tests the author maintains that both color and scent are instrumental in guiding and attracting honey bees. The experiments of Plateau are said to be inconclusive, many of them being conducted upon mutilated flowers with no checks. The author placed drops of honey on the bright blue bracts of *Eryngium amethystinum* as well as on the flowers, and both were visited indiscriminately. Solutions of sugar and saccharine were placed near by, and the first was visited, while the other did not attract a visitor.

The San José scale, H. OSBORN (*Iowa Sta. Bul. 36*, pp. 860-861, figs. 3).—As this insect does not occur in Iowa, this article, which is a brief popular account of it, the plants that attract it, etc., is intended as a warning notice to those concerned.

The woolly aphid of the apple, J. M. STEDMAN (*Missouri Sta. Rpt. 1897*, pp. 36-61, figs. 6).—A reprint of Bulletin 35 of the station (E. S. R., 9, p. 155).

The lesser apple leaf folder and the leaf crumpler, J. M. STEDMAN (*Missouri Sta. Rpt. 1897*, pp. 62-80, figs. 6).—A reprint of Bulletin 36 of the station (E. S. R., 9, p. 157).

Insect enemies of the locust, A. D. HOPKINS (*West Virginia Farm Review, 6 (1898)*, No. 3, pp. 88-93, figs. 6).—The author gives a popular description of and figures 3 principal enemies of this tree, namely, the locust leaf beetle, locust tree borer, and the carpenter worm. The unhealthy condition of the yellow and black locusts in the State has within recent years attracted considerable attention.

Termites, B. GRASSI and A. SANDIAS (*Quart. Jour. Micros. Sci. [London], n. ser., 40 (1897)*, 1, pp. 1-75; abs. in *Jour. Roy. Micros. Soc. [London], 1897*, No. 5, pp. 370-372).—

This is a translation by W. H. F. Blanford of Grassi's Italian memoir on the constitution and development of termite societies. The memoir is the result of a long series of observations on *Calotermes* and *Termes*. It is concluded that all the species of Termitidae belong to one of two main types of colonies, which are:

(1) A colony over which a king and queen preside. The king and queen once possessed two fully developed wings. When a colony is orphaned a pair of royal substitutes or neotenic forms are chosen.

(2) A colony with numerous neotenic queens and with neotenic kings, which are present for only short periods. This type of colony is not founded by the royal forms that govern it, but by detached portions of a preexisting colony.

Many fully winged insects leave the nests of these termites every year. Some of those of *Calotermes flaviculus* found new colonies, but under ordinary conditions those of *Termes lucifugus* are not able to do so, at least in Sicily. The males and females swarm separately, and consequently consanguineous mating is scarcely possible. After settling on decayed trees, the winged *Calotermes* get rid of their wings and begin to burrow; the sexes pair and each pair founds a fresh colony. Communication between the insects in both genera is by jerking convulsions of the whole body which produce sounds which seem to be heard by the insects, and members of the same nest recognize each other.

The Termitidae live on triturated, dead, or decayed wood particles mixed with saliva disgorged by their fellows, and their excrement. A colony of soldiers which can not gnaw wood soon dies of starvation, but a single large larva which is constantly burrowing can keep 8 or 10 soldiers alive on its excrement. Dead, diseased, or even healthy but superfluous individuals of the same species and the salivary secretions are also eaten. Water is sometimes imbibed, but not habitually.

By varying the quantity and proportion of nutriment the insects vary the forms in the colony, obtaining workers, soldiers, and neotenic forms. The neotenic forms are produced by the administration of large quantities of saliva, which gets rid of parasitic protozoa found within the alimentary canal. Newly hatched larvae receive nothing but saliva, while those destined to become workers or soldiers receive little or none.

Termes lucifugus often migrate from one tree to another, carrying eggs and young. Thus it sometimes happens that communication with the male colony is lost and they are compelled to form new colonies. In *Calotermes* strangers of the same species are received into the nest. If the colony is orphaned, even a royal pair may be so received. Jealousy among royal forms is less noticeable than in the case of bees.

Some notes on the parasites of *Orgyia leucostigma*, L. O. HOWARD (*Proc. Ent. Soc. Washington*, 4, No. 2, pp. 60-63).—In the discussion that followed the reading of this paper, an abstract only of which is given, B. E. Fernow mentioned that twenty years ago on the island of Rügen in the Baltic Sea an outbreak of *Orgyia pudibunda* occurred, during which the Government expended large sums in an endeavor to destroy the pest. During the progress of this work it was noticed that large numbers of parasites were issuing from the cocoons. Thereupon the work of destruction was stopped and the parasites given an opportunity to finish their work. The result was that next year they had practically exterminated the moth. Thus a large amount of money was saved.

W. T. Swingle referred to a case that came to his notice in Florida in which spraying with Bordeaux mixture resulted in killing a fungus parasite of the orange scale, in consequence of which the scale increased enormously.

W. B. Alwood noted that at Richmond, Virginia, an outbreak of *Goes pulverulenta* on the elm caused losses amounting to from \$15,000 to \$20,000.

Reports on the results and the cost of liming against the nonne in the Olbersdorf portion of the State Forest Reserve of Augustusburg, THEBEMANN (*Tharand. Forst. Jahrb.*, 47 (1897), No. 2, pp. 247-253).—The cost of labor is placed at 2 marks (57.6 cts.) for men, 1.08 marks (35.7 cts.) for women, and 60 pfennigs (14.3 cts.) for children. The entire cost of liming 9.32 hectares amounted to 325.01

marks (#77.32), or 34.87 marks (#8.30) per hectare. The cost for the collection of nun moths for three years is given as follows: 1894, 794 moths, 110.49 marks; cost per moth, 14 pfennigs; 1895, 701 moths, 137.12 marks; cost per moth, 20 pfennigs; 1896, 398 moths, 63.11 marks; cost per moth, 16 pfennigs. The average number of moths captured per hectare in the three years was 26, 33, and 19, respectively.

FOODS—ANIMAL PRODUCTION.

Comparison of the thermogenetic or dynamogenetic power of simple food stuffs with their nutritive value, A. CHAUVEAU (*Compt. Rend. Acad. Sci. Paris*, 125 (1897), No. 25, pp. 1070-1078, *dyms.* 2).—Three experiments with a dog made by the author's usual methods¹ are reported with but few details. In the first experiment the dog was fed a basal ration of meat to which isodynamic quantities of lard and sugar (1:2.373) were added in different periods. The quantities fed were—meat 100 gm., lard 51 gm., and sugar 121 gm.

In the second experiment to a basal ration of meat, fat (lard) and sugar were added in different periods in quantities intermediate between their isodynamic and isoglycogenetic values; that is, in the ratio of 1:1.83. The amounts fed were—meat 500 gm., lard 110 gm., and sugar 200 gm.

In the third experiment to a basal ration of 500 gm. meat was added 110 gm. fat or 168 gm. sugar; that is, the amounts of sugar and fat were proportional to their isoglycogenetic values (the amount of glycogen which could be formed from each). In all the experiments some muscular work was performed.

Among the conclusions reached were the following: The heat of combustion (often assumed to represent the real nutritive value) of sugar and fat is not the measure of the energy which the two substances furnish for the production of force in the animal body. There is a considerable discrepancy between the two values. If the heat of combustion of cane sugar is 1, that of fat is 1.52, and not 2.373, the isodynamic value ordinarily assumed. On the other hand, sugars and fat possess the same nutritive value when consumed in quantities proportional to the amount of glycogen which they can form. Thus, 1.52 gm. of cane sugar or 1 gm. of fat yields 1.61 gm. of glycogen, in the one case by hydration and in the other by oxidation. The different nutrients are not directly sources of potential energy, i. e., of energy in the working muscle. Glycogen alone (which permeates the muscles) can be regarded as the source of muscular work. It is continually used up and renewed and equilibrium maintained.

It is needless to remark on the importance of the bearing of these deductions on the value of sugar as a nutrient.

¹The author has devised a respiration apparatus which permits the measurement of the inspired and respired air and a determination of the respiratory quotient. The respiratory movements are also recorded graphically. The amount of muscular work performed may be measured.—*Arch. Physiol. Norm. et Path.*, 5. ser., 8 (1896), pp. 563-571.

The importance of asparagin for animal nutrition, M. CHOMSKY (*Ber. Physiol. Lab. Landw. Inst. Halle, 13, pp. 1-12*).—To study the nutritive value of asparagin an experiment divided into five periods was made with a Southdown sheep. The periods were all of eight days' duration, except the fourth, which was seven days. In the first period the animal was fed a normal ration, which contained as little nonalbuminoid nitrogen as possible. For this purpose oat straw and sesame cake were selected. In the second period the ration contained the same amount of nitrogen-free material, but the amount of protein was diminished. In the third period the ration was the same as in the second period, except that asparagin was substituted for the protein omitted. In the fourth period, the ration was made up of the same ingredients as in the first period but contained a larger quantity of protein. In the fifth period the ration was the same as in the fourth, except that part of the protein was omitted and an equivalent amount of asparagin substituted for it. The food, urine, and feces were analyzed. The results of the experiment are reported in full and are summarized in the following table:

Results of sheep feeding experiment.

Period.	Ration: 600 gm. oat straw, 240 gm. potato starch, and —	Coefficients of digestibility.					Nitrogen in—			Gain (+) or loss (—) of nitro- gen.
		Dry matter	Pro- tein.	Fat.	Crude fiber.	Nitro- gen- free ex- tract.	Food.	Urine.	Feces.	
		Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Gm.	Gm.	Gm.	Gm.
1	150 gm. sesame cake, 102 gm. cane sugar.....	59.62	57.62	57.69	44.25	72.15	12.01	4.61	5.09	+2.31
2	75 gm. sesame cake, 111.6 gm. cane sugar, 7 cc. sesame oil.	51.94	26.57	58.68	35.04	65.40	6.95	1.96	5.10	—0.11
3	75 gm. sesame cake, 111.6 gm. cane sugar, 24.45 gm. aspar- agin, 7 cc. sesame oil.....	57.17	51.27	62.27	40.12	70.57	11.51	4.26	5.61	+1.64
4	150 gm. sesame cake, 75 gm. fat-free sesame cake, 102 gm. cane sugar.....	59.85	62.15	62.89	45.40	71.80	17.08	7.97	6.46	+2.65
5	150 gm. sesame cake, 102 gm. cane sugar, 24.45 gm. as- paragin.....	61.00	66.25	61.39	48.49	71.39	16.58	9.46	5.59	+1.53

At the beginning of the test the sheep weighed 42.4 kg. During the first period he gained 1.7 kg., during the second period his weight remained unchanged, during the third period the gain was 1 kg., and during the fourth and fifth periods 0.9 kg.

In the author's opinion the experiment shows that asparagin can take the place of protein only when combined with carbohydrates; that is, when it forms part of a normal ration or one containing an amount of carbohydrates greater than necessary. Asparagin does not simply improve the digestibility of carbohydrates, but exercises a definite function which is different from that of carbohydrates.

The author also reports an experiment with the same sheep in which amid nitrogen was substituted for protein. The amid nitrogen was supplied in the form of beets. The ration consisted of 600 gm. of oat

straw, 3,500 gm. of beets, and 11 cc. of sesame oil. According to the author's analysis, this furnished 27.43 gm. of true protein, 13.72 gm. of amids, and 9.10 gm. of nitrates. The test lasted 8 days. The daily nitrogen balance was as follows: In food 7.72 gm., in urine 2.77 gm., in feces 4.02 gm.: gain, 0.93 gm. The coefficients of digestibility were: Dry matter 55 per cent, protein 47.9 per cent, fat 53.1 per cent, crude fiber 34.9 per cent, and nitrogen-free extract 66.3 per cent. The sheep gained 0.5 kg. in weight during the eight days. In the author's opinion this test does not warrant general deductions.

The work of other investigators with asparagin is reviewed at length and many experiments quoted in detail.

Examination of Swedish fodder plants, IV, A. G. KELLGREN and L. F. NILSON (*K. Landt. Akad. Handl. Tidskr., 36 (1897), No. 5, pp. 299-370*).—In continuation of work previously reported (*E. S. R., 4, pp. 768, 971; 7, p. 497*) the authors give the results of a study of the economic flora of Sweden, especially of the northern regions. Analyses are reported of 6 samples of grasses, 16 of Cyperacea, 25 of Leguminosae, and 6 of miscellaneous plants. The investigation includes a comparison of *Trifolium pratense* grown from native seed and seed from a number of countries. In the following table is given the composition of a number of the feeding stuffs. The greater number of them were grown at the experiment station at Albano (near Stockholm).

Composition of Swedish fodder plants.

Name of variety.	Water.	Protein.	Ether extract.	Crude fiber.	Nitrogen-free extract.	Mineral matter.	Total nitrogen.	Digestible nitrogen in total.	Amid nitrogen in total.

The cooking of meat (*Rev. Gén. Sci. Pures et Appl.*, 8 (1897), No. 19, p. 766).—A brief summary is given of experiments by G. Fiore¹ and E. Vallin² on the temperature of the interior of meat cooked in different ways. Fiore measured the temperature by inserting bits of metal, whose temperature of fusing was known, into the interior of pieces of meat. Pieces of meat were also inoculated on the surface and interior with a solution rich in the spores and bacilli of charbon. After cooking the meat in various ways guinea pigs were inoculated with the meat juice. It was found that prolonged broiling was the most satisfactory method for destroying the bacilli and the spores. The broiling, roasting, and brazing practiced were not entirely satisfactory.

Vallin tested the temperature of different parts of the meat by the introduction of capillary tubes containing chemical substances whose melting point was known. In general his conclusions were the same as those cited above. He calls attention to the fallacy of the popular opinion that rare meat is more nutritious and digestible than well-cooked meat.

Pig-feeding experiments, J. KLEIN (*Milch Ztg.*, 26 (1897), Nos. 8, pp. 114-116; 9, pp. 130-133).—The author reports experiments made at the Dairy Institute at Proskau in 1896 to study the nutritive value of skim milk, beans, peas, whey, and potatoes. The eight pigs used were divided into four lots, each lot including a boar and a sow. The test, which began July 15 and continued twenty-four weeks, was divided into four periods of 35, 42, 42, and 49 days, respectively. Lot 1 was fed skim milk, whey *ad libitum*, potatoes, and beans; lot 2 received the same ration as lot 1 except that peas were substituted for beans; lot 3 had the same ration as lot 1 except that the quantity of beans was decreased one-half and the quantity of skim milk proportionately increased; lot 4 received the same ration as lot 1 except that half as much whey was fed and a proportionately larger amount of potatoes.

It was assumed that 1 kg. of skim milk was equivalent to 120 gm. of beans and that 3.2 kg. of whey was equivalent to 1 kg. of potatoes. A slop was made of the different feeding stuffs, the beans or peas being first soaked and the potatoes cooked and mashed. In the early part of the test the milk and whey were fed warm.

For four weeks before the beginning of the test proper the pigs ate 628.25 kg. of skim milk, 157 kg. of whey, and 47.5 kg. of potatoes and gained 37.5 kg. in weight.

One of the pigs in lot 2 was sick and was dropped at the end of the second period.

¹ Ann. Ig. Sper., 1897, No. 1, p. 21.

² Rev. Hyg. et Police Sanitaire, 1897, No. 9.

A detailed statement is given of the gains made during the test proper. The average results were as follows:

Results of pig feeding.

	Length of test.	Food consumed.					Gain in weight.
		Skim milk.	Whey.	Potatoes.	Beans.	Peas.	
	<i>Days.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>
Lot 1.....	168	427	1 897	896	126.0	148.5
Lot 2.....	77	343	483	196	37.8	48.5
Lot 3.....	168	931	1 897	896	65.3	151.5
Lot 4.....	168	427	987	1,176	126.0	144.0

The rations fed to lots 1, 3, and 4 were regarded as of practically the same value. In the author's opinion the assumption was warranted that skim milk could be substituted for beans and whey for potatoes in the proportions mentioned above.

The pigs were slaughtered after the conclusion of the test, and the live weight and dressed weight were recorded as well as the thickness of the bacon and the amount of belly fat.

Pig-feeding experiments, J. KLEIN (*Milch Ztg.*, 26 (1897), Nos. 51, pp. 807, 808; 52, pp. 824-827).—In continuation of the work reported above the author made experiments with pigs in 1897. Eight Meisen-Yorkshire boars were divided into four lots of two each. Lot 1 was fed skim milk, barley, and potatoes; lot 2 the same ration as lot 1, except that whey was substituted for skim milk; lot 3 the same ration as lot 1, with soaked peas substituted for part of the skim milk; and lot 4 the same ration as lot 3, except that the peas were cooked.

The test proper began May 17 and continued twenty-two weeks. It was divided into three periods of 42, 42, and 70 days. During the four weeks before the beginning of the test proper the pigs consumed 840 kg. of skim milk, 56 kg. of barley, and 140 kg. of potatoes, and made a total gain of 73.25 kg. The food consumed and the gains made during the test proper are recorded in full.

The third period with lot 3 covered only forty two days. In order that a comparison may be made between lots 3 and 4 the food consumed and gains made by lot 4 during the same length of time are included in the following table, which shows the average results for the 4 lots:

Results of feeding pigs.

	Length of experiment.	Food consumed.					Gain in weight.
		Skim milk.	Barley.	Potatoes.	Whey.	Peas.	
		<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	
Lot 1.....	154	1,309	480.9	472.5	166.50
Lot 2.....	154	574	480.9	472.5	980	172.50
Lot 3.....	126	504	372.4	364	73.5	145.00
Lot 4.....	154	574	480.9	472.5	94.5	173.75
Do.....	126	504	372.4	364	73.5	147.90

In the first period the nutritive ratio of the rations fed to the four lots and the corresponding gains made were—Lot 1, 1:5.3, 21.38 kg.; lot 2, 1:6.2, 22.63 kg.; lot 3, 1:5.3, 23 kg.; lot 4, 1:5.3, 24.13 kg. In the second period the corresponding figures were—Lot 1, 1:5.56, 26 kg.; lot 2, 1:6.6, 26.75 kg.; lot 3, 1:5.8, 26.38 kg.; lot 4, 1:5.8, 26.13 kg.; and in the third period, lot 1, 1:6.1, 35.88 kg.; lot 2, 1:1.73, 36.88 kg.; lot 4, 1:6.6, 36.13 kg.

In every case the greatest gains were made on the ration with the widest nutritive ratio. One kilogram of skim milk was found to be equivalent to 125 gm. of peas. In the author's opinion the cooked peas were to be preferred to the soaked peas.

At the conclusion of the test the pigs were slaughtered. Data are given concerning the live weight, dressed weight, thickness of belly fat, and bacon. The percentage of water, iodine value, melting point, and viscosity of the fat were determined. The test is discussed at some length from a financial standpoint. Substituting whey for part of the skim milk in lot 2 effected a saving of \$2.40, estimating skim milk at 0.6 ct. and whey at 0.15 ct. per kilogram. It was calculated that 1 kg. of skim milk gave a return of 1.152 cts.

Horse feeding: Tests of the digestibility of oats, hay, and the "new corn product," H. J. PATTERSON (*Maryland Sta. Bul.* 51, pp. 46).—Tests were made with two horses weighing about 850 and 950 lbs., respectively, to determine the digestibility of timothy hay, oats (whole and ground), shelled corn, corn meal, and the "new corn product." The new corn product is prepared by grinding cornstalks, from which the blades, husks, and pith have been removed, into meal which in general appearance resembles coarse bran, dried malt sprouts, or brewers' grain.

The digestion experiments were usually of fourteen days' duration, nine days being regarded as a preliminary period. Analyses were made of the food and feces, and the nitrogen in the urine was determined (except in the test with ground oats), thus giving data for the study of the metabolism of nitrogen. The digestibility of timothy hay was first determined. In the rations in which hay was fed with other materials the amount of hay digested was deducted from the total amount digested in determining the coefficient of digestibility of the other materials.

In one instance the horses were fed a mixed ration containing no coarse fodder except the new corn product. It was made up as follows: New corn product 50 per cent; hominy chop, ground oats, ground rye, and linseed meal each 10 per cent; and gluten meal and wheat bran each 5 per cent. In the author's opinion such a ration possesses an advantage over ordinary rations, as all the ingredients, including the coarse fodder, can be mixed together.

The coefficients of digestibility in the different experiments are shown in the following table:

Coefficients of digestibility of rations fed to horses.

	Dry substance.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>

The following table shows the food consumed per day and the average income and outgo of nitrogen:

Income and outgo of nitrogen in experiments with horses.

	Food consumed per day.	Duration of experiment.	Nitrogen in food.	Nitrogen in urine.	Nitrogen in feces.	Gain (+) or loss (-).
		<i>Days.</i>	<i>Gm.</i>	<i>Gm.</i>	<i>Gm.</i>	<i>Gm.</i>
Horse 1....	5,143 gm. timothy hay.....	7	36.6	36.7	27.8	-27.9
Horse 2....	6,000 gm. timothy hay.....	5	42.7	33.1	34.9	-25.3
Horse 1....	2,186 gm. timothy hay, 6,000 gm. whole oats.	5	134.8	67.9	26.2	+40.7
Horse 2....	3,278 gm. timothy hay, 6,000 gm. whole oats.	5	142.6	74.9	37.9	+29.8
Horse 1....	3,000 gm. timothy hay, 3,000 gm. shelled corn.	5	62.3	26.5	26.1	+9.7
Horse 2....	do do.....	5	62.3	22.7	42.1	-2.5
Horse 1....	3,000 gm. timothy hay, 2,870 gm. corn meal.	5	64.0	16.5	26.0	+21.5
Horse 2....	3,000 gm. timothy hay, 3,500 gm. corn meal.	5	73.3	38.7	31.9	+3.7
Horse 1....	2,950 gm. new corn product, 2,950 gm. ground oats.	5	93.3	31.4	20.9	+41.0
Horse 2....	3,350 gm. new corn product, 3,350 gm. ground oats.	5	105.9	54.2	24.0	+27.7
Horse 1....	6,000 gm. mixed ration, including new corn product.	5	103.9	47.2	24.8	+51.9
Horse 2....	7,500 gm. mixed ration, including new corn product.	5	154.9	74.8	32.1	48.0

In every case the total amount of food consumed, the water drunk, and the weight of the horses at the beginning and end of the experiment are recorded.

An attempt was also made to feed the horses on oats alone. At the beginning of the trial one horse consumed 6,000 gm. and the other 6,750 gm. of oats per day, but after a few days refused to eat. The experiment could not be continued long enough to permit the determination of the coefficients of digestibility.

The author's conclusions are summarized as follows:

- “(1) Timothy hay proved to be less digestible by horses than by ruminants.
- “(2) Grinding oats increased their digestibility.
- “(3) Corn meal was considerably more digestible than shelled corn.
- “(4) Feeding concentrated foods or grain with hay decreased the digestibility of the hay.
- “(5) It is impossible to maintain horses on a grain ration alone; they must have a long forage.
- “(6) Making a ‘mixed feed,’ of the grain and long forage is the best manner of feeding horses.
- “(7) The new corn product was better digested by horses than timothy hay.
- “(8) Grinding fodder to the condition of the new corn product or of coarse bran does not destroy its value as long forage.”

Several tests were made of the value of the new corn product as a substitute for hay under various conditions of work. In the author's opinion, those who attempt to feed this material for the first time should gradually accustom the horses to it before substituting it entirely for hay. He believes it may be successfully used as a hay substitute.

Poultry experiments, J. DRYDEN (*Utah Sta. Bul. 51, pp. 33, pls. 1*).—In the winter of 1896–97 feeding tests were made with nine lots of chickens to test the influence of age, breed, and exercise on the amount and cost of egg production. In addition, the relative fertility of eggs under different treatments and the relative value of two incubators was also tested.

Lots 1 to 8, inclusive, were made up of 4 chickens each, and lot 9 of 5 chickens. Lots 1 to 6 were Rose-Comb Leghorns, lot 7 Brahma-Leghorn pullets, lot 8 Light Brahma pullets, and lot 9 Barred Plymouth Rock pullets. Lots 1 and 5 were old hens, lots 2 and 6 late hatched pullets, and lots 3 and 4 early hatched pullets. Lots 1 to 3 had no exercise; they were fed grain from boxes. Lots 4 to 9 had exercise, the grain fed being scattered in straw litter. In other respects all the lots were treated alike. The food consisted of a mash of bran and shorts, chopped corn, and oats, 2:1:1, fed in the morning with a little whole grain (a mixture of wheat, corn, oats, and barley). The corn was fed sparingly and the barley was discontinued after a short time, since it was not relished by the chickens. In the evening whole grain only was fed. The chickens were usually given cut meat and bones three times a week, and were supplied with cabbage or other green food. Occasionally they were given a little cayenne pepper during the winter, and they had access to coal ashes and gravel.

The results of the feeding tests are summarized in the following table:

Results of feeding tests with chickens.

Lot.		Cost of food.	Number of eggs laid.	Value of eggs.	Cost of food per dozen eggs.	Average weight of eggs per dozen.	Average weight of eggs per year per fowl.
WITHOUT EXERCISE.							
1	Old hens	53½	64	\$0.56	9.9	1.57	8.4
2	Late hatched pullets	56½	137½	1.32	4.9	1.40	15.98
3	Early hatched pullets	61½	157½	1.68	4.6	1.49	19.51
WITH EXERCISE.							
4	Early hatched pullets	62	181½	1.88	4.1	1.42	21.46
5	Old hens	62	106½	1.00	6.9	1.52	13.54
6	Late hatched pullets	63	150½	1.51	5.0	1.39	17.42
7	Brahma-Leghorn pullets	73½	145	1.47	6.1	1.52	18.39
8	Light Brahma pullets	81½	147½	1.40	6.6	1.63	20.03
9	Barred Plymouth Rock pullets	63	79½	.79	9.1	1.48	9.8

The principal conclusions reached were the following: The profit in feeding young hens or pullets was six times as great as in the case of hens three or four years old. Early hatched Leghorn pullets gave better results than those hatched later. The chickens which had exercise consumed more food and produced more eggs at less cost than those which had no exercise. Exercise had no apparent effect on the weight of the chickens. However, the eggs produced by the chickens having no exercise weighed 3 per cent more than those produced by the chickens having exercise. The eggs of the Leghorn hens weighed more than those of the Leghorn pullets, and those of the Light Brahma pullets more than those of the Leghorn pullets. The eggs of the Barred Plymouth Rock pullets averaged about the same as those of the Leghorn pullets. In the author's opinion, with intelligent care and feeding the average capacity of a Leghorn pullet is 200 eggs per year. No advantage was observed in crossing Brahmas and Leghorns.

A trial of two different incubators was made. This included a comparison of the relative fertility of old, medium, and fresh eggs of the different lots of chickens mentioned above. The data were not regarded as sufficient for drawing definite deductions concerning the incubators. Exercise apparently reduced the percentage of fertility of the eggs. The percentage of fertility was highest with eggs from early hatched pullets and lowest with eggs from old hens, though the results are not regarded as conclusive. The fertility of eggs averaging five days' old was 300 per cent greater than eggs averaging twenty-two days' old.

The bread of Italian peasants, R. CASTELANI (*Ann. Ig. Sper., n. ser., 6 (1896), No. 1, pp. 89-110*).—The composition is reported of bread made from wheat, corn, rye, barley, oats, millet, rice, legumes, potatoes, acorns, and chestnuts. These materials were used alone or in different combinations. The samples of bread were gathered from different provinces.

Chemical composition of several sorts of flour used in Belgium, LECOQ (*Bul. Assoc. Belge Chim.*, 10 (1896), p. 316; *abs. in Ztschr. Angew. Chem.*, 1898, No. 14, p. 326).—The maximum, minimum, and average protein, fat, ash, and water in several sorts of fine wheat flour are recorded. When the figures for ash and protein were unusual, the starch and cellulose were also determined.

A Soudanese cereal (*Gard. Chron.*, 3, ser., 23 (1898), No. 590, p. 232).—An editorial note on the use of *Paspalum longiflorum* in Soudan. This grain has the following percentage composition: Water 9.20, protein 7.67, fat 5.34, starch and dextrin 77.33, crude fiber 2.56, undetermined 3.90. For purposes of comparison the analyses of other cereals are given.

A study of the constitution of the gluten of different cereals; the influence of this factor on the value of flour for bread making, E. FLEURENT (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 64-70).

Average analyses of Danish concentrated cattle foods, V. STEIN (*Holt's Lommebog Landm.*, 1898, p. 67).

The carbohydrates of barley and malt, A. R. RING (*Gaz. Brasseur.*, 1898, Nos. 537 and 538).

Contribution to the study of maize diet, G. PANEGROSSI (*Ann. Ig. Specr.*, n. ser., 6 (1896), No. 3 pp. 293-350).—A number of experiments with a man are reported on the digestibility of Italian flour of different grades as compared with flour ground by Sheppard's process and with maize ground by Sheppard's process and by the ordinary method. In every case the food consisted entirely of the material tested prepared in the form of cake and porridge or mash. The food and feces were analyzed and the nitrogen in the urine was determined.

Experiments on the nutritive value of bread made from old-process and roller-process flour, L. BOUTROUX and A. BOUTROUX (*Ann. Hyg. Pub. et Méd. Légale*, 3, ser., 35 (1896), pp. 336-345).—Experiments are reported in which white mice were fed bread made from old-process and roller-process flour. The amounts consumed and the gains and losses in weight are recorded. The mice consumed larger quantities of the bread made from old-process flour and utilized it more completely as shown by the gains in weight. The flours were of about equal fineness and had the same gluten content.

The value of the two flours for man is discussed at some length and experiments of other investigators cited.

Hygienic measures in the expedition to Madagascar, J. LÉMURE (*Ann. Hyg. Pub. et Méd. Légale*, 3, ser., 35 (1896), pp. 233-242).—In addition to other matter the author discusses the food and water supply of the French troops in Madagascar. The rations prescribed by the Minister of War are quoted in some detail.

A new investigation on the digestibility of eggs, especially of egg albumin, JORISSENNE (*Jour. Hyg.*, 23 (1898), Nos. 1121, pp. 131, 132; 1122, pp. 143, 144).—The author has condensed the conclusions drawn from an extended investigation, the details of which are not quoted. The subject is treated chiefly from a medical standpoint.

Composition of meat peptones, PY (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 5-8).

The pentosans in different feeding stuffs with some considerations on vegetable chemistry and the analysis of fodders, MENOZZI (*2. Congrès Internat. Chim. Appl.*, 1896, II, pp. 251-255).—The pentosan content of *Boletus edulis*, mulberry leaves, silkworm excrement, and a number of feeding stuffs used in Lombardy is reported. No pentosans were found in *Penicillium glaucum* grown on gelatin.

Can vinegar from alcohol be legally sold under the name of vinegar? Investigation of artificial vinegars. Percentage of reducing substances, S. DE RACKOWSKI (*2. Congrès Internat. Chim. Appl.*, 1896, IV, pp. 250-260).

Coffee, PY (*2. Congrès Internat. Chim. Appl.*, 1896, IV, pp. 320-336, pls. 7).—Coffee

and coffee adulterants are described, especial attention being given to microscopical characteristics and chemical composition.

The detection of artificially colored coffee, G. MORPURGO (*Rev. Internat. Falsif.*, 11 (1898), No. 1, p. 27; *abs. in Ztschr. Angew. Chem.*, 1898, No. 11, p. 325).

Determination of tannic acid in coffee, TRILLICH and GÖCKEL (*Ztschr. Nahr. Untersuch. u. Hyg.*, 12 (1898), p. 101; *abs. in Ztschr. Angew. Chem.*, 1898, No. 11, p. 326).

Relation between the properties of different kinds of tea and the caffeine content of tea, L. GRAF (*Rev. Internat. Falsif.*, 11 (1898), No. 1, p. 20; *abs. in Ztschr. Angew. Chem.*, 1898, No. 11, p. 326).

The detection of corn flour and the adulteration of wheat flour, C. V. SMITH (*Health Mag.*, 5, No. 10, pp. 285, 286).—The author recommends the following as a simple test for the adulteration of flour with corn flour: Treat a small sample with a 50 per cent solution of acetic acid, making a very thin smooth paste; allow it to stand fifteen minutes; spread on a microscope slide on a thin film and examine with a two-thirds or three-fourths objective while moist. Wheat starch grains are unchanged. Corn starch grains take on a characteristic color.

Sophistication and adulteration of preserved food, DURAND and X. ROQUES (*2. Congrès Internat. Chim. Appl.*, 1896, IV, pp. 190-199).

Investigation by the Société Française d'Hygiène of the sanitary condition of the food supply of Paris (*Jour. Hyg.*, 23 (1898), Nos. 112, pp. 130-143; 1123, pp. 151-155).—As a result of investigation the society recommends the proper inspection of bakeries, kitchens, restaurants, and other places where food is prepared, both for the benefit of the public and of the employees.

The formation of fat in the body in phosphorus poisoning, O. POLIMANTI (*Arch. Physiol. [Pflüger]*, 70, No. 7-8, pp. 349-365).—A number of experiments (with suitable control tests) were made with frogs poisoned with phosphorus. In some cases the frogs were killed, in others the experiments continued until the frogs given phosphorus died. The livers were especially examined. Their fat content was determined by the Dormeyer method (digesting with pepsin and hydrochloric acid and extracting with ether). Those of the frogs given phosphorus had the appearance of bacon.

The author concludes that his experiments show the formation of fat from protein in cases of phosphorus poisoning, and further, that the central nervous system is not concerned in the changes brought about by the phosphorus. In addition to the increase in fat there is also an increase in the water content of the body.

Contribution to the physiology of the formation of fat and glycogen and phosphorus poisoning, E. PFLÜGER and J. ATHANASIU (*Arch. Physiol. [Pflüger]*, 71, No. 5-6, pp. 318, 322).—This is a controversial article. The authors do not agree with the conclusions of O. Colosanti concerning the formation of fat from protein in phosphorus poisoning.

Formation of fat from protein in cats, M. CRAMER (*München. Med. Wchnschr.*, 44 (1897), No. 29, p. 411).—The author reports briefly some of his experiments with cats on the possibility of the formation of fat from protein. The food, urine, feces, and gaseous excretory products were analyzed. A respiration apparatus was employed for the measurement of the respired air. In a test when the subject fasted it was calculated that 7.3 gm. of carbon must have been derived from the cleavage of protein of body tissue. A test in which the subject was fed an abundance of meat is also referred to, though fewer details are given.

The author concludes that his results confirm Voit's theory of the formation of fat from protein.

The influence of antiseptics on the digestion of blood fibrin by pepsin in a hydrochloric acid solution, C. F. MABERY and L. GOLDSMITH (*Jour. Amer. Chem. Soc.*, 19 (1897), No. 11, pp. 889-894).—Experiments were made to determine the effect

of alum, salicylic acid, boric acid, and formalin on the digestion of blood fibrin by hydrochloric acid and pepsin. Tests were also made to determine the effect of alum baking powder upon the digestibility of bread. It was found that even small amounts of alum decreased the digestibility and this effect increased markedly when large quantities were used. Boric acid decreased digestibility but the effect did not seem to be regularly dependent upon the quantity of acid used. Formalin diminished digestibility somewhat more than boric acid and the effect increased with increased quantities of the antiseptic. The effect of alum was more marked than that of either of the other substances.

The formation of gas in pancreatic digestion, F. KLUG (*Arch. Physiol. [Pflüger]*, 70, No. 7-8, pp. 329-345).—The author reports a number of artificial digestion experiments from which the following conclusions were drawn: It is extremely probable that when fat undergoes digestion there is cleavage not only to fatty acids, glycerin, and soaps, but also a deeper cleavage resulting in carbon dioxid and hydrogen as final products. This suggests the effect of trypsin on albumen. The primary products are albumoses and peptones, but by continued action leucin, tyrosin, and glutamic acid are formed. As in the case of albumen the cleavage of fat may be more complete than is profitable for the body.

Experimental investigations on the effect of copper on animals and its absorption and excretion, J. BRANDL (*Arch. K. Gesundheitsamte*, 13 (1896), No. 1, pp. 101-136).—Experiments were made with dogs and rabbits in which various copper compounds were injected into the circulatory system or taken into the stomach. Among the conclusions reached were the following: The effect of copper is most marked in the case of salts that are easily absorbed. When copper salts are taken into the stomach the poisonous action is affected by the contents of the stomach and intestines. Compounds of copper albuminates have less effect than salts since only a small portion is absorbed and a still smaller portion is taken up into the general circulation. Only small amounts of copper are excreted by the epithelia cells of the intestines and in the urine. Very little is found in the saliva and milk. On the other hand, copper is excreted slowly but continuously through the gall and is seldom stored up in any perceptible quantity.

Influence of alcohol on muscular work, E. DESTREE (*Rev. Sci. [Paris]*, 4. ser., 9 (1898), No. 17, p. 536).—A brief note on experiments in which a dynamometer was used. This showed, in the author's opinion, that alcohol first increased muscular work and then diminished it.

Determination of the coefficient of oxidation of nitrogenous material, L. MONFET (*2. Congrès Internat. Chim. Appl.*, 1896, IV, p. 70).—By coefficient of oxidation of nitrogenous material is meant the ratio of nitrogen of urea to total nitrogen of urine.

A method of preparing fat-free meat, O. FRANK (*Ztschr. Biol.*, 35 (1897), No. 4, pp. 549-554).—The author proposes the following method for removing the fat from meat: Cover the finely chopped meat with 96 per cent alcohol, soak for twenty-four hours, shaking often, and remove the alcohol with a pipette. Repeat the treatment three times with absolute alcohol and then with ether, dry the meat residue, pulverize, and extract twenty-four hours with ether in a Soxhlet apparatus. Unite all the alcohol and ether extracts, evaporate at gentle heat (preferably in a vacuum), and dry in a vacuum at 100°. Take up the residue with chemically pure ether, or better still, with petroleum ether (boiling point 60°), filter, evaporate, and weigh. If a clear solution is not obtained, evaporate and dissolve a second time in petroleum ether. This method of extracting fat gives about 10 per cent more than the ordinary method in terms of the total fat estimated.

The author compares his method with that in ordinary use. When 6.851 gm. of meat powder dried at 70° was extracted by the ordinary method ether extract equal to 2.57 per cent of the total substance was obtained. When 24.12 gm. of fresh meat

was extracted by the alcohol-ether method the quantity of ether extract obtained was equal to 2.89 per cent of the total substance.

In order to show that the residue from extraction with alcohol and ether was free from fat the author dissolved the residue from 20.52 gm. of fresh meat in 50 per cent sulphuric acid, extracted the solution with ether, and obtained only 0.0021 gm. of ether extract.

In the author's opinion, when muscle fat is heated in the presence of moisture at 100° in the ordinary method of drying meat for extraction, cleavage takes place.

In carrying on the investigations, it was observed that the ether extract from muscular tissue contained a high percentage of free acid. Since there is little fat in subcutaneous connective tissue, as also in the insoluble fat of the muscles, it seemed possible that the fatty acid was in some way connected with the muscle protoplasm and was dependent upon muscular exertion. Experiments were therefore made with a dog and the amount of fat in working muscles was compared with that in resting muscles. Contradictory results were obtained.

On account of its interest in connection with a discussion of the formation of fat from protein, the author repeated an experiment made some years ago by F. Hoffmann. Maggots of flies were grown upon meat which had been extracted for fourteen days in a Soxhlet apparatus. After seven days the maggots were analyzed and it was found that they contained more fat than maggots had been shown to contain at the beginning of the test. Since the gain in fat was not large it can not be said with certainty that it was not made at the expense of the small quantity of fat remaining in the meat after the fourteen days' extraction with ether.

Feeds and feeding, W. A. HENRY (*Madison, Wis.: The author, 1898, pp. IV + 677*).—This is a comprehensive manual edited for students and practical feeders. It is divided into three main sections, (1) plant growth and animal nutrition, (2) feeding stuffs, and (3) feeding farm animals. Under the first section the growth of the plant and its suitability for animal food and the digestion and assimilation of food by animals are discussed, as well as the laws of animal nutrition, the source of energy in the animal body, the influence of food on the composition of the body, and similar topics. Directions are given for calculating rations for different animals under different conditions. Under the second main division the different cereals, oil-bearing and leguminous seeds, the by-products made from them, forage plants, roots, and miscellaneous feeding stuffs are described and discussed; the manurial value of the different feeding stuffs is treated of at length, and soiling and ensiling are described. In the third main division feeding the different farm animals for growth or for the production of force is treated in detail as well as the feeding of dairy cows for the production of milk. Special attention is also given to the feeding of sheep for wool.

The author has made an extended study of the experiment station publications on the various subjects treated of, as well as the general foreign and American literature. The work of many investigators and the conclusions drawn are quoted with much detail. In many instances results are discussed in their bearing upon other investigations. In an appendix the average composition of the principal feeding stuffs is given, feeding standards are quoted, and a glossary of the more unusual terms is included. The value of the work is increased by the citation of references and an index.

Hay of Norwegian fodder plants, F. H. WERENSKIOLD (*Tidsskr. Norske Landbr., 4 (1897), No. 10, pp. 436-440*).—A continuation of the study of the composition of Norwegian fodder plants begun by the author in 1894 (*E. S. R., 6, p. 568; 9, p. 268*). The present report includes analyses of samples of hay from legumes (8 samples) and from grasses (15 samples).—F. W. WOLL.

The method to be followed in considering the subject of animal production, MÜLLER (*Jour. Landw., 46 (1898), No. 2, pp. 143-151*).—The author divides the sub-

ject into (1) breeding, (2) feeding and feed stuffs, (3) hygiene, (4) races, breeds, and strains of domestic animals, and (5) societies for the advancement of animal production. These main divisions are further subdivided.

Feeding of new oats (*Tidskr. Landtmän*, 18 (1897), No. 37, pp. 665, 666).—It is stated that from eight to ten weeks should pass after harvesting before oats are fed to horses.

Measurements and weights showing the development of horses and bulls, S. C. A. TUXEN (*Landmansblad*, 30 (1897), No. 42, pp. 578-582).

On the red Danish cattle, (*Landtmann*, 8 (1897), No. 40, pp. 561-564, ill.).

Potatoes as a food for swine, H. KNUDSEN (*Nord. Mejeri Tidn.*, 12 (1897), No. 41, pp. 486, 487).

Horse breeding in Austria-Hungary (*Jour. Bd. Agr.* [London], 98, No. 4, pp. 456-460).—This article, which gives statistics and other information concerning horse breeding in Austria-Hungary, is prepared from a report by M. de C. Findlay in the "Appendix to the Minutes of Evidence taken before the Royal Commission on Horse Breeding in Ireland [C.—8652]."

The hygiene of the horse, H. GOLDSCHMIDT (*Hestens Sundhedspleje*. Copenhagen: Det Nord. Forlag., 1897, pp. 104).

On poultry raising and egg trade in Denmark, A. OEKSNEVALD (*Tidsskr. Norske Landbr.*, 4 (1897), No. 10, pp. 461-471).

New treatise on practical aviculture, J. V. LASSERON (*Traité d'ariculture pratique*. Paris: Société d'Éditions Scientifiques, 1898, pp. 260, ill.).—This is Volume XI of *Encyclopédie des connaissances pratiques*. It is a popular handbook describing the different breeds of chickens and other poultry. The diseases of poultry are also discussed. There is a chapter on rabbits.

DAIRY FARMING—DAIRYING.

Investigations on the care and keeping of milch cows, BACKHAUS (*Ber. Landw. Inst. Univ. Königsberg*, 2 (1897), pp. 34-89).—These investigations were made upon a part or the whole of the herd at the Agricultural Institute. They include studies of the individual variation in milk yield and the utilization of food by different cows, feeding and milking twice or three times a day, watering, effect of exercise, light in the stable, etc.

The individual variation in milk secretion.—The record is summarized for eight East Prussian Dutch cows, together with the creamability of the milk of each cow, number of fat globules, live weight, etc. The yield of solids-not-fat varied all the way from 2.33 to 3.02 times the total yield of fat with different cows, supporting, the author believes, his theory that some cows are primarily butter cows and others cheese cows. No relation was found between the live weight and the milk production. The milk of different cows varied materially in the size of the fat globules, and this affected the centrifugal creaming of the milk, the effect of the larger globules being noticeable, not especially in the fat content of the skim milk, but in increasing the fat content of the cream.

Utilization of food by milch cows.—From the record of the eight cows the food units consumed are calculated from the digestible food eaten with the use of Kühn's proportion of protein 6, fat 2.5, and nitrogen-free extract 1; and the milk units produced are calculated on the basis of

1 kg. of fat or 5 kg. of solids-not-fat to 1 milk unit. The results of these calculations are given in the following table:

Relation between food consumed and milk produced by different cows.

Cow number.	Total milk units produced.	Total food units consumed.	Food units consumed for production of 1 milk unit.
1.....	141.80	3,410.70	25.49
2.....	139.08	3,327.34	23.92
3.....	113.70	3,270.29	28.76
4.....	150.48	3,434.69	22.82
5.....	141.36	3,410.70	24.13
6.....	120.58	3,095.56	25.67
7.....	134.18	3,425.24	25.66
8.....	137.12	3,430.31	25.02
Total.....	1,078.30	26,804.83	24.86

To the above is added the values of the milk units and food units, and the cows are arranged according to production and profit. The author concludes that the merits of a cow can best be judged of by testing the amounts of food consumed and the production of milk, etc., six months after calving. With a view to finding a practicable means by which the profitable utilization of food by a cow (*futterdankbarkeit*) could be determined, studies were made in which at four different stages of lactation the grain of the eight cows was increased and the effect observed on the production. The periods were each seven days long, the last four days being considered. There was a wide difference among the cows with respect to their response to the increased grain. Some gave no increase, while others in every case gave a noticeable increase in production.¹

The author considers that the results warrant the making of such tests in practice in studying the value of cows.

Feeding twice and three times a day.—The results are given of three experiments on this subject with different lots of cows. The conclusion is that for milk production alone it is sufficient to feed twice daily, as feeding three times gave no increase in the yield of milk. Physiologically feeding only twice a day is believed to be preferable, as the cows are more quiet under this system. Where the production of beef is considered, feeding three times a day is considered advisable, as there was a greater increase in live weight under that system.

The watering of cows.—The author reports an experiment previously noticed (E. S. R., 4, p. 773). In addition, an experiment is given with eight cows, lasting from September 5 to October 9, 1897. Every other week the cows were supplied with water in the stalls by means of automatic troughs, and on alternate weeks they were watered with pails. The average milk yield was 14.79 kg. when water was supplied automatic-

¹ It would appear that all of the animals were fed the same amount of basal ration and of grain without regard to live weight.

ally, and 14.18 kg. when the cows were watered with a pail. There was practically no difference in the amount of fat and of solids-not-fat produced under the two conditions. The cows drank nearly 2 liters more of water per day when the water was kept before them. Summing up the two experiments, the author believes the results show that automatic troughs materially increase the milk production and are to be recommended.

Effect of exercise on milk secretion.—An experiment on this subject was made with eight cows from October 17 to November 20, the cows being turned out in a yard and allowed to exercise at will for an hour each day on alternate weeks, but during the rest of the time kept in the stable all day. The average yield of milk was 12.31 kg. for the weeks the cows were exercised and 11.88 for the time they were given no exercise. There was practically no difference in the yield of fat and solids-not-fat. An increase in milk yield was shown by all of the cows when they were given exercise.

Milking twice, three times, and four times a day.—An experiment is reported with eight cows in milking twice, three times, and four times daily, the interval between milkings being divided equally. The periods were seven days long and only the last four days of each period were considered. Frequent milking was found to increase the yield of milk, and this was true for fresh cows as well as those well advanced in milking. The author is convinced that under intensive conditions, where milk commands a high price, the increased yield will warrant milking three times a day, dividing the time between milkings as equally as possible. Under other conditions milking twice a day is considered sufficient except in the case of cows giving a large quantity of milk, which should be given two additional milkings. Concerning the composition of the milk at different milkings, on the average of nine weeks of milking twice daily, the morning's milk contained 3.42 per cent of fat and the night's milk 3.47 per cent; the average of three weeks of milking four times a day gave 3.60 per cent of fat for the forenoon's milk and 3.47 for the afternoon's milk. Where the time between milkings was irregular it was found that a milk richer in fat was produced on the shorter interval.

Changes of milk as a result of being in heat.—The results of two series of observations each on five cows are given. The results indicate that the changes in the milk due to the cow being in heat are relatively unimportant and may be entirely avoided when the milk is to be used for ordinary purposes. For special purposes, as the production of milk for infants, it is advisable to reject the milk at this time.

Effect of light.—The results are given of three experiments on the effect of light on cows. In each experiment the windows were darkened during the alternate periods and the stables kept as dark as practicable. In general, the results of all the experiments showed that excluding the light had little effect on the milk production, but the

effect on the live weight appeared to be unfavorable. The advantages of well-lighted stables are considered apparent.

On the influence of the food on the fat content of the milk, F. FRIIS (*Mælkeritid.*, 1897, Oct.; *Norsk Landmansblad*, 16 (1897), No. 45, pp. 498-501; *Biet.*, 18, (1897), pp. 238-247).—The author reviews the cooperative cow-feeding experiments conducted at the State experiment station at Copenhagen since 1888, with special reference to the effect of food on the fat content of the milk (E. S. R., 9, p. 490, and previous volumes). The following summary of 76 series of experiments is reproduced from the paper:

Summary of Danish feeding experiments with cows on the effect of food on quality of milk.

Year.	Number of series included.	Lot.	Basal ration.	Additional rations in experimental period.	Fat in milk.		
					Preparatory period.	Experimental period.	Post-experimental period.
					<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>

		C		3½ lbs. molasses feed.....	3.26	3.15	3.27

¹ Amounts are stated in Danish pounds, 1.1 lbs. avoirdupois.

In the opinion of the writer the experiments prove that "the feed under practical conditions, as found in this country, exerts an entirely insignificant (*forsvindende*) influence on the fat content of the milk." It is noted that although the differences in the rations fed to the different lots were considerable the rations may all be regarded as normal for milch cows, such as met with in the feeding practice on Danish dairy farms. The question whether abnormal feed mixtures can appreciably change the fat content of milk was not included in the investigations of the station. Only the effect of the food on the percentage of fat in the milk is considered in this paper. The author notes that the experi-

ments showed that different feeding stuffs and food mixtures in a very large measure influence the quantity of milk yielded, as well as the health and general condition of the cows.—F. W. WOLL.

Obtaining milk under aseptic conditions, BACKHAUS and W. CRONHEIM (*Ber. Landw. Inst. Univ. Königsberg, 2 (1897), pp. 12-32*).—This article treats of the method of obtaining milk as free from germs as possible. The author believes that the more recent investigations show the impossibility of obtaining milk from the udder of the cow, either by milking tubes or by washing the udder, etc., which is entirely free from germs. The results are given of the determination of the germ content of milk from numerous creameries in Göttingen and Königsberg during several months of the year. These showed very wide variations—from about 2,000 to over 20,000,000 germs (per cubic centimeter).

The milk of eight cows of the university herd, which was milked with care into a sterile pail, rejecting the first five spurts of milk, showed a germ content ranging in six trials from 1,800 to 14,750, the average for the whole being 6,660. In many trials using milking tubes or milking into sterile vessels, the lowest germ content found was 1,300. It was frequently found that at a low temperature the germ content of milk changed very little, although in some cases there was a decrease.

The increase which may take place in handling milk by pouring it from one vessel to another and in cooling, is shown by three experiments, summarized as follows:

Germ content of milk before and after handling.

	Experiment of—		
	July 8.	July 14.	November 17.
Directly after milking.....	14,400	19,600	10,800
After pouring into another vessel.....	19,400	28,600	6,600
After passing through the milk cooler.....	21,600	38,000	39,600
After catching in another vessel under the cooler.....	21,400	78,600	17,600
After filling in bottles and keeping for four or five hours in the cold...	35,000	162,000	23,200

Several experiments are given showing the infection from the cow's body, from which it is concluded that the cows should be carded and brushed twice daily and the udder and adjoining parts washed once.

Numerous experiments are also reported on the effect of the surroundings of the cow, bedding, excrement, feed, and manner of milking on the germ content. It is concluded that for obtaining aseptic milk the conditions are best in milking in the open air, although the proper ventilation and general cleanliness of the stall are important matters. Peat is regarded as a very favorable bedding, and if straw is to be used it should be fresh and clean and free from any mold, dampness, etc. The lowest germ content of the milk was observed when peat was used for bedding. Experiments showed that infection with old manure was

especially to be guarded against, as this contains more particularly the peptonizing bacteria. This relates to manure which is allowed to accumulate in the stall or dry upon the cows. Experiments by the author and those cited from other investigators indicate that it is important in obtaining milk with low germ content to avoid all feeding stuffs in a state of fermentation or in a spoiled condition. The germ content may also be reduced by keeping the milk from the first part of the milking—about one fourth—separate from the rest and using it for a different purpose. The use of a milk pail having a cover with only a small hole in the top is recommended instead of an open pail.

The effect of dairy utensils of different kinds—wood, tin, enamel, etc.—is considered, and also the cleaning of dairy utensils. Wooden utensils should be avoided. Sodium hydrate is recommended for cleaning dairy utensils, followed by washing and scalding with water and sterilizing with steam under pressure or in a sterilizing oven.

In conclusion a diagram is given showing the effect of various methods of treatment, as noted above, in reducing the germ content of the milk. It is stated that by avoiding some of the precautions milk may contain 2,000 times as many bacteria as that obtained when all precautions are observed. This shows the importance of employing “aseptic” methods in obtaining and handling milk for domestic purposes.

Some new experiments in churning (*Milk. Ztg.*, 11 (1897), No. 52, pp. 817, 818).—A short account is given of some experiments by Fahrenbach at the Agricultural Institute at Leipsic. The effect of the size of the fat globules on the rapidity and the completeness of churning was studied in 8 series of experiments with sweet cream and 6 with ripened cream. The milk of two cows, distinguished by the difference in the size of the fat globules, was mixed, and from the mixture cream with large and with small globules was prepared by a method not noted in the abstract. The two kinds of cream were alike in fat content and in other respects except the size of the globules. The average results with the sweet and ripened cream were as follows:

Churning properties of cream with large and small fat globules.

	Number of globules in 0.000001 cc. of fat.	Time required for churning.	Degree of churnability.
		<i>Minutes.</i>	
Sweet cream:			
Cream with large fat globules.....	30.04	46	95.12
Cream with small fat globules.....	104.61	54	91.61
Ripened cream:			
Cream with large fat globules.....	28.80	42	97.13
Cream with small fat globules.....	87.30	58	95.00

The cream with large fat globules churned quicker and more completely than that with small globules, and the difference in respect to thoroughness was greater in case of the sweet cream. On an average

the churnability of the ripened cream was nearly 3 per cent greater than that of the sweet cream. Experiments were also made with cream of different fat content and from different kinds of cows. The results of these experiments, which are not detailed in the abstract, showed that under some circumstances the effect of the size of the fat globules on churning may be obliterated by other conditions. A fat content of the cream too high or too low to be advantageous diminishes the churnability in a greater degree than large fat globules increase it. The viscosity of the cream also had a very marked effect on the churning.

An account is also given of von Stockhausen's investigations (E. S. R., 9, p. 1087).

Effect of period of lactation on milk and quality of butter, G. L. MCKAY and J. W. WILSON (*Iowa Sta. Bul. 36, pp. 865-867*).—In continuation of previous work (E. S. R., 9, p. 91) a test was made with two lots of 4 and 7 cows, respectively, to study the effect of the period of lactation upon milk yield and the quality of butter. The first lot averaged sixty-two days since calving, and the second lot one hundred and ninety-five days. The two lots were fed, under like conditions, the same rations of sheaf oats, clover hay, corn, barley meal, and sugar beets. The total milk yield in fifteen days from lot 1 was 972 pounds, and from lot 2, 886 pounds. The milk from each cow was kept separate, the cream was removed by a separator, and the butter was made and handled by the same methods. The butter was judged by an expert, and no difference was observed as due to a difference in the period of lactation.

The authors believe that the trouble experienced with cream from cows in an advanced stage of lactation is due to the fact that the cows are not fed a sufficiently succulent ration. As the period of lactation advances the fat globules in the milk become smaller and the cream more viscous. Succulent food, it is stated, will cause a more abundant secretion of milk furnishing less viscous cream. The authors also advise the addition of sour milk to start the ripening of the cream. This insures a rapid development of lactic-acid fermentation, and retards the growth of undesirable microorganisms. When the cream is properly ripened they believe no difficulty will be experienced in churning it.

Investigations on the utilization of casein, BACKHAUS (*Ber. Landw. Inst. Univ. Königsberg, 2 (1897), pp. 1-11*).—The author points out that the fat of milk sells for about twice as much as the casein, although the relative nutritive value of fat to protein is given by König as 3:5 for human food and by Kühn as 2.5:6 for animal nutrition. The author believes that in the interest of dairying some means should be found for utilizing the casein more profitably. The uses to which casein has already been put in the industries and as a food for man and animals are noted.

The author made numerous investigations to find a practicable method by which the casein might be precipitated from milk and prepared commercially for food. The plan which he finally worked out consists in curdling the casein with rennet and converting the casein into a soluble form. It was found that the latter could be accomplished by adding certain salts to the casein, as trisodium citrate. Experiments showed 2.5 gm. of the citrate per liter of milk to be the best amount. The preparation was partially freed from water by pressing and then dried at a temperature of from 50 to 60 °C., preferably in a vacuum or a well ventilated oven. The final product is a white powder, nearly free from taste or odor, which dissolves in water, giving a cloudy solution. In order to prevent the solution from curdling on heating, the sodium citrate used in preparation may be made slightly alkaline, or about 10 per cent of carbonate of soda may be added to the salt. It was found in further experiments that the casein could be rendered soluble by rubbing the mixed precipitated casein with a mixture of 1.5 gm. of sodium citrate and 1 gm. of trisodium phosphate for each liter of milk originally taken.

The author believes the method is so simple that it may be employed at creameries without difficulty. An experiment on a large scale is to be undertaken, together with experiments on the use of the preparation of casein for cooking and for food.

Report of the milk-control station in Christiania, Norway, 1897 (*Norsk Landmansblad*, 17 (1898), No. 3, p. 31).—During 1897, 32,259 samples of milk, cream, skim milk, etc., were analyzed for fat content (by the De Laval butyrometer), 27,419 of these being samples of new milk. The average percentage of fat in the new milk was 3.467, against 3.41 per cent in 1895 and 3.461 per cent in 1896. The monthly averages in 1897, each of which include analyses of about 2,000 samples, ranged between 3.322 per cent (in April) and 3.745 per cent (in October).—F. W. WOLL.

Indigo carmin as a means of testing fresh milk, L. VAUDIN (*Rev. Internat. Falsif.*, 11 (1898), No. 1, pp. 24, 25; *abs. in Ztschr. Angew. Chem.*, 1898, No. 14, p. 324).

On the determination of fat in cream, butter, and cheese, N. GERBER and M. M. CRAANDIJK (*Milch Ztg.*, 27 (1898), No. 3, p. 35).—Preliminary report of a modification of Gerber's method, by which reliable determinations of the fat in cream, butter, and cheese can be made.—F. W. WOLL.

Further remarks on the determination of the fat content of cream, N. GERBER and M. M. CRAANDIJK (*Milch Ztg.*, 27 (1898), No. 5, pp. 65, 66).—Quotes largely from Farrington and Woll's book on "Testing Milk and Its Products," as to the sources of error in cream testing.—F. W. WOLL.

On the accuracy of centrifugal methods of fat determination for the examination of cream, H. SCHROTT (*Milch Ztg.*, 26 (1897), No. 52, p. 830).—Dilution of cream with water or with skim milk of known fat content previous to the

analysis gives unsatisfactory results. The author recommends the construction of special test bottles for cream.—F. W. WOLL.

Determination of fat in cream by Gerber's acid-butyrometric method, M. SCHMOEGER (*Milch Ztg.*, 27 (1898), No. 3, pp. 33-35).—The author calls attention to the possible error in the Gerber method arising from impure amyl alcohol, or from adding the acid and the amyl alcohol in other proportions than those given by the inventor. He shows that the method does not give reliable results with cream when tests are made according to Gerber's directions. By a modification proposed, viz. dilution of 1 part of cream with 2 parts of water and adding acid and amyl alcohol in the same proportions as in case of tests of whole milk, fairly satisfactory results were obtained. The difference between the results obtained by gravimetric analysis and by the modified method was within 0.5 per cent.—F. W. WOLL.

VETERINARY SCIENCE AND PRACTICE.

On the results of the rinderpest investigations at Koch's experiment station in Kimberly (*Deut. Med. Wchnschr.*, 23 (1897), No. 50-51; *abs. in Centbl. Bakt. u. Par.*, 1. Abt., 23 (1898), No. 8, pp. 337-341).—The injection of gall was found to be ineffective. The immunizing power of the gall is attributed to chemical properties, which, contrary to Koch and Edington's experience, are weakened by the addition of glycerin. The use of gall is safe, since it causes no trouble even when mixed with the feed of the animals or dropped into their nostrils, nor are animals treated with it dangerous to other animals. Rinderpest generally spreads by natural infection. Cases of sickness following gall injection are attributed to previous infection.

Of 1,056 animals treated on 21 farms, 150 became diseased and 110 died; but of 587 injected animals none were lost. Another case cited shows a loss of 20 per cent of treated as compared with a loss of 82 per cent of untreated animals. Where herds were already infected deaths were most numerous. In one extreme case 114 animals out of 147 were lost. That no deaths can be attributed to the gall employed is shown by the fact that where the same gall was used animals were lost in some and not in other herds.

The immunity obtained by the injection of gall appears only some six days after the operation and is then of short duration. A serum obtained at the station has given much better results. With doses of 20 cc. or less, an animal in the first stages of rinderpest can be cured, while doses of 50 to 100 cc. has produced the same desirable effect in animals in all but the very last stages. Animals were treated with it which at intervals had received injections of virulent blood amounting to 50, 100, 200, 500, 2,000, 3,000, and 4,000 cc. A fever reaction of several days' duration followed treatment. A dose of 30 cc. of blood (equal to 20 cc. of serum) from such animals was found to protect others for two to three weeks. Of 24 noticeably diseased animals all were saved by such small doses, while 2 animals already diseased that had received 500 cc. of virulent blood were saved by a dose of 200 cc. of serum.

Comparing the results of the two methods and nontreatment, the case of a diseased herd where 85 animals had died is cited. The remainder (482) were inoculated with gall. Some four months later only 9 per cent had died. At this time, of 16 animals found to be diseased 1 was sacrificed, to make sure that rinderpest was being dealt with, and the remainder of the herd, including the 15 diseased, were treated with serum at the rate of 30 cc. per animal. All were saved. At another place, where 48 animals had been lost, only 16 of the remainder (76) were sound. Treatment with serum saved all but 7 already in a hopeless condition. At another farm 101 of 285 animals had died. Of the remainder 25 per cent were saved by serum injected at the same rate as in the former case. One herd of 376 had lost 4, and inoculations with serum at the rate of 20 cc. saved all but 16. In another herd of 472 animals, 166 had been lost. After treatment with serum only 46 died. According to Russian experience, immunity following natural infection lasts for about five years. At the Kimberly station immunity was obtained with gall for four months with glycerin and gall mixed in the proportion of 3 to 4 for ten to twenty days. This period of immunity was raised by following the treatment of gall by the injection of $\frac{1}{2}$ to 1 cc. of virulent blood on one side of the animal and an injection of 10 to 20 or 30 cc. of serum on the other side. The places of injection, it is stated, should not be less than half a meter apart. Of 350 animals treated in this way only 5 per cent were lost.

Compared with other serums, diphtheria serum, for example, the

curative power of the Kimberly serum seems high. Doses of from 5 to 10 cc. of diphtheria serum are said to cure, but a dose of 10 cc. of the Kimberly serum has cured animals of 360 kg. weight when injected two days after infection. Calculated in weight, 1 gm. of the Kimberly serum is equal to 36,200 kg. of animal; or, considering only the chemical substances, the author gives the curative ratio analogously to that of the diphtheria serum of Brieger-Boer as 1 to 360,000,000.

How different the Kimberly serum is from the normal may be seen from the fact that 1,000 cc. of the latter will not protect an animal when injected twenty-four hours after the injection of $\frac{1}{2}$ cc. of virulent blood. Whether the serum is antitoxic or microbicidal remains to be decided, though the authors suppose it may be microbicidal.

The sheep fluke, N. A. COBB (*Dept. Agr. New South Wales, Misc. Pub.* 167, pp. 32, figs. 30, pl. 1).—In this pamphlet there is given a popular account of the sheep fluke as it exists under Australian conditions, together with suggestions as to the methods of dealing with it.

In a study of the life history of the sheep fluke the cercaria of the latter were found, after long search, in the snail (*Bulinus brazieri*), a species entirely different from that serving as the intermediate host of the sheep fluke in Europe.

The author's remedial recommendations are all of a preventive sort. The burning of pasture lands it is thought may do some good, but the best methods are those of draining swampy lands, fencing them off so as to keep sheep away from them, or the formation of ditches or reservoirs for the collection of drinking water in such a way that it can not be contaminated by dung, and so become infected with the free swimming larvæ of the fluke. The rotation of stock upon pasture lands is also among the remedial measures recommended; that suggested as the best is sheep, horses, bullocks, horses, sheep.

A few notes are given on the Australian snail-eating birds, viz, the common mud lark, magpie lark or peewee (*Grallina picata*), pied grallina (*Grallina australis*), and the white fronted heron (*Ardea nova-hollandiae*).

Contribution to the natural history of *Trichina spiralis*, J. Y. GRAHAM (*Arch. Mikros. Anat.*, 50 (1897), No. 2, pp. 214-275, pls. 3; *abs. in Zool. Centbl.*, 5 (1897), No. 2, pp. 47, 48).—The author substantiates what has been observed several times heretofore, that the female deposits the brood not in the lumen of the intestine, but under the epithelium of the intestinal mucous membrane. The males are also found in the latter place. The young worms reach the lymph vessels and lymph glands, and then the *ductus thoracicus* of the blood vessels. When they reach the striated muscles they leave the blood capillaries and enter the muscle tissue. The penetration of the sarcolemma and the wandering about inside the muscle fibers, observed heretofore, is confirmed. If the trichina reach the cardiac muscle they perish. Their fate is the same also if they get into the pericardium or peritoneum. The author does not believe in the poisonous action of the worms. Two small

glands on the border of the oesophagus and the gut, which he calls chylestomachs, belong to the gut.

Tuberculosis in cattle and tuberculin, NOCARD (*Montargis, 1896; abs. in Arch. Wiss. u. Prakt. Thierheilkunde, Berlin, 22 (1897), No. 2-3, and in Centbl. Bakt. u. Par., 1. Abt., 22 (1897), No. 18-19, pp. 563-567*).—It is noted that in 1893, in the slaughterhouses of Prussia, out of 695,852 grown cattle, 62,312, or 8.9 per cent, were found tuberculous. At Berlin the percentage was 15.1 (in 1892, 12 per cent); at Magdeburg as high as 17.5 per cent. In the same year in Saxony of 69,164 animals, 12,630, or 18.26 per cent, were found diseased. At Amsterdam and Moscow the percentage was 5.5; in Mariland, 10 per cent; at Copenhagen, 17.7 per cent. These data are compared with French statistics taken in 1889. At Toulouse of 13,057 animals slaughtered, 1,254, or about 10 per cent, were tuberculous. In this year the law relative to the confiscation of animals affected with generalized tuberculosis went into effect and the number of tuberculous animals sank so that, of 12,694 animals, only 340 were found to be affected. For the same reason the number of such animals found at Bucharest sank to less than 3 per thousand. But when an indemnity was granted the owner of condemned animals the number suddenly increased to 30 per thousand.

In Great Britain, according to the author, the slaughterhouses are still in a rudimentary condition. The percentages mentioned are 12.5 in 1891 and 22.3 in 1892. The latter large percentage is attributed to slaughter of milk cows of London and Edinburgh.

In France certain regions, as Auvergne, Limousin, and the greater part of Normandy, are entirely free from the disease. For all France the percentage of tuberculous animals is placed at less than 1 per cent. But the statistics are not completely trustworthy and we must conclude that the disease is generally distributed.

The following increases are noted: Saxony, 1890-1893, 16.4 to 18.26 per cent; Berlin, 1891-92, 12 to 15.1 per cent; Leipsic, 1888-1893, 11.1 to 28.1 per cent; Schwerin, 1886-1894, 10.7 to 35 per cent.

The introduction of shorthorns in 1850 into Denmark is charged with raising the percentage there. By the use of tuberculin the percentage was raised from 17 per cent in 1893 to almost 40 per cent in 1894-95.

Other statistical facts of interest are that the author considers 4 to 5 per cent to represent the number of cattle with tuberculous udders. Also, that in a region where some 15 to 25 per cent of the cows were affected only 1 per thousand of tuberculous calves was found, and from other tuberculin studies where 40 to 80 per cent of the cattle were affected calves from 4 to 15 months old were not found diseased. Of 44 calves 6 to 18 months old; 33 were sound, and of the dams of these 26 were tuberculous. The sick were isolated from the sound, and repeated injections in 1893, 1894, and 1895 produced no reaction.

The author's conclusions are of considerable interest. Tuberculin injections can not produce the disease in sound animals: it is useless

only in the advanced stages of the disease, when the latter is readily recognized by other means. Other diseases, such as actinomycosis, verminous bronchitis, and echinococcus, do not cause a reaction unless accompanied with tuberculosis. But there is here a territory still open for investigation. Only 3 cases in 3,500 were found in which tuberculin injections appeared to hasten the disease; it has no influence on the bacillus in the milk. Only 5 per cent of the cases tested by the author refused to react to the second injection.

Relative to the assertion that reactions occur in sound animals, the author states that evidence of the disease is sometimes very difficult to find in post-mortem examinations, and cites the fact that at the congress of veterinarians in Bern two apparently sound animals reacted. One was killed and after a long search no traces of the disease found. This was thought to be evidence against the surety of the tuberculin. While others were occupied with the second animal the author made a further examination of the first, and was rewarded by finding a small lesion the size of a hazelnut near the bifurcation of the bronchi.

Pernicious and epizootic anemia of sheep, C. JULIEN (*Ann. Agron.*, 23 (1897), No. 12, pp. 575-588).—The disease—attributed to *Strongylus contortus*—is generally distributed over France. There is noted a varietal as well as an individual resistance to it. Evidence of the disease appears in flocks of sheep in July or August or about the time for lamb weaning. The first infection seems attributable to weeds of low meadows that become contaminated by the droppings of the sheep and to water contaminated in the same way. The remedial measures noted are the raising of resistant varieties of sheep and the proscription of all sources of infection. Manures, litter, etc., may be treated with anthelmintic and the sheep given a mixture of 6 to 8 cc. benzoin (5 to 6 cc. for lambs), and 15 to 20 centigrams of arsenious acid per head for some 8 days.

Echinococcus multilocularis in sheep, MOEBIUS (*Ztschr. Fleisch u. Milchhyg.*, 7, No. 6; *abs. in Centbl. Bakt. u. Par., 1. Abt.*, 22 (1897), No. 20-21, p. 619).—One specimen was found in the lungs and five in the liver of a sheep. An Echinococcus was likewise found in a bronchial gland.

Injection experiments on calves with human tubercle bacillus, FROTHINGHAM (*Ztschr. Tiermed.*, 1 (1897), p. 330; *abs. in Centbl. Bakt. u. Par., 1. Abt.*, 22 (1897), No. 20-21, pp. 633, 634).—It was endeavored to learn whether calves are less susceptible to human than to bovine tuberculosis. Of 4 calves injected with pure cultures of human tuberculosis, only 3 showed after death evidence of tuberculosis and in no case were the changes of great extent or a general infection such as was found in control guinea pigs. One calf escaped tuberculosis entirely.

Differential diagnosis of wandering trichina, GEORGES (*Ztschr. Fleisch u. Milchhyg.*, 7, No. 8; *abs. in Centbl. Bakt. u. Par., 1. Abt.*, 22 (1897), No. 20-21, p. 620).—In a preparation of the striated muscle of a hog there were found between the fibers with only a magnification of 30 diameters round worms of the size and form of embryos of *Strongylus*. The worms were considered to be embryos of *Strongylus paradoxus*. They were distinguished from trichina by the bluntness of the oral end.

Strongylus paradoxus in the liver of the hog, W. SELLMAN (*Ztschr. Fleisch u. Milchhyg.*, 7, No. 10, p. 196; *abs. in Centbl. Bakt. u. Par., 1. Abt.*, 22 (1897), No. 20-21, p. 619).—Numerous specimens were found in the gall ducts.

Texas fever, J. W. CONNAWAY (*Missouri Sta. Rpt. 1897*, pp. 81-119, figs. 11).—A reprint of Bulletin 37 of the station (E. S. R., 9, p. 188).

The cause and treatment of abortion in cows, J. SCHMIDT (*Tidsskr. Landökon.*, 16 (1897), No. 5-6, pp. 490-504).

The disposal of the carcasses of dead animals, A. MOREL (*Des clos, d'équarissage. Paris, 1897; rev. in Jour. Hyg., 23 (1898), No. 1123, p. 156*).—The need of inspection and precautionary measures is insisted upon, in the disposal of the carcasses of animals, to prevent the spread of diseases through the use of the flesh of diseased animals without properly sterilizing, and of the fat in manufacturing, etc.

TECHNOLOGY.

Analysis of molasses from beets and sugar cane—Determination of saccharose, raffinose, and invert sugar, S. DRACZKOWSKI (*2. Congrès Internat. Chim. Appl., 1896, I, pp. 31-39*).

Analysis of molasses, C. LIESSE (*2. Congrès Internat. Chim. Appl., 1896, II, pp. 466-473*).

Wine fermentation experiments in France, J. C. COVERT (*U. S. Consular Rpts., 1898, No. 210, pp. 411-414*).—Popular notes are given on the use of pure yeast cultures in the fermentation of wine must. Opinions are said to differ respecting the value of such ferments, but the majority of the evidence seems to go to prove the value of such methods in wine making.

The preparation of tannin extracts and the determination of their commercial value, P. JEAN (*2. Congrès Internat. Chim. Appl., 1896, III, pp. 91-93*).

STATISTICS—MISCELLANEOUS.

Tenth Annual Report of Louisiana Stations, 1897 (*Louisiana Stas. Rpt. 1897, pp. 12*).—A report on the operations of the Sugar Experiment Station at Audobon Park, New Orleans, the State Station at Baton Rouge, and the North Louisiana Station at Calhoun, with a list of the bulletins published during the year and the organization of each station. A financial statement is given for the fiscal year ending July 1, 1897, together with a subject list of the first and second series of station publications and of special bulletins issued. At the Sugar Experiment Station at Audobon Park sugar-cane seedling No. 71 grown for four years yielded in 1897 "over 40 tons per acre and with a mill extraction of 78 per cent; its juices had a density of 18° Brix, and polarized nearly 17 per cent sucrose." Alfalfa and velvet bean (*Dolichos multiflorus*) are reported as having given excellent yields at the same station.

Annual Report of Missouri Station for 1897 (*Missouri Sta. Rpt. 1897, pp. XI+209*).—Contains the financial report of the station for the fiscal year ending June 30, 1897; a report by the director reviewing in considerable detail the work of the station during the year, with notes on the station staff and a list of the publications of the station issued in 1897; and an appendix made up of reprints of bulletins 34-39 of the station and an index to the same.

Sixteenth Annual Report of Ohio Station, 1897 (*Ohio Sta. Bul. 84, pp. LXVII+402-408, fig. 1, dgm. 1*).—This contains the report of the director on the work of the station for the six months ending June 30, 1897; subject list of bulletins 75 to 84 of the station; acknowledgments; treasurer's report for the fiscal year ending June 30, 1897; text of the addresses delivered at the dedication of the station administration building June 3, 1897; and a general index covering the publications included in the tenth volume of the station work.

Spain's foreign trade, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 11, pp. 47*).—This details and analyzes the data bearing on Spain's foreign trade for the ten years ending with 1895, dealing with the extent of the land and sea commerce and the nature of the same; sources and value of imports, and destination and value of exports; the extent of imports and exports carried in national

and in foreign ships; the value of the trade with each of the principal countries of the world; data on the Spanish merchant marine, and on the vessels entering and clearing from the several customs districts of Spain, and tonnage of the same; and notes and data relative to the duties levied upon agricultural products imported from the different countries of the world.

Our trade with Spain, 1888-1897, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 12, pp. 47*).—A review and analysis of the commerce between Spain and the United States during the years 1888 to 1897, compiled largely from the United States Customs Reports, with tables showing in detail the quantities and value of the principal items of merchandise exported to and imported from that country during each of the ten years under consideration. The United States trade with Spain has decreased since 1883, when the combined imports and exports amounted to \$24,725,632, to 1897, when the total trade amounted to but \$14,544,718.

Final report on the crops of 1897, J. HYDE (*U. S. Dept. Agr., Division of Statistics Rpt. 155, n. ser., pp. 30*).—"A report on the area, production, and value of the principal agricultural products for 1897, together with the farm prices of such products on December 1 last and a meteorological record of the growing season."

The following table summarizes this data for the whole country:

Area, production, and value of the principal crops of the United States, in 1897.

Crop.	Acreage.	Yield per acre.	Production.	Price per bushel. ¹	Value.
	<i>Acres.</i>	<i>Bushels.</i>	<i>Bushels.</i>	<i>Cents.</i>	
Corn.....	80,095,051	23.8	1,902,967,933	26.3	\$501,072,952
Wheat.....	39,465,066	13.4	530,149,168	80.8	428,547,121
Hay.....	42,426,770	² 1.43	³ 69,664,876	⁴ \$6.62	401,390,728

¹ Average price December 1, 1897.

² Tons.

³ Per ton.

⁴ Bales.

⁵ Per pound.

Of the cotton crop, 104,368 bales were sea-island cotton, valued at 14.36 cents per pound.

Natural resources of Asia Minor; its chief animals, plants, and minerals, K. KANNENBERG (*Kleinasien Naturschätze, seine Tiere, Kulturpflanzen und Mineralschätze. Berlin, Gebrüder Borntraeger, 1897, pp. 278, pls. 31*).—This is written from an agricultural and an historical standpoint and considers both wild and domestic animals and plants. The peculiarities of the various domestic animals and something of their commercial importance and uses are brought out. Many of the wild animals, insects, etc., are only briefly noted. In some cases something of the folk-lore concerning them is given.

Possibilities of agriculture in the Yukon district, W. SAUNDERS (*Central Expt. Farm, Ottawa, Canada. Experimental Farm Notes, Feb. 1898, pp. 7*).—The author has compiled information relative to the climatic and meteorological conditions of the upper Yukon region and gives notes on the possibility of growing vegetables in the vicinity of Dawson. Notes are also given on the most northern points in Canadian territory where cereals have ripened.

Experiment station notes on miscellaneous subjects, J. H. WORST (*North-Dakota Sta. Bul. 31, pp. 247-263*).—A popular bulletin "intended to be instructive on a number of subjects of every-day interest." The following topics are treated: Maintaining soil fertility, treatment of diseases of field crops, seed grain and methods of cultivation, trees and shrubbery for ornamental purposes, cultivation of small fruits, and organization of cooperative dairy associations.

The plow, cow, and steer (*Kansas State Bd. Agr. Quart. Rpt., 1898, Mar. 31, pp. 200*).—This popular, compiled report is "devoted to soil and crop culture as found

most suitable in Kansas, together with information as to better utilizing the cow and her products; the more profitable production of beef, wool, mutton, and poultry, and a higher order of home-making." The report also contains papers, addresses, and discussions at the twenty-seventh annual meeting of the board, January 12-14.

The potato and hay crops of 1897 (*Jour. Ed. Agr.* [London], 4 (1898), No. 4, pp. 433-435).—Statistics on these crops in Great Britain.

The rice crop of India, 1897, R. F. PATTERSON (*U. S. Consular Rpts.*, 1898, No. 210, p. 466).—Statistical notes.

Sugar in British Guiana, A. J. PATTERSON (*U. S. Consular Rpts.*, 1898, No. 210, p. 468).—A concise report on the sugar industry of British Guiana. It shows that there has been a continual decrease in the acreage of cane since 1892.

Wheat crop of India, 1897-98, R. F. PATTERSON (*U. S. Consular Rpts.*, 1898, No. 210, pp. 373, 375).—Statistics concerning the production and exportation of Indian wheat.

List of officials and associations connected with the dairy interests in the United States and Canada for 1898 (*U. S. Dept. Agr., Bureau of Animal Industry Circ.* 23, pp. 8).

Index to Iowa Station Bulletins 25 to 36 (*Iowa Sta. Bul.* 36, pp. 879-889).

Danish Agricultural Calendar, 1898, P. HOLT (*Lommebog for Landmænd.* Copenhagen, 1897, pp. 396).

Annual Report of the Royal Danish Agricultural Society, 1896-97 (Copenhagen, 1897, pp. 166).

Iceland's progress during the past twenty years, P. FELLBERG (*Tidsskr. Landökon.*, 16 (1897), No. 7-8, pp. 589-620).

The influence of width of tire on draft of wagons, H. J. WATERS (*Missouri Sta. Rpt.*, 1897, pp. 165-166, figs. 14).—A reprint of Bulletin 39 of the station (*E. S. R.*, 9, p. 907).

The sewage farms of the city of Freiburg, in Baden, O. KORNE (*Arch. Hyg.*, 32 (1898), No. 3, pp. 173-219, pls. 3, dgm. 1).—A chemical and bacteriological study of canals and sewage, with bibliography.

Report of the agricultural college at Aas, Norway, 1895-96, J. L. HIRSH (*Ber. Höiere Landbr. Skole i Aas*, 1895-96, pp. 331, pls. 6).

Technical education in Austria (*U. S. Consular Rpts.*, 1897, Dec., pp. 543-550).—Rise and development of technical schools in Austria.

Higher agricultural education in Denmark and Germany, J. SEBELIEN (*Ber. Höiere Landbr. Skole i Aas*, 1895-96, pp. 125-212).

Danish agricultural schools, T. FRÖST (*Aarsber. Offent. Foranst. Landbr. Fremme*, 1896, pp. 396-415).

On the introduction of apprenticeships in agricultural and dairy instruction, A. GRANSTRÖM (*Biet [Helsingfors]*, 18 (1897), Nos. 3, pp. 85-94; 4, pp. 106-122).

Danish agricultural institutions, N. HEYMAN (*Landbrugs-Institutioner.* Copenhagen: Nordisk Forlag, 1897).

Report of the agricultural department of Norway for 1896 (*Aarsber. Offent. Foranst. Landbr. Fremme*, 1896, pp. LIX+554).

Agricultural school at Spalato, Dalmatia (*Ztschr. Nahr. Untersuch. u. Hyg.*, 11 (1897), No. 14, p. 245).—An agricultural school is to be founded in Spalato, Dalmatia, with funds formerly given to the agricultural school in Gravosa, the latter being discontinued.

A brief handbook for apprentices on larger estates, A. V. TUXEN (*Kortfattet Vejledning for landrænselærlinge paa større Gaarde.* Copenhagen: Schubothe's Bogh., 1897, pp. 188).

The biological annual, 1895, Y. DELAGE (*L'Année biologique*, 1897, pp. XLVIII+732).—This publication is edited by Professor Delage, with the cooperation of a large number of well-known assistants. It is intended to give a review of all papers dealing with general biology.

NOTES.

ALABAMA COLLEGE STATION.—At the meeting of the board of trustees in June P. H. Mell was elected director of the station, and C. F. Baker, assistant zoologist, was given eighteen months' leave of absence, beginning January 1, 1899, to visit South America on a collecting expedition. Farmers' institutes were authorized under the control of the station council and Dr. C. A. Cary, veterinarian, was placed in charge of the work. An appropriation was made to defray expenses.

GEORGIA STATION.—The station has commenced to experiment this year in sugar-beet culture, and is continuing experiments on the use of lime upon dry and wet soils, the latter being first underdrained. On the dry soils so far no results are apparent from the use of lime applied last fall.

ILLINOIS STATION.—The station is cooperating with the Illinois State Sugar Beet Growers' Association, which was formed at the time of the sugar beet convention called by the station. Arrangements have been made for the publication of brief circulars upon various topics, issued in small numbers, and sent to the press of the State. These circulars serve sometimes to distribute information and sometimes to collect information from the people, and are proving of great value to the station work.

KENTUCKY STATION.—The board of control has been reorganized as follows: Chairman, Hart Boswell, Lexington; J. T. Gathright, Louisville; Thomas Todd, Shelbyville; James K. Patterson, Lexington, and secretary, M. A. Seovell, Lexington. A recent enactment of the legislature gives the station the supervision of the pure-food law of the State.

MAINE STATION.—The new poultry plant, consisting of a breeding house 150 ft. long and a winter brooding house 60 ft. long, was completely destroyed by fire May 18, involving a loss of about \$1,500.

MARYLAND COLLEGE AND STATION.—H. J. Patterson has been elected director of the station, *vice* R. H. Miller, resigned. The State legislature has appropriated \$14,000 for the erection of a Science Hall, to be used jointly by the college and station. It has also appropriated \$10,000 for inaugurating State work in entomology and vegetable pathology, and provided for an annual appropriation hereafter of \$8,000 for its maintenance. C. O. Townsend has been elected botanist and pathologist in the college and station and State pathologist.

NEW MEXICO STATION.—On June 17 the barn at the Las Vegas Substation was struck by lightning and completely destroyed, together with all its contents. The loss is estimated to be about \$2,500, excluding about \$600 worth of property belonging to the superintendent. The station carried an insurance of \$1,500 on the barn and property.

NORTH CAROLINA STATION.—George S. Fraps, a graduate of North Carolina College of Agriculture and Mechanic Arts and of Johns Hopkins University, has been appointed assistant chemist of the station.

NORTH DAKOTA COLLEGE AND STATION.—The board of trustees of the North Dakota Agricultural College have decided to discontinue the dormitory system and convert

the boys' dormitory into laboratories and class and lecture rooms, which will largely increase the college facilities of every department, particularly those of agriculture, horticulture, and veterinary science.

OHIO STATION.—The General Assembly has appropriated the following funds for the support of the station for the two years 1898 and 1899: Expenses of board of control, \$800; general repairs, labor, and supplies, \$6,000; bulletin illustration, \$900; substations for field experiments, \$5,600; special work in entomology, botany, horticulture, and chemistry, \$7,000; furniture and fixtures, \$1,200; and investigation of tuberculosis, \$1,000; making a total of \$22,500.

OKLAHOMA STATION.—OSCAR M. MORRIS, B. S., a graduate of the college in 1896, has been appointed assistant horticulturist, and A. G. FORD, B. S., a graduate of the college in 1898, has been appointed assistant in chemistry.

TEXAS COLLEGE.—L. L. FOSTER, of Velasco, has been elected president of the college. R. H. WHITLOCK, who has been acting president, will retire to the duties of professor of mechanical engineering.

UTAH COLLEGE AND STATION.—The following changes have been made in the governing board of the station: Allan M. Fleming, of Logan, has been elected treasurer, *vice* Ripley S. Lyon, resigned, and Mrs. R. N. Bagley, of Ogden, and Joseph Morrill, of Logan, have been appointed in place of John C. Graham and Clarissa S. McAlister. The other members of the board have been reappointed. Samuel Fortier, hydraulic engineer, has severed his connection with the station to accept the position of Superintendent of the Bear River Canal and Ogden Waterworks Company. George L. Swendsen, of the Brigham Young Academy, Logan, has been elected to succeed Professor Fortier. F. W. Brewer, biologist, has resigned his position in the college and station. The biological work of the station will be discontinued. W. S. Langton will next year assume charge of that department in the college.

WYOMING STATION.—During the year there have been constructed an addition to the greenhouse, 12 by 50 ft.; a small dwelling house upon the station farm, situated three miles from the university, and a small stable. The station is planning more extensive irrigation investigations than heretofore, and the results of a new alkali experiment are now ready for publication.

NECROLOGY.—Lyon Playfair died at London May 29, 1898, at the age of 79 years. He was one of the most prominent English scientists interested in agriculture, a pupil of Graham and later of Liebig. At one time he gave much attention to the problems of food and nutrition, his investigations in this line being of considerable importance. He was appointed professor of chemistry in the Royal Institution at Manchester in 1843. In 1844 Sir Robert Peel appointed Playfair on a commission to inquire into the sanitary condition of large towns. In 1856 he was appointed professor of chemistry at the University of Edinburgh and remained in this position for thirteen years. To him more than to any other is due the advance of technical education in England. He was actively engaged in the first and second great exhibitions in 1851 and 1862. He presided over many royal commissions and his great ability was generally recognized. He held many political positions, served in Parliament for a long period of years, and received the honor of a peerage. He was the last remaining original member of the London Chemical Society.

Osburt Salvin died at Hawksfold, near Haslemere, England, June 1, 1898, at the age of 63 years. He was a prominent ornithologist and entomologist and made many expeditions for collecting specimens, notably to Central America. In 1874 he accepted the office of the Strickland curatorship in the University of Cambridge, holding the position until 1883, when he resigned and, associated with Mr. Godwin, devoted himself to bringing out the "Biologia Centrali Americana." Alone or associated with others he was the author of some 124 scientific papers, among other work contributing Trochilidae and Procellariidae to the British Museum Catalogue of Birds.

EXPERIMENT STATION RECORD,

EDITED BY

A. C. TRUE, Ph. D., *Director*,

AND

E. W. ALLEN, PH. D., Assistant Director—Chemistry, Dairy Farming, and Dairying.
W. H. BEAL—Meteorology, Fertilizers (including methods of analysis), Soils, and
Agricultural Engineering.

WALTER H. EVANS, PH. D.—Botany and Diseases of Plants.

C. F. LANGWORTHY, PH. D.—Foods and Animal Production.

F. C. KENYON, PH. D.—Entomology and Veterinary Science.

R. A. EMERSON—Horticulture.

J. I. SCHULTE—Field Crops.

With the cooperation of the scientific divisions of the Department and the Abstract
Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. X, No. 2.

	Page.
Editorial notes: Agricultural experiment stations in Japan.....	101
Physical and meteorological researches, principally on solar rays, made at the station of agricultural climatology at the observatory of Juvisy, Camille Flammarion	103
Recent work in agricultural science	115
Notes	199

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

Sulphuric acid as a reagent in the analysis of fatty acids, E. Twitchell.....	115
Needed reform in the analytical methods for fodders and feeds, E. Schulze....	115
Report of the chemist, R. C. Kedzie	116

BOTANY.

Root tubercles and their production by inoculation, D. H. Otis	119
Concerning Alinit.....	120
The ash of epiphytes, R. C. Kedzie	120
Report of the botanist, C. F. Wheeler	121

FERMENTATION—BACTERIOLOGY.

The unorganized ferments, or enzymes, concerned in the brewing and distilling industries, I. O'Sullivan.....	122
Red yeasts, Katherine E. Golden and C. E. Ferris.....	122

METEOROLOGY.

	Page.
Monthly Weather Review, Vol. XXVI, Nos. 1-3	124
Arizona weather and climate, E. M. Boggs and N. H. Barnes.....	124
Meteorological observations at Michigan Agricultural Experiment Station, 1895, R. C. Kedzie	124
Forecasts of frosts, R. C. Kedzie.....	125
Monthly reports of the River and Flood Service, W. L. Moore and P. Morrill.	125
Wrecks and casualties on the Great Lakes during 1895, 1896, and 1897, W. L. Moore and N. B. Conger.....	125

WATER—SOILS.

Drinking waters, E. F. Ladd.....	129
The Beeville Station: Soils, climate, water supply, and irrigation equipment, J. H. Connell and S. A. McHenry.....	125
Investigations on the influence of the physical properties of soils on the growth of crops, E. Wolluy.....	128
Relative sensitiveness of plants to acidity in soils, W. Maxwell	128
Soil humus, E. F. Ladd	129
The objects and methods of soil analysis, E. W. Hilgard	129

FERTILIZERS.

The fertilizer industry, J. Hyde and G. K. Holmes.....	130
Investigations on manure at Lauchstädt, 1896-97, M. Maereker and W. Schneidewind.....	132
On the losses of ammonia which take place in the preparation of barnyard manure, P. P. Delcraïn	133
Potash: Its commercial and agricultural relations and a chemical method for its accurate estimation in soil, A. T. Neale, W. H. Bishop, and C. L. Penny..	134
Analyses of licensed commercial fertilizers, F. W. Woll.....	136
Composition of commercial fertilizers, H. B. McDonnell et al.....	136
Commercial fertilizers, H. A. Huston and W. J. Jones, jr	136
Commercial fertilizers, B. H. Hite	136
Analyses of commercial fertilizers, B. W. Kilgore.....	136
Fertilizers, J. H. Stewart and B. H. Hite.....	136

FIELD CROPS.

Some experiments in corn raising, C. D. Smith.....	136
Fertilizer, culture, and variety experiments on corn, R. J. Redding	138
Fertilizer, culture, and variety experiments on cotton, R. J. Redding	139
Hops, R. H. McDowell.....	147

EXPERIMENT STATION RECORD.

VOL. X.

No. 2.

A recent communication from Mr. S. Machida, of Japan, contains some interesting information in relation to the status of the experiment station enterprise in his country. Mr. Machida was formerly connected with the station at Tokyo, but is now director of the recently established Tokai station, situated in Aichi.

The experiment stations in Japan are an outgrowth of the investigations and field experiments carried on in connection with the Imperial College of Agriculture at Tokyo. Their service to agriculture was recognized by Japanese agriculturists and created an interest in agricultural experimentation, resulting in the establishment of agricultural institutions at Yokaichi and Kioto. In April, 1893, a bill passed the Japanese Parliament providing for the establishment of seven experiment stations under the control of the department of agriculture and commerce. These consist of a central station at Tokyo and six branch stations located by the minister of agriculture and commerce. These branch stations were located at Osaka, Miyagi, Ishikawa, Hiroshima, Tokushima, and Kumamoto. The work of these stations consists of tests of varieties of agricultural plants, selection of seed, tillage and culture, the use of fertilizers, soil investigations, harvesting and curing crops, agricultural technology, plant diseases and injurious insects, the protection of beneficial insects, feeding of farm animals, addressing farmers' meetings, distribution of seeds and plants, and analyses of miscellaneous materials sent in by farmers. The stations also answer questions propounded by farmers, make investigations of the present condition of Japanese agriculture, and publish records of the results of their work.

In 1896 three new stations were established on a much larger scale than the branch stations established in 1893. The locations of these stations are Aichi, Akita, and Shimane.

All of the stations, both old and new, are carrying out their work in accordance with the same general regulations and under the control of the central station, which is in charge of Mr. J. Sawano.

The Tokai station, located in Aichi, is a typical representative of the Japanese stations. It has a field of about 3.48 hectares ($8\frac{2}{3}$ acres), regular in form, with an irrigation ditch running through the center.

Originally the tract was very uneven, but it has been leveled off and made more suitable for experimental purposes and laid out into regular plats. It is now divided into four large portions. The land on one side of the irrigation ditch is paddy soil, and that on the other is dry land. In the "dry" field there are 198 plats, separated by a passage-way varying in breadth from 2 to 9 feet. The plats are connected with irrigation and drain ditches. The paddy field is divided into eight plats by roads and ditches, two ditches being used for irrigation and three for drainage. These plats can easily be temporarily subdivided into smaller ones. The station has been provided with eleven buildings used for office and laboratory purposes, storage, residences of officials and of workmen and servants, stables, etc.

The principal lines of work now in progress at the Tokai station are pot experiments on the availability of various forms of nitrogen and phosphoric acid to the rice plant; determination of the availability of nitrogen in organic nitrogenous fertilizers; influence of soil and manure upon rice; availability of natural sources of nutrients to different plants; effect of soil and fertilizers on the properties of the grain, straw, etc., of the rice plant; the effect of various forms of nitrogen on the production of indigotin in the leaves of *Polygonum tinctorium*; chemical investigations on the rice plant; the changes of coloring matter and composition of the indigo plant during its growth; the preparation of indigo and of dyestuffs from *Polygonum tinctorium*, and the chemical changes which take place during the process, and methods of analysis; various field experiments on paddy and upland rice—variety tests, use of seeds of different specific gravity, treatment of seed before sowing, time of sowing, distance, methods of manuring, etc.; variety tests of grasses and leguminous plants; variety, culture, and fertilizer experiments with sweet potatoes; variety, culture, and fertilizer tests with Japanese and upland cotton, and similar experiments with the indigo plant. In addition to the above, important investigations are being conducted in the chemical and microscopical laboratory.

The systematic organization of agricultural research in Japan is of especial interest at a time when this country is called upon to consider measures for the development of island regions where agriculture has hitherto been conducted in accordance with comparatively primitive methods. Evidently Japan has decided that the aid of science should be sought in a broad way to investigate the problems of her agriculture and has appreciated the fact that the progress of agriculture, as well as of other industries, depends very largely on scientific investigations and technical education. The Japanese experiment stations are attacking vital problems relating to the agriculture of that country, and the great usefulness of their work is illustrated by the publications which these stations have already issued. It is believed that we may learn much of value from this enterprise of the island empire of the East.

PHYSICAL AND METEOROLOGICAL RESEARCHES, PRINCIPALLY ON SOLAR RAYS, MADE AT THE STATION OF AGRICULTURAL CLIMATOLOGY AT THE OBSERVATORY OF JUVISY.

CAMILLE FLAMMARION,
Director of the Station.

The purpose of the station of agricultural climatology is to study the sun's rays and their action upon the phenomena of plant growth. The observatory at Juvisy is constantly engaged in observing the sun and its changing surface. It measures the size of the sun spots and tries to fix the astronomical bases upon which rest the relations between the variations in terrestrial temperature and the source of all the heat and light of the earth. The station studies the absorption of heat and light rays by plants, and analyzes the action of the different colors of the solar spectrum. It observes also the different transformations of the energy of the sun on which depends so intimately the entire terrestrial life.

SOLAR RAYS AND THE DEVELOPMENT OF PLANTS.

Special attention has been given to the study of the peculiar action of the sun upon vegetation. The relative efficiency of the light rays, the heat rays, and the chemical rays has been studied. In this respect the slow rays of the extreme red of the spectrum differ widely from the rapid rays of the extreme violet. The rays which exercise the most favorable influence upon certain phenomena of vegetable life are readily investigated. For such investigations hothouses were built at the station. The glass used was subjected to a careful spectroscopic examination. Blue glass, approaching closely to violet, was obtained, which was only traversed by the rays of the extreme right of the spectrum. The red glass was almost monochromatic and was only traversed by a little orange. The green glass gave least satisfaction. The three hothouses were placed close together under the same meteorological conditions. Adjoining the houses which were covered with colored glass was an ordinary hothouse, for comparison, with full illumination. The houses were ventilated by a current of air passing from south to north through them, the object being to provide as nearly as possible natural conditions and to avoid overheating. The temperature of the air in the different hothouses was observed and the quantity of the sun's heat which traversed them was measured. The accompanying table

shows the temperatures observed in the different houses on August 20, 1895:

Temperature of interior of hothouses with white and colored glass.

Time of day.	White.	Red.	Green.	Blue.
	<i>Deg. C.</i>	<i>Deg. C.</i>	<i>Deg. C.</i>	<i>Deg. C.</i>
7.30 a. m	32.0	31.0	30.7	29.5
8.30 a. m	40.0	39.5	37.0	35.0
10.30 a. m	49.0	46.0	41.5	40.0
12.30 p. m	42.0	40.0	39.0	38.0
2.30 p. m	41.0	40.5	40.3	40.2
4.30 p. m	30.0	30.0	30.0	30.0

From the above table it will be seen that the temperature of the hothouses decreased as the extreme right of the spectrum was approached. The temperature was the same in all the hothouses during cloudy days or when they did not receive the sun's rays directly. The decrease of the temperature in the blue house, as compared with the white, is explained by the fact that the absorptive power of the glass of the hothouses increased as the violet extremity of the spectrum was approached. The ability to absorb the sun's rays determines the heat in the hothouses. All rays traverse the white glass, and it is therefore in this house that the highest temperature was found. On the other hand, blue glass has the greatest absorbing power, and the hothouse covered with blue glass had therefore the lowest temperature.

In 1895 sensitive plants, grown from the same lot of seed and equally vigorous, were placed in each hothouse. Their height at that time was 0.027 meter. The plant placed in the red house developed extraordinarily and attained a size fifteen times as great as that in the blue house, where the plants remained nearly stationary. The red light produced the effect of a chemical fertilizer, although in this case actinic rays were absent. These plants were all equally cared for. The sensitiveness of the plant grown in the red house had attained such a degree that the slightest movement or breath was sufficient to cause the closing of the leaflets and the drooping of the pedicels. The sensitiveness diminished under the white or green color, while under the blue light the plant was almost insensitive. The plant in the red house blossomed September 24. In the white house it increased in stockiness and was very vigorous but did not increase in height. It showed flower buds, but they did not open. The plant under the red glass had a lighter-colored foliage than that under the white. The foliage was paler than that under the green, while the blue was much darker. The difference of the temperature between the hothouses was not very great. There were, nevertheless, several degrees difference between the white and the blue. The intensity of illumination decreased in the same proportion as the temperature rose. The height of the plants in the different houses after an experiment of 3 months was relatively as follows: Blue hothouse, 0.027 meter; white hothouse, 0.1 meter; green hothouse, 0.152 meter, and red hothouse, 0.42 meter.

A photograph taken October 22 shows at a glance the influence of different solar rays (fig. 2). The difference observed might have several causes, viz: (1) The difference in the solar rays admitted; (2) difference in temperature which, compared with that in the white house, was lowest in the blue and highest in the red house; (3) difference in the amount of light, the intensity of which was greatest in the white hothouse and least in the blue; and (4) to difference in humidity of the soil and the air, which was lowest in the white hothouse and highest in the blue.

It would be interesting to know whether the results obtained are due to these differences. If the differences depend upon temperature, they would differ according to the seasons. In the spring the temperature of the hothouses during daytime remains below the optimum for the growth of plants. The amount of growth, therefore, would follow in this order: White, red, green, and blue; and during the summer, when the temperature often surpasses the optimum for plant growth, the maximum of growth would occur in the inverse order, namely: Blue, green, red, and white. The blue hothouse, the temperature of

FIG. 2.—Sensitive plants grown in different colored light.

which is nearest the optimum, should favor the greatest growth. On the contrary, the results obtained in the different houses were absolutely identical in spring and summer, notwithstanding the difference in temperature. The greatest development was always produced in the red hothouse, and the minimum in the blue, where there was almost no growth. The results indicate that the inequality in growth is not due to differences in temperature. The sensitive plant in the white hothouse owes its feeble growth to the combined action of excessive light and temperature.

In 1896 experiments were begun to compare the development of

plants in white and red light under the same temperature and the same intensity of light. The same temperature was obtained in the different houses by means of screens of loosely woven white linen, which allowed only a limited passage of the sun's rays but which did not alter the quality of the rays. The subjects of the experiments were sensitive plants, maize, peas, beans, lettuce, strawberries, fig-trees, Achyrantha, Perilla, Coleus, Strobilanthes, Tradescantia, grapes, etc. Some of the most interesting results are appended. On June 13 three pots of equally vigorous sensitive plants, 0.03 meter in height, were placed in each hothouse. Their increase in height at different dates is shown in the following table:

Height of sensitive plants in different colored hothouses.

Date.	Red.	White.	Green.	Blue.
	<i>Meter.</i>	<i>Meter.</i>	<i>Meter.</i>	<i>Meter.</i>
June 13	0.030	0.030	0.030	0.030
July 22230	.120	.080	.035
August 16380	.240	.100	.035
August 30470	.270	.100	.035
October 12500	.280	.100	.035

The sensitive plant in the red hothouse attained a greater height and

was more sensitive than that in the white hothouse, and its vegetative development was more advanced. It began to bloom October 1, while the plant in the white hothouse began October 12. The sensitive plant in the green hothouse remained almost at a standstill, became etiolated and, the nutrition becoming insufficient, the plant ceased to grow. The plants in the white hothouse, grown under the same conditions of temperature, moisture, and

FIG. 3.—Sensitive plants grown at the same temperature in different colored light.

illumination as those of the red hothouse, attained a height of only

0.28 meter, while those in the red hothouse reached 0.5 meter. A photograph taken October 12, 1896 (fig. 3), shows the differences in growth under similar temperatures. It will be noticed that the sensitive plant in the white hothouse had gained in stockiness what it had lost in height. Indeed, the diameter of the stem and the surface of the leaves were larger in the plants in the white hothouse than in those in the red. The weight of the above-ground part of the plants of the different hothouses was as follows:

Effect of different colored lights on the weight of sensitive plants.

Hothouse.	Weight of stems and leaves.	Weight of an average leaf.	Diameter of stem.
	Grams.	Gram.	Mm.
White.....	8,400	0.600	3.0
Red.....	4,600	.250	2.0
Green.....	.300	.150	1.5
Blue.....	.150	.095	1.0

It will be seen that, notwithstanding the great height of the sensitive plant grown under red glass, its weight is about half that of the plant grown in the white hothouse.

In experiments with other plants results were obtained which differed somewhat according to the species. The results with *Strobilanthes dyerianus* agreed entirely with those for the sensitive plant.

Young summer lettuce was placed in different hothouses during June and July. The results in the white hothouse and in the open air were identical. The leaves were large, thick, of a reddish-brown color, and formed a well-rounded head. The lettuce in the red house was drawn, the leaves were long and straight, blanched, drooping, and widely separated by long internodes. The plants in the green house increased in height a little, while the leaves were less curled than those in the red house. The lettuce in the blue house added only a few leaves, without growing at all in height. The height attained by the different plants was as follows: In the red house, 1.5 meters; in the white, 0.6 meter; in the green, 0.4 meter; in the blue, 0.1 meter. The lettuce in the red house bloomed 15 days earlier than that in the white house. Figure 4 (p. 108) shows these differences.

In the experiment with maize, young stalks measuring 0.15 meter in height were set out in the hothouses in May. They were measured July 22 with the following results: In the white hothouse, 1 meter; in the red, 0.4 meter; in the green, 0.2 meter; in the blue, 0.15 meter. These results differ from those observed in the case of the sensitive plants in that the development of maize was less in the red hothouse than in the white.

In the experiments with peas and beans the most vigorous growth occurred in the white hothouse. There was less development in the red, and the minimum of growth was obtained in the blue hothouse.

The beans bloomed and fruited in the white as well as in the red hot-house, but perished in the green and blue. Peas bloomed in all hot-houses except the blue, where the plant did not grow any during the two months of the experiment. The peas in the green house remained in bloom for three weeks without fruiting. Only those in the red and white houses fruited.

The following assortment of vines was placed in each of the hothouses: One of Chasselas, two of Frankenthal, and two of Mélinet. The Chasselas, and one vine of Frankenthal, were planted in 1894, the vines of Frankenthal and Mélinet, in 1895. Beginning with April 10, a differ-

FIG. 4.—Lettuce plants grown in different colored light.

ence in development could be noticed, due to the unequal temperature of the hothouses. The vines in the white and red houses started earliest. The growth of stem and number of leaves of a Mélinet in the different houses (May 10) is given below:

Growth of grapevines under colored glass.

Hothouse.	First branch.	Second branch.	Third branch.	Number of leaves.
	<i>Meter.</i>	<i>Meter.</i>	<i>Meter.</i>	
Red.....	0.80	0.83	16
Green.....	.48	.02	8
Blue.....	.50	.45	0.18	16
White.....	.20	.20	12

The results with the Frankenthal were absolutely the same. There was an extraordinary development of branches in the red house, surpassing the white in this respect. This difference was greatly increased by pinching off the branches. The plants in the green light soon stopped growing and made only a few new leaves. The plants in the blue house continued to grow slowly. To recapitulate: The vine in the white house grew but slowly; its wood was well developed; it remained short and vigorous during the entire season. The vine in the red house grew in length, but lost much in vigor; its numerous branches had frequently to be pinched back, and its foliage was but little colored. The vine in the blue house grew slowly, considering the rapid start made; it remained vigorous with large dark-green leaves. One year-old vines behaved in the same manner; the vines in the white hothouse were vigorous and developed a more luxuriant growth than those in the other houses. In general, the phenomena in case of the grapes were similar to those observed in the case of sensitive plants. However, the blue rays were not so unfavorable to the development of the vine as they were for other plants. The experiments with vines were concerned only with the vegetative growth, and not with the fruiting.

The development of *Perilla* was intense in the white and red houses, the plants in the white surpassing in vigor those in the red. The plants in the green house changed little during the experiments, while those in the blue remained inactive.

Experiments with *Coleus* showed little difference in growth. The plant in the white hothouse spread and made a magnificent ornamental plant. That in the red house, while showing less foliage, increased in height. In the green and white houses there was very little development.

The results with *Achyrantha* accord with those for the sensitive plant. The plant in the red house grew so much in length that its branches could hardly hold up.

Three young potted strawberry plants of the same age and vigor were placed in each hothouse in May. In June the plants fruited with the following result:

Effect of different colored light on fruiting of strawberries.

	Number of fruits.	Total weight of fruit.	Average weight of fruit.
		Grams.	Gram.
In the open air	70	46.40	0.66
In white hothouse	73	46.80	.64
In red hothouse	25	9.80	.39
In green hothouse	12	4.20	.35
In blue hothouse	5	1.80	.36

Only the plants in the white hothouse and those in the open air produced any considerable number of fruits. The plants receiving the total radiation yielded five times as many fruits as those which grew

under the red light. Those in the green hothouse yielded about one-tenth as much as those in the white. The weight of the fruits from the blue hothouse was insignificant. The strawberries which received only colored light were very watery and insipid. Their average weight was half that of those which had received the total radiation.

The different rays of the solar spectrum modify not only the above-ground growth of plants, but also affect the entire vegetative part of the plant. The root system of the young plants which had been grown in hothouses was poorly developed. It was greatly reduced in the red house, and in the blue there was almost no root system. The weight of the roots of the sensitive plants in the different houses, October 13, was as follows: In the white house, 5 gm.; in the red, 1.6 gm.; in the green, 0.09 gm.; in the blue, 0.05 gm.

The nutrition of the plant is to a great extent dependent upon the root system. It is partly due to this dependence that the plants in the red, blue, and green houses had so little vigor. It is well known that the red and orange portions of the spectrum favor assimilation, transpiration, and respiration of plants. The natural result of this is an increase in the vegetative activity and in the function of nutrition. It is evident, therefore, that differences of growth, vegetative activity, vigor, development, sensitiveness, and coloration of plants result from differences in radiation. Microscopic examination of sections of the sensitive plant showed that the anatomical structure and the diameter of the plants in the red and white houses differed. The epidermis was thicker, and the woody fibers of the stem were more numerous in the plant in the white hothouse, the pith was much less developed, the cells were better formed, and the partitions thicker.

Notwithstanding the great care which was taken in conducting these experiments, it was very difficult to avoid all sources of error. Glass considered monochromatic for the red as well as for blue proved unsatisfactory for the reason that some yellow rays passed through them. In further study of this subject, experiments were conducted in which the three different colors were obtained from the spectrum derived from a prism.

Plants were placed in the different regions of the solar or electric spectrum and the modifications due to different rays thus observed. For this purpose a prism was constructed capable of giving a spectrum of great dimensions, and in which could be placed such liquids as carbon bisulphid and spirits of turpentine, the refractive power of which is very high. The source of light was an electric arc lamp. The use of carbon bisulphid was discontinued on account of its volatility and excessive inflammability, and as a substitute spirits of turpentine, the refracting power of which is far less, was used. The index of refraction for spirits of turpentine is 1.470496 for the red and 1.493874 for the violet. The difference in dispersion of the two is, therefore, 0.023378. A straight slit was placed against the prism filled with turpentine and

a convex lens placed between the prism and the arc lamp. These were placed at a distance from the prism equal to double that of the focus of the lens. The prism was placed in the position of least deviation to the spirits of turpentine, which was in this case 30° . The spectrum reflected upon a screen 3 meters from the prism measured about 25 cm. (nearly 10 in.) in length. The arc light gave a constant intensity of 10 amperes and burned twenty hours daily. Notwithstanding the limited size of the spectrum a series of experiments was started, which permitted the verification of the results obtained in the colored hothouses. These experiments were on the growth of flax and vetches, and on the transpiration of leaves.

August 25 a small box of flax was exposed to the luminous region of the spectrum. The plants had sprouted and reached a height of 0.04 meter, and the cotyledons were slightly expanded. On August 27 the first leaves were beginning to expand in the red portion of the spectrum, and some leaves appeared in the yellow, but no change was observed at the right end of the spectrum. On September 4, ten days after the beginning of the experiments, the box with the plants was photographed and the plants were measured. In the red light the stems had attained a height of 0.085 meter, and in the blue 0.040 meter.

The temperature remained the same for all plants during the time of experiment; it varied between 10° and 30° , with an average temperature for the ten days of 18° C. On account of great difficulties encountered the experiments had to be discontinued. They were continued far enough to verify the favorable action of the red rays upon the growth of plants. This favorable action seems to be due partly to the infra-red rays. The pure green of the spectrum was very small, and on this account plants exposed to green rays received some yellow rays. The use of carbon bisulphid would have provided a more extensive spectrum.

The common vetch (*Vicia communis*) is very sensitive to light, and grows very rapidly under a weak illumination. Pots of three plants each were placed in different portions of the spectrum and separated by small black screens. At the commencement of the experiment their height was 0.04 meter. The average height of the plants in each pot August 15 was as follows: Red 0.09, yellow 0.08, green 0.05, violet 0.07; and August 20, red 0.21, yellow 0.185, green 0.16, violet 0.15 meter. As in the other cases, the maximum growth took place in the red portion of the spectrum, the results obtained with the spectrum of the electric light and in the hothouses with colored glasses agreeing.

EFFECT OF WHITE AND COLORED LIGHT ON TRANSPIRATION.

In the course of the above experiments the transpiration of the leaves under different rays of the spectrum was measured. It was found that grapevines attained the maximum of transpiration in white light, there being a decrease from red to blue. An experiment on leaves of maize exposed to different regions of the luminous electric spectrum gave

more definite results. The maize plants were fifteen days old; the stems were equally vigorous, and each bore five leaves. The experiment was begun September 14, with an average temperature of 20° C., and each leaf was inclosed in a glass tube. The experiment lasted 26 hours, and the transpired water was as follows:

Effect of different colors on transpiration of maize.

Color.	Weight of leaf.	Weight of transpired water.	Water transpired per gram of leaf.
	<i>Gram.</i>	<i>Gram.</i>	<i>Grams.</i>
Red	0.135	0.208	1.540
Yellow102	.230	2.254
Green with some yellow rays095	.065	.682
Violet080	.024	.302

It will be seen that the maximum transpiration occurred in the orange-yellow and the minimum in the violet portion of the spectrum.

ACTION OF DIFFERENT PORTIONS OF THE SPECTRUM ON THE COLOR OF VEGETABLE TISSUES.

The many different colors of plants are mostly due to light. The green color of the leaves, due to chlorophyll, can only be produced in the light. The blue, yellow, red, and other colors are partly due to pigments and partly to cell sap. The writer has investigated the rôle of light in the coloration of the different tissues of flowers, fruits, etc.

For these researches colored-glass hothouses and absolutely monochromatic solutions were used. The solutions were contained between the walls of special vessels in the interior of which the flowers, fruits, leaves, etc., were exposed. The red was obtained from a solution of carmin in ammonia, the green from a concentrated solution of copper chlorid, and the blue from a solution of copper sulphate and ammonia. According to Sachs, the development of the coloring matter is independent of the action of light. It is developed in the leaves at the expense of substances which are produced under the action of light. The author's experiments indicate that light acts not only on the nutrition of the plant, but also on the coloring of the tissues. It sometimes exerts a direct action on the flower, and in this case the coloring is due principally to light.

Plants may be classified according to the cause of coloration into three groups, namely, those in which coloration is due (1) to the direct action of light, (2) to the action of the light and to the food material in the leaves, and (3) to other causes than the action of light. Chlorophyll is directly due to the action of light. It is not immediately destroyed when the plant is placed in darkness, but remains unchanged as long as the plant has not exhausted its reserve, disappearing only when the reserve material has been exhausted. Observations on

ACTION OF DIFFERENT LIGHT RAYS ON COLEUS LEAVES.

A, full radiation; B, red rays; C, green rays; D, blue rays; E, open air; F, subdued light; G, diffused light; H, very dim light.

flowers are to the same effect. It has been known for some time that to obtain white lilacs it is only necessary to place colored lilacs, especially the Marly variety, in a hothouse kept at a constant temperature of 15° C. Duchartre states that the lilac would become white if placed in a very light hothouse if the temperature remained constantly at 15° C. He attributes the decoloration of the flowers to the more energetic oxidation of the air of the hothouse.

The experiments of the author were conducted on Marly and Persian lilacs, planted in colored hothouses and in the open air. The panicles were budded and at the time of planting were slightly colored. In the white hothouse the lilacs became pink and almost entirely lost their color. In the red, green, and blue houses they become absolutely white. The hothouses had a varying temperature, during the night falling to 1° and rising during the day to 25° . Lilac buds inclosed in a dark hood become discolored notwithstanding the temperature was the same as in the surrounding air. If the panicles were inclosed when already more or less colored red shades were obtained. Thus it is possible to obtain on one stem flowers of all shades between the white and violet red. If panicles already colored are placed under a colored bell jar, flowers varying from pale blue to clear red violet will be obtained. These results are neither due to temperature nor to activity of growth, but are evidently caused by differences in light.

The writer's experiments covered a great number of plants, and it was found possible to change the form, size, and color of the leaves of plants with different colored light. Among the most remarkable results were those obtained with the Coleus. In the accompanying plate some of the differences observed on this plant due to its culture, character of solar rays, or the different intensity of light are shown.

In Plate I, A represents a leaf exposed to full radiation in the white hothouse, and B one grown in the red hothouse. It can be seen that the red pigment decreased in red light, the leaf spread, and its form changed. Leaf C, grown under the green-colored glass, is diminished in size, the red pigment has disappeared, being replaced by a yellow coloration. In leaf D, grown in blue rays, the red pigment has almost completely disappeared. On the same plate are also shown four other leaves of Coleus, the first grown in the open air, the second under a slightly diffused light through a garden frame, the third in diffused light, and the fourth under a still weaker light. The transformation of the plant in this case is gradually accomplished under an attenuation of light, as in the preceding case under the influence of different rays. The largest and most curious leaf is the third. The fourth was greatly diminished and modified, having changed from poppy red with a dark edge to yellow and light green.

Comparing these eight Coleus leaves it will be seen that the leaf from the hothouse under total radiation has developed much more than the one grown in the open air; that those from the red house and diffused

light show increased size and a particular coloring; and that those from the green and blue hothouses and under very feeble light have lost almost all their resemblance to the normal leaf. These experiments establish the fact that light, without the aid of any other factors, is able to modify plants.

Results not less curious have been obtained with other plants, some of which are shown in the colored plate (Pl. II). The red-flowered crassula was placed in the dark at a time when its buds were only slightly colored. It shows only a narrow, colored edge bordering a white flower. The purple leaves of *Alternanthera amena* became absolutely green under the red glass. Geranium leaves lost their reddish-brown tone and changed under the red, blue, and green rays into the three following forms: In the red hothouse they were large, well cut, and pale green; in the blue, almost round and dark green; in the green, small and very pale green. Similar experiments were made with fruits by surrounding the branches with colored glasses. The same results as indicated above were produced with peaches, apples, cherries, and strawberries. In certain plants the leucites, to which their coloration is due, act according to the way in which they receive the light. Others vary under the influence of light in combination with the plant's nutrition. Still others are altogether insensible to the action of light. To the last class belong carrots, beets, radishes, potatoes, truffles, etc., the underground colorations of which are evidently independent of light.

[Concluded in next number.]

ACTION OF DIFFERENT LIGHT RAYS ON THE COLORATION OF PLANTS.
 1, Red-flowered crassula: (A) in sunlight; (B) in darkness. 2, *Alternanthera amara*: (C) full radiation; (D) red rays. 3, Geranium leaves; (E) full radiation; (F) blue rays; (G) green rays; (H) red rays.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY

Sulphuric acid as a reagent in the analysis of fatty acids, E. TWITCHELL (*Jour. Soc. Chem. Ind.*, 16 (1897), No. 11, pp. 1002-1004).—The reaction between concentrated sulphuric acid and any fat involves chiefly the unsaturated fatty acids of the fat and consists primarily of the addition of sulphuric acid to the unsaturated carbon atoms of these acids. On this assumption the author concluded that a separation of the unsaturated oleic, linoleic, and linolenic acids from the unattacked saturated palmitic and stearic acids could be made and possibly a difference in the action of sulphuric acid in the different members of the group of unsaturated acids might then be shown. The following tentative method was adopted: Weigh from 0.5 to 1 gm. of the fatty acid in a glass-stoppered Erlenmeyer flask; melt and allow to solidify in as thin a layer over the bottom as possible. On the layer pour about 3 cc. of 85 per cent of sulphuric acid. There is usually no combination until the flask has been slightly warmed. At a certain temperature the combination takes place very rapidly and forms a clear solution. When this occurs the flask is quickly cooled, 50 cc. of petroleum ether added, the stopper inserted, and the flask shaken violently for a minute or two, then allowed to settle and the petroleum ether decanted. The flask is rinsed twice with 10 cc. of petroleum ether, the washings added to the first extract, and the whole poured into a separatory funnel and washed once or twice with water. The petroleum ether is then evaporated, and the residue, consisting of the saturated fatty acids, is weighed.—J. P. STREET.

Needed reform in the analytical methods for fodders and feeds, E. SCHULZE (*Landw. Vers. Stat.*, 49 (1898), No. 6, pp. 419-441).—The author calls attention to the impurity of the ether extract obtained from feeds in the ordinary analysis and the inaccuracy of the methods for crude fiber. None of the present methods for fiber are accurate for all classes of fodders and feeds. He suggests that after the material is dried and finely pulverized it be extracted with ether, alcohol, malt extract, and water. This will bring into solution the fats, lecithin, soluble carbohydrates, starches, amids, soluble proteids, etc. The insoluble residue will consist of the insoluble proteids, the cell walls, and a part of the ash constituents. By determining and deducting

the ash and protein content of this residue there would remain the nitrogen-free material insoluble in the above-named solvents. The method as suggested is simpler and easier of manipulation than that suggested by König.¹—J. P. STREET.

Report of the chemist, R. C. KEDZIE (*Michigan Sta. Rpt. 1896*, pp. 128-131).—A general summary of the work of the chemical department during 1896, including more detailed notes on the ash of epiphytes (noted elsewhere) and the danger resulting from the use of Paris green against insects on peppermint. A chemical examination of the oil distilled from peppermint plants sprayed with Paris green gave distinct reactions for arsenic.

Report of the agricultural chemical laboratory at Helsingfors, Finland, for 1895 (*Landtbr. Styr. Meddel., 1897*, No. 19, pp. 130-139).

On E. Salkowski's investigations on the effect of heating albumen in water under pressure, R. NEUMEISTER (*Ztschr. Biol., 36*, No. 3, pp. 420-424).—This is a controversial article.

The cleavage products of albumin, I, O. FOLIN (*Ztschr. Physiol. Chem., 25*, No. 1-2, pp. 152-164).

Contribution to the study of the albuminoids of flour of legumes and cereals, E. FLEURENT (*Compt. Rend. Acad. Sci. Paris, 126* (1898), No. 19, pp. 1374-1377).—According to the author, bean flour contains 31.01 per cent total nitrogenous material, made up of 18.92 per cent legumin, 0.2 per cent albumin, and 11.92 per cent gluten. The gluten consists of 9.52 per cent glutenin and 2.40 gliadin. The so-called vegetable casein is regarded as legumin and glutenin and vegetable fibrin as albumin and gliadin. The properties of nitrogenous constituents are briefly discussed, as well as the use of bean flour with wheat flour for bread making.

BOTANY.

Root tubercles and their production by inoculation, D. H. OTIS (*Industrialist*, 21 (1898), No. 6, pp. 363-378, pl. 1, figs. 2).—The author makes a general statement relative to the presence and function of tubercles on the roots of leguminous crops, and reviews the earlier as well as more recent investigations relative to them. He also reports investigations on root tubercle development of soy beans.

Soy beans have been grown at the Kansas Station since 1890, but frequent examinations of the roots failed to reveal the presence of any tubercles on them. The author secured from the Massachusetts Station a quantity of soil in which soy beans had been grown and tubercle development previously noted. Two varieties, yellow and medium green soy beans, were grown and different methods of inoculation practiced. In some of the plats a small quantity of inoculated soil was placed in each hill at the time of planting. In others an extract of the soil was made and this used for inoculation. The methods of culture and details of growth are given, in which it appears that the rows inoculated at the time of planting attained on the whole a little greater height than those inoculated with the extract after planting; the difference, however, was slight. All the inoculated plants showed a fairly uniform distribution of tubercles as well as a greater diameter of the lower part of the stem than the plants not so treated. Analyses of the crop showed a slight increase in nitrogen, protein, and water content. The yellow soy beans inoculated with the extract gave the largest yield of both beans and fodder, while the medium green not treated yielded the greatest quantity of beans, and the plat inoculated with soil the most fodder.

The field experiments were repeated in pots and extended to include a number of varieties of soy beans, and all plants inoculated either with soil or extract showed well-defined tubercles on their roots. The author undertook experiments in the greenhouse to ascertain the time of tubercle appearance. The first visible tubercles appeared thirteen days after the beans were planted, or eight days after the plants were above the ground. The effect of sterilizing the soil was noted, the Kansas soil being already sterile and the Massachusetts soil having been heated to 200° C.

Experiments in which the plants were inoculated at the top, middle, and bottom of pots showed that the organism producing the tubercles is incapable of very great vertical distribution throughout the soil. In order to secure proper distribution, a mechanical mixing of the soil is necessary. Inoculation experiments, in which different amounts of infected soil were used, showed no particular difference, either in the development of the plants or the tubercles on the roots. The action of light on the micro-organism was found to be without any appreciable effect. The effect of different temperatures on the inoculating material was tested, in which soil was heated to ten different points, varying from

40 to 150° C. Somewhat similar experiments were made in heating the soil extract, and it was found that the tubercles develop best at the lower temperatures and seem to decrease as the temperature increases. In pot experiments, in which adzuki beans, cowpeas, Canada field peas, alfalfa, and red clover were planted and inoculated with Massachusetts soil, no tubercles appeared on the roots of the adzuki beans or the cowpeas: the alfalfa showed a few, while on the clover and Canada field peas they were very numerous. This seems to show that the form of the organism causing the tubercles on the different plants varies.

Microscopic studies were made of sections of the soy-bean tubercle, and investigations made on the extent of the distribution of the micro-organism of the soy bean tubercle in the United States. It was found to be indigenous in the States of Indiana, Louisiana, Massachusetts, North Carolina, Rhode Island, and Tennessee, and has been established by inoculation in Connecticut and Kansas, while no tubercles have been found on this plant when grown in California, Florida, Iowa, Michigan, or South Dakota. The other States reporting have either not grown soy beans or have made no examination of their roots.

Concerning Alinit (*Nature*, 57 (1898), No. 1479, p. 418).—A note is given of this new substance prepared by Frederick Bayer & Co. It is claimed that it will have a beneficial effect on the growth of cereals, as in the case of Nitragin for leguminous crops. Alinit is a creamy yellow powder containing 2.5 per cent of nitrogenous constituents. It is the result of four years' laboratory experiments with different forms of bacteria, and the discoverer, M. Caron, claims that the specific organism used is a pure culture of *Bacillus ellenbachensis alpha*. The bacillus, in the form of spores, is contained in the powder and belongs to the well-known aerobic bacteria designated as the hay bacilli, resembling very closely *B. mycoides* and *B. megatherium*. It is claimed that when used as a fertilizer for cereal crops by the rapid growth of the micro-organism in the soil the combined nitrogen is made more available for the plant and that some of the atmospheric nitrogen is also secured. Further experiments will be necessary to determine the value of this substance.

The ash of epiphytes, R. C. KEDZIE (*Proc. Soc. Prom. Agr. Sci.*, 1897, pp. 71-76).—In a previous paper entitled "The chemical tripod in floriculture" the author stated that all plants in order to live and grow must receive nitrogen, phosphorus, and potash. Soon after the publication of this paper his attention was called by correspondents to the question of the presence of these substances, especially potash and phosphorus, in epiphytic plants. Analyses of a number of plants were made, in which it was found that these epiphytes were not deficient in potash or phosphoric acid. The author believes that the plants secure their mineral constituents from the water, the winds, and the bark of trees. The statement is made that in ordinary culture many of the orchids, like the cattleyas, degenerate and die within a few years. The author thinks that this is due to the lack of mineral fertilizers and sug-

gests that possibly it could be avoided by giving the plants a weak solution of phosphate of potash. He quotes articles in which similar recommendations have been made elsewhere.

Report of the botanist, C. F. WHEELER (*Michigan Sta. Rpt. 1896, pp. 133-135*).—The author gives a brief summary of the work carried on during the year, the lines of investigation being seed testing, plant diseases, herbarium work, and weed studies. Among the new weeds are reported the bladder ketmia (*Hibiscus trionnum*), winged pigweed (*Cycloloma platyphylla*), and tumbling mustard (*Sisymbrium altissimum*). Of these the latter two are liable to prove troublesome.

Report of the department of botany and forestry, W. J. BEAL (*Michigan State Bd. Agr. Rpt. 1896, pp. 501, 502*).—A tabular statement is given showing additions to the herbarium and museum during the past year.

Action of electricity on plants, TOLOMEI (*Atti R. Acad. Lincei*, 5. ser., 7 (1898), No. 6, pp. 177-183).

The action of X-rays on the living plant cell, G. LOPRIORE (*Nuova Rassegna*, 1897; abs. in *Bot. Zentbl.*, 73 (1898), No. 12, pp. 451, 452).—The author is said to have subjected *Vallisneria spiralis* for half an hour to the action of X-rays. The protoplasmic streaming was hastened. Longer exposure checked it. The action was also noted on the pollen tubes of *Genista* and *Darlingtonia coronillaefolia*.

FERMENTATION—BACTERIOLOGY.

The unorganized ferments, or enzymes, concerned in the brewing and distilling industries, I. O'SULLIVAN (*Jour. Soc. Chem. Ind.*, 16 (1897), No. 12, pp. 977-979).—The author describes the enzymes concerned in the preparation of malt and in the fermentation of brewers' wort. These are diastase of translocation, which does not erode starch granules or liquefy starch paste, but dissolves "soluble starch;" cytase, a cyto-hydrolyst, which dissolves cellular matter and is rendered inactive on heating (it is not present to any extent, therefore, in kiln-dried malt); and diastase of secretion, an amylo-hydrolyst, which liquefies and hydrolyses starch paste at all temperatures up to 80°. Analytically it is shown that they contain nitrogen and are not albuminoids. The difficulty of proving their purity without altering the properties upon which their designation depends forces the conclusion that we do not know with certainty the composition of these important products of life.—J. P. STREET.

Red yeasts, KATHERINE E. GOLDEN and C. E. FERRIS (*Bot. Gaz.*, 25 (1898), No. 1, pp. 39-46, pls. 2).—The authors describe three red yeasts which were obtained from the air of the laboratory and are designated by the numbers 1, 2, and 3. The growth of the different organisms on different media is fully described, and they are compared with the two well-known species of red yeasts, *Saccharomyces rosaceus* and *S. glutinis*. Of the three forms studied not one proved to be a true *Saccharomyces*, although No. 2 in all probability will prove to be *S. glutinis*. No. 1 appears to be a form between *Saccharomyces* and *Torula*. It forms spore-like bodies under ordinary conditions for spore formation, but as they neither form the spore wall nor bud in germinat-

ing they are not to be considered true spores. The authors believe that this is an undescribed species. No. 3, which from its peculiar appearance is easily recognized, is thought to be a new species of *Mycooderma*.

Insects and yeasts, I. GIGLIOLI (*Nature*, 56 (1897), No. 1459, pp. 575-577, figs. 3).—This briefly notes the results of experiments performed at the Portici Laboratory for Agricultural Chemistry to bring out the relations of insects, ants, flies, etc., to the invasion of fruits by yeast. As the yeast plants pass unaffected through the intestine of the fly and even multiply greatly in it, flies are very important factors in the transmission of alcoholic ferments.

subcutaneous tumefaciens, *Mycoderma cerevisia*, and *M. vini*, describing their nuclei and the changes which they undergo.

Yeast and alcoholic fermentation, J. R. GREEN (*Nature*, 57 (1898), No. 1486, pp. 591-594).—The author summarizes the present information relating to these subjects.

METEOROLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review*, 26 (1898), Nos. 1, pp. 1-43, charts 13; 2, pp. 45-89, charts 10; 3, pp. 91-137, charts 13).—Besides the usual summaries No. 1 contains an article on The tornado of January 12 at Fort Smith, Arkansas, by J. J. O'Donnell; and notes by the editor on mountain storms, Dr. Waltemath's moon, thunderstorms in California, snow rollers, and bright meteors.

No. 2 contains a special article on The search light for weather signals, by E. B. Calvert; and notes by the editor on civil-service examinations, promotion for merit, an American meteorological society, the semaquir, peculiar mountain storms, lunar rainbow, waterspout, photographs of meteorological phenomena, Greenwich noon, and whirling alto-cumulus clouds.

No. 3 contains special articles on Cumulus clouds over a fire, by R. DeC. Ward; Thunderstorms in New Brunswick, by S. W. Kain; Upper clouds and weather changes, by G. W. Richards; Normal annual sunshine and snowfall, by A. J. Henry; and The moon and the aurora, by H. A. Hazen; and notes by the editor on chinooks *vs.* the Kuro Siro, sulphur rains, moonshine and frost, and rain in the Hawaiian Islands.

Arizona weather and climate, E. M. BOGGS and N. H. BARNES (*Arizona Sta. Bul.* 27, pp. 16-65).—This is a revised edition of Bulletin 20 of the station (E. S. R., 8, p. 753). The additional data given in this bulletin relates principally to temperature.

Meteorological observations at Michigan Agricultural Experiment Station, 1895, R. C. KEDZIE (*Michigan Sta. Rpt.* 1896, pp. 443-469).—Tabulated daily and monthly summaries are given of observations during 1895 on hours of sunshine, temperature, atmospheric pressure, precipitation, humidity, wind movement, etc.

The summary for the year is as follows: Maximum temperature, 100° F., July 6, 7; minimum, -24°, February 4, December 12; mean, 46.67°; humidity, 80.05 per cent; atmospheric pressure (reduced to 32° F.), 29.077 in.; cloudiness, 51.04 per cent; amount of rain or melted snow, 22.8 in.; snowfall, 49.14 in.; number of thunderstorms, 13.

The rainfall tables of the British Islands, 1866-1890 (*Met. Council [Great Britain], Offic. Doc. 114, pp. 253, maps 3.* London: Eyre & Spottiswoode, 1897).—Tables give summaries of observations during this period at 492 stations, distributed as follows: 287 in England and Wales, 151 in Scotland, and 54 in Ireland. The maps show the main watersheds and catchment basins of the principal rivers. These tables include data contained in similar tables published in 1883, which covered the period from 1866 to 1880, with the addition of the rainfall records from 1880 to 1890.

Future rainfall, A. B. M. (*Nature*, 58 (1898), No. 1489, pp. 30, 31, chart 1).—By charting the series obtained by "algebraic addition, step by step, of a series of plus and minus values," it is shown that there is a regular recurrence in Great Britain at intervals of about thirty-five years of cold and wet periods. This bears out the statement of Brückner that such periodicity occurs in various parts of the world.

Investigations on the relation of atmospheric precipitation to plants and soils, E. WOLLNY (*Forsch. Agr. Phys.* [Wollny], 20 (1898), No. 3, pp. 346-360).—This is a general discussion of the influence of an excess or deficiency of water, injurious effects of water on the mechanical properties of soils, the leaching of soils, the accumulation of soluble salts in the soil, and the influence of snow, hail, etc.

Forecasts of frosts, R. C. KEDZIE (*Michigan Sta. Spec. Bul.* 5, pp. 10).—A popular discussion of means of forecasting frosts and protecting plants from injury. Among the means of protection suggested are irrigation and smudges.

On a new form of constant volume air thermometer, which shows the total pressure directly, and may be graduated in degrees of temperature, J. R. E. MURRAY (*Proc. Roy. Soc. Edinburgh*, 21 (1895-1897), pp. 299-302, figs. 2).

Exploration of the air by means of kites (*Cambridge*, 189-, pls. 3, pp. 43-128, pls. 7; reprinted from *Ann. Astron. Observ. Harvard College*, 42 (1897), 1).

Forestry-meteorological studies, E. HOPPE (*Centbl. Gesam. Forstw. Wien*, 24 (1898), No. 3, pp. 99-126).

On measures for the amelioration of the climate, H. STEINMETZ (*Ber. Andra Nord. Landtbr. Kongr., Stockholm*, 1897, I, pp. 110-139, ill. and charts).—Treats of the frost phenomenon, drainage systems, and the forest problem.

The influence of the movements of the moon on the oscillations of the atmosphere, P. GARRIGOU-LAGRANGE (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 16, pp. 1173-1176).

Influence of diffused solar light on the growth of plants, J. WIESNER (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 18, pp. 1287-1289).

Monthly reports of the River and Flood Service, W. L. MOORE and P. MORRILL (*U. S. Dept. Agr., Weather Bureau Docs.* 153, pp. 18, chart 1: 156, pp. 14, chart 1: 158, pp. 19, chart 1).—Résumés of observations on river stages and conditions of navigation during the months of January, February, and March, 1898.

Wrecks and casualties on the Great Lakes during 1895, 1896, and 1897, W. L. MOORE and N. B. CONGER (*U. S. Dept. Agr., Weather Bureau Doc.* 159, pp. 23, charts 3).—A chronological record.

WATER—SOILS.

The Beeville Station: Soils, climate, water supply, and irrigation equipment, J. H. CONNELL and S. A. MCHENRY (*Texas Sta. Bul.* 43, pp. 929-958, pls. 1, figs. 11).—This is the first report of the experiment station in this part of southern Texas provided for by State appropriation.

Soils.—The region presents a gently rolling surface, which is largely devoid of forest growth, except along the water courses. The open prairie is covered with mesquite grass.

“The surface of the soil is a dark brown sandy loam, which lies over a whitish marl, carrying a large percentage of lime. This dark surface soil in some cases shades into a chocolate red, or turns to a sandy white on some of the hillsides. In the valleys it is almost black, because of the large amount of decayed vegetable matter contained, and in such situations it is usually heavy and obstinate under the plow, and the surface soil is several feet in depth, while on the slopes and tops of hills it varies from 6 to 18 in. in depth.”

The soils of this region are located on the Fayette beds, and for the purpose of investigation were divided into three main groups: (1) Vegetable soils, (2) orchard soils, and (3) field crop soils. Samples of these soils were taken at three different depths, 1 to 6 in., 24 to 30 in.,

and 48 to 54 in., and analyzed. The results of analysis are given in the following table:

Analyses of Beerille soils.

	Vegetable soil.			Orchard soil.			Field crop soil.		
	1-6 in.	24-30 in.	48-54 in.	1-6 in.	24-30 in.	48-54 in.	1-6 in.	24-30 in.	48-54 in.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Silica and sand.....	87.92	67.9	19.82	89.06	80.2	18.99	89.74	62.88	29.21
Organic matter.....	4.36	4.79	1.63	3.70	4.38	2.36	4.87	5.12	3.42
Water.....	1.55	2.55	.92	2.07	4.25	.62	2.50	3.30	1.05
Oxids of iron and alumina.....	4.57	7.08	2.86	3.65	10.13	2.95	.95	6.33	1.49
Calcium oxid.....	.76	10.21	43.19	.67	.72	39.93	.60	9.04	35.37
Magnesium oxid.....	.47	.63	.65	.41	.31	.94	.13	.51	.39
Sulphuric acid.....	.09	.10	.19	.05	.04	.24	.08	.10	.10
Potassium oxid.....	.32	.24	.11	Trace.	Trace.	.16	Trace.	Trace.	Trace.
Sodium oxid.....	.13	.16	.25	.75	.37	.21	.86	.69	.62
Carbon dioxide.....	.58	.67	29.56	32.8	1.14	12.05	28.40
Phosphoric acid.....	.04	.03	.04	.01	.13	.04	.06	.04	.01

The conditions which tend to cause a rapid destruction of the organic matter in these soils are discussed and the means of preventing this loss are explained, the use of velvet beans as a green manure being especially recommended. The presence of sulphur and gypsum in the geological formation from which the soils are derived probably partly explains the rapid destruction of the organic matter.

Climate and rainfall.—Data for rainfall, temperature, cloudiness, and direction of the wind for each month from January, 1896, to August, 1897, are tabulated, and a chart shows the average annual precipitation in different regions of Texas. The maximum temperature recorded (104°) occurred in July and August, 1897; the minimum temperature (19°) occurred in January, 1897.

Agricultural water supply.—After general remarks on soil water, absorptive power of soils, and effect of subsoiling, the underground water supply of this region is discussed. It is stated that the region is underlaid at a depth of from 50 to 150 ft. by “a coarse water-bearing sand that supplies an abundant flow of good water in dug or bored wells at all times. This water rises to within 30 ft. of the surface in some cases, and can be economically raised for irrigation purposes and is largely used for domestic consumption. Windmills are in general use, but thus far we have been unable to learn of the successful use of mills for irrigating crops of more than 1 or 2 acres in each case.”

The flow of these wells is, however, decreased to a marked extent by long-continued drought, the lowest point probably being reached during the months of September and October.

“The well on the station grounds is dug to a depth of 57 ft., and a 4-inch hole bored from this point to a depth of 74 ft. The water usually stands 8 ft. deep in the dug portion of the well, or a distance of 49 ft. from the surface of the ground. While using a windmill for driving the pump, the water fell some 20 ft. in this well, and when pumping with a gasoline engine we exhausted the water to a point as far down as was reached by the deep-well cylinder, but on forty strokes per minute (in April, 1897), this pump, on a 15-inch stroke, was run to lift 1,000 gal. of water per hour for twelve hours, and in removing these 12,000 gal. the water in the well was lowered, but not exhausted.

“In September, 1897, a careful test was made of the available supply in this well. The pump was placed on a 24-inch stroke and was run at the rate of forty-four strokes per minute. At this rate the well supplied 24 gal. per minute delivered at the reservoir (equal to 1,440 gal. per hour), but this fast pumping partially exhausted the supply of water in the well, after which a flow of 13 gal. per minute was obtained. This, we concluded, was the normal force of the stream supplying the well after some months of drought and very low average rainfall throughout the section to the north and west supposed to supply this sheet water that flows at a depth of 75 to 90 ft. below Bee County. During the preceding spring season the supply had been materially stronger.”

To the north of Beeville and along the coast flowing wells are obtained by tapping this water-bearing stratum.

Irrigation.—The need of irrigation in the region of Texas in which Beeville is situated and the duty of water are discussed and the pumping outfit at the station is described. This consists of “a windmill and gasoline engine, so arranged as to use either wind or explosive gas as power for driving the pump, and is situated in a depression, or ‘draw.’ The reservoir is located on the rise of the hill and is 560 ft. east of the well and pump station. The top of the reservoir is some 15 ft. above the ground level of well. Water must be pumped from its level to surface of well (49 to 70 ft.) plus the ‘rise’ from well to discharge pipe in reservoir (15 ft.). This provides for a total pump lift of 64 to 85 ft. When pump is used regularly and water is lowered in well the lift is probably about 80 ft.”

At the beginning a 12-foot steel windmill was relied on entirely to pump the water required, but “in many cases the windmill failed to show sufficient strength to run the pump for days at a time. In such cases the experimental crops would suffer severely from droughts.”

“An existing popular idea to the effect that windmills can be relied upon to lift irrigation water from depths of 75 to 100 ft. must be critically examined by those intending to use mills for this purpose. All semiarid sections are supposed to have frequent and strong winds, but for windmill irrigation purposes they must also be regular, or, just at the critical crop-growing period, a calm may occur and entirely ruin the prospects of the farmer or trucker, and so cause the loss of labor and capital invested for that season. The regularity with which the wind blows, the depth from which water must be pumped, and the size of the receiving reservoir are the factors that determine the success of windmill irrigation plants.”

In the spring of 1897 a 4-horsepower gasoline engine with pumping apparatus was installed, and it has been used with very satisfactory results. With this plant the cost of raising 1,000 gal. of water 65 to 85 ft. through 560 ft. of 2½-inch pipe has been found to be 8.42 cts., or at the rate of \$4.58 per acre (2 acre-inches).

The construction of reservoirs is discussed and directions are given for the construction of dams with concrete, masonry, and puddle cores and with surfaces of coal-tar mastic and concrete gravel.

Statements regarding methods of distributing and applying irrigation water are reprinted from the Yearbook for 1895 of this Department, and the influence of irrigation water on the increase and rise of alkali in soils is briefly discussed.

Investigations on the influence of the physical properties of soils on the growth of crops, E. WOLLNY (*Forsch. Agr. Phys.* [Wollny], 20 (1898), No. 3, pp. 291-311).—This is a detailed account of experiments during several years with a large variety of crops grown in boxes and pots. The special subjects investigated and reported on in this article are inclination and exposure of the surface of the soil, depth of the cultivated soil layer, fineness of the soil particles, color of the soil, and character of the soil.

With normal weather conditions and sufficient moisture the greatest yield was obtained on soils having a southerly exposure and the greater inclination (not over 30°). Plants also started growth earlier in the spring on the soils with the greater inclinations. In dry weather, however, the opposite results were obtained.

There did not appear to be any direct and uniform relation between the depth of the soil and the growth of the plants.

Within the limits experimented with (less than 0.25 to 2 mm.) the smaller the soil particles the greater the yield.

Plants germinated more quickly and uniformly and produced larger crops in dark-colored soils than in light-colored soils.

With approximately the same chemical composition the highest yields were obtained from humus soils; the lowest from sandy soils.

The experiments show in general that the influence of the physical properties of soils on their productive capacity is of the highest importance and that fertilizers exert a most marked influence upon the physical properties of soils.

Relative sensitiveness of plants to acidity in soils, W. MAXWELL (*Jour. Amer. Chem. Soc.*, 20 (1898), No. 2, pp. 103-107).—The methods followed in the study of this subject are thus described:

“Two tubs having a diameter of 24 in. and a depth of 20 in. and perforated bottoms, which were covered with linen cloth, were each filled with 120 lbs. of air-dried soil of moderate fertility, having a neutral behavior toward acid and alkaline tests. These tubs were placed in tin pans which were 6 in. deep, the perforated bottoms of the tubs being raised 4 in. above the bottoms of the tin pans. The tin pans were filled with water up to the level of the perforated bottoms, and the water was kept up to that level until the soil in the tubs had absorbed moisture to saturation, the water absorbed being 48.2 per cent on the water-free weight of the soil. To tub No. 1 enough citric acid was added to make the whole volume of water absorbed a one-tenth per cent solution. To tub No. 2 citric acid was added to make the absorbed water a one-fiftieth per cent solution. In each of the tubs 17 varieties of seeds were planted, these being planted in a circle and equal distances apart. The seeds germinated quickly, were up within four days, and had a healthy appearance. After the plants were up and 1 in. high the mode of applying the acid was changed. When the acid was applied in the water absorbed by capillarity from the tin pans it was not equally distributed through the mass of the soil, but was more or less fixed by the bases in the soil at the bottom of the tubs, and did not reach the plants. Therefore the acid was dissolved in water and applied around the plants at the surface. This was controlled by determining the loss of water from the tubs by evaporation and replacing the lost water, with the weight of citric acid dissolved in it necessary to bring up the whole volume of water in the tubs to one-tenth per cent and one-fiftieth per cent solutions, respectively. This was repeated every fourth day.”

The plants experimented with were black and white mustard, beets, mangel-wurzels, rape, carrots, white lupines, common bean, Windsor bean, winter vetch, crimson clover, alfalfa, pearl millet, wheat, maize, oats, and barley. The results show that all the cruciferous plants and clovers succumbed at once to the acid. Although certain of the leguminous plants and Gramineæ made considerable growth, only pearl millet reached normal development. "Its growth was steady and quite normal as compared with a plat of millet growing in a field near by, which it actually exceeded in development."

Soil humus, E. F. LADD (*North Dakota Sta. Bul. 32, pp. 272-276*).—A brief explanation is given of "what is meant by the term soil humus and in what way its presence in the soil is beneficial." based in part upon results of the author's own investigations and in part on results obtained at other stations. "The average of fifty-four determinations gave 13.79 per cent of organic matter for North Dakota soils and 4.55 per cent of humus." In eight analyses of North Dakota soils 41 per cent of the phosphates was found in the humus, the proportion ranging from 10 to 91 per cent. From 46 to 80 per cent of the total nitrogen was found in the humus, the average proportion being 61 per cent.

The objects and methods of soil analysis, E. W. HILGARD (*Proc. Soc. Prom. Agr. Sci., 1897, pp. 20-25*).—This is a plea for the complete analysis (at least for the determination of lime, magnesia, iron, and soluble silica in addition to nitrogen, phosphoric acid, and potash) of the strong acid solution of soils. It is claimed that analysis must not only show whether "nitrogen, phosphoric acid, or potash are deficient or abundant, but it must also show what, from the general character of the soil, is the form in which these substances should be applied, and in what manner." This information can be obtained only by the determination of other constituents besides nitrogen, phosphoric acid, and potash.

It is questioned whether the sulphuric-acid method proposed by Goss has any advantages over the nitric-acid method heretofore practiced. The use of dilute hydrochloric acid for determining available potash and phosphoric acid in soils, as proposed by Goss, is believed to be a promising method.

"The remarkable effect of calcium chlorid, however, causes me to suggest that the effect of neutralization would, in the case of HCl, be quite different from that of citric acid, so far as potash is concerned; for in many cases the amount of calcium chlorid formed by neutralization will greatly exceed in its effects that of the HCl itself, and it would therefore seem that as a general reagent for the determination of available potash the latter is unavailable for the great majority of soils."

Drinking waters, E. F. LADD (*North Dakota Sta. Bul. 32, pp. 267-270*).—The total solids and sodium chlorid in twenty samples of artesian water and complete mineral analyses of three of the samples are reported, with notes on the interpretation of results of water analyses.

The underground waters of the Arkansas Valley in eastern Colorado, G. K. GILBERT (*U. S. Geol. Survey Rpt. 17, pt. 2, pp. 551-601; abs. in Tech. Quart., 11 (1898), No. 1, Rev. Chem., p. 23*).

Preliminary report on artesian waters of a portion of the Dakotas, N. H. BARTON (*U. S. Geol. Survey Rpt. 17, pt. 2, pp. 603-655; abs. in Tech. Quart., 11 (1898), No. 1, Rev. Chem., pp. 23, 24*).

The water resources of Illinois, F. LEVERETT (*U. S. Geol. Survey Rpt. 17, pt. 2, pp. 655-828; abs. in Tech. Quart., 11 (1898), No. 1, Rev. Chem., p. 24*).

Temperatures of different soils, D. J. CROSBY (*Michigan Sta. Rpt. 1896, pp. 198-200*).—A reprint from Bulletin 125 of the station (*E. S. R., 7, p. 374*).

Soil temperature observations at the observatory of Catania, 1892-1896. E. TRINGALI (*Atti Accad. Gioenia Sci. Nat.; abs. in Nature, 58 (1898), No. 1489, p. 40*).—“In addition to confirming the well-known laws according to which the diurnal and annual variations of temperature decrease and undergo retardation with increasing depth,” the results of these observations “show that at Catania the velocity of transmission of the diurnal fluctuations is about 20 cm. for every $7\frac{1}{2}$ hours, and that these fluctuations become practically unimportant at a depth of 60 cm., where they only amount to a few tenths of a degree when the atmospheric temperature changes as much as 17 degrees.”

Researches on the composition of the soil of Crau and of the soils and clays of Durance, G. CASTIN (*Ann. Sci. Agron., 1898, 1, Nos. 1, pp. 155-160; 2, pp. 161-239*).—Analyses of typical soils of this region with notes on their characteristics.

Examination of marsh soil samples, G. E. STANGELAND (*Tidsskr. Norske Landbr., 5 (1898), pp. 180-182*).

Forests and subterranean waters in level regions, E. HENRY (*Ann. Sci. Agron., 1898, 1, No. 1, pp. 1-24*).

Iowa Geological Survey. VI, Report on lead, zinc, artesian wells, etc. (*Des Moines: Iowa Geological Survey, 1897*).—Contains, among others, papers on artesian wells and relation of Wisconsin and Kansas drifts in central Illinois.

FERTILIZERS.

The fertilizer industry, J. HYDE and G. K. HOLMES (*U. S. Dept. Agr., Division of Statistics Bul. 13, pp. 27*).—This bulletin contains statistics of production and consumption of fertilizers in the United States; a preliminary report on a statistical study of the relation between the fertilizers applied and the profit obtained in cotton growing; and notes on fertilizer inspection, with abstracts of the different State fertilizer laws and a list of fertilizer inspection officials.

It is estimated that the total number of establishments in the United States that manufacture fertilizers is about 700. In 1880 the census reported 364; in 1890, 390. “Since 1890 there has been a very considerable development in the manufacture of fertilizers, especially in South Carolina and Florida, where phosphate mining has assumed large proportions.”

It is stated that attempts to collect statistics of the production of fertilizers have been unsuccessful. “With respect to consumption, however, the case is different, and it has been possible, with the aid of State fertilizer inspectors and other State officials, to ascertain approximately the quantity and value of the commercial fertilizers consumed in the United States in the calendar year 1896.” More or less complete data are also given for the period from 1891-1895, and for the first nine months of 1897.

The data for 1896 and up to October 1, 1897, are given in the following table:

Commercial fertilizers consumed in the United States in 1896 and up to October 1, 1897.

State.	1896.		To October 1, 1897.	
	Amount.	Value.	Amount.	Value.
	<i>Tons.</i>		<i>Tons.</i>	
Vermont.....	13, 000	\$401, 700		
Connecticut.....	20, 000	600, 000	14, 000	\$408, 660

¹Purchases for farm use as reported in census of 1890, at average value for 1896.

Statistics of production and consumption of fertilizers are republished from the Tenth and Eleventh Censuses and from reports of the U. S. Department of Labor and of the Geological Survey, and a statement of imports and exports of fertilizing materials is quoted from reports of the Bureau of Statistics of the U. S. Treasury Department.

Returns from 1,495 cotton planters, giving "the cost of fertilizers used in raising cotton in 1896 on an average acre under cotton cultivation" besides "other items of expense and the income received from the cotton and seed," are stated in tabular form, those who made a profit being separated from those who suffered a loss and each class tabulated according to the amount expended for fertilizers.

"It appears that there were 21 planters who spent less than \$1 each per acre for fertilizers, and that their average profit was \$4.62 per acre. The planters who spent from \$1 to \$1.99 per acre for fertilizers had an average profit of \$5.09 per acre; those who spent from \$2 to \$2.99 had an average profit of \$5.34; those who spent from \$3 to \$3.99 had an average profit of \$5.91; those who spent from \$4 to \$4.99 had an average profit of \$7.96; those who spent from \$5 to \$5.99 had an average profit of \$8.76; while the planters whose fertilizers cost them per acre \$6 and over, had an average net profit per acre of \$12.51.

"It will thus be noticed that increase of expense for fertilizer in cotton raising apparently leads to increase of profit, and further, that, as far as this table discloses, the point of diminishing returns was not reached in the total for the five States that are included, and where it was reached, apparently, in any State, the result is probably a chance one due to the small number of returns."

Investigations on manure at Lauchstädt, 1896-1897, M. MAERCKER and W. SCHEIDEWIND (*Landw. Jahrb.*, 27 (1898), No. 1-2, pp. 215-240, pls. 3).—These include (1) studies of the loss of nitrogen from manure in deep stalls and in open and covered manure heaps, and (2) experiments with preservatives.

Three experiments with deep-stall manure are reported, two with manure from cattle and one with manure from sheep. The first experiment with cattle was made with 12 animals and lasted for 136 days (June 16 to October 29, 1896). In the second experiment 14 steers were used and the experiment lasted from November 6, 1896, to May 21, 1897 (197 days). The experiment with sheep was made with four lots of 15 animals each and lasted from June 20, 1896, to January 14, 1897. The stalls used in these experiments were 0.65 meter deep and had impervious cement bottoms.

Parallel with the experiments on deep-stall manure under cattle, studies were made of the losses of nitrogen from open and covered heaps of manure from animals fed the same kinds and amounts of food and supplied with the same amount of litter as in the deep-stall experiments. Samples of manure for analysis were taken daily. Not only the total nitrogen, but also the albuminoid, amid, ammoniacal, and nitric nitrogen were determined.

In the experiments with preservatives the manure from 9 cows during a period of 11 days was divided each day into four lots which were sampled for analysis and packed separately in pits. Lot 1 received no preservative; lot 2 received 30 per cent of marl containing 13 per cent of carbonate of lime; lot 3, 30 per cent of marl and 2 per cent of peat; lot 4, 6 per cent of sodium bisulphate, corresponding to 1.5 per cent of free sulphuric acid. The total albuminoid, amid, ammoniacal, and nitric nitrogen in the fresh manure and in the manure after remaining in the pits three months were determined.

The results of the experiments show that the loss of nitrogen in deep stalls was small when the manure was examined immediately after the animals were removed from the stalls, being in one case 13.2 per cent and in another 13.25 per cent of the total nitrogen. This was true whether the experiments were conducted in winter or in summer. The loss, however, increased to 34.8 per cent when the manure was allowed to remain four weeks during warm weather after the animals had been removed from the stalls. If the manure, therefore, can not be carried to the field immediately after the removal of the animals it should be covered with soil or treated with a preservative.

In an ordinary uncovered manure heap the loss of nitrogen was 37.4 per cent. In a covered heap it was very little less, being 36.9 per cent. This slight difference in the loss in the two cases is thought to have been due to the fact that the weather conditions were especially favorable to the preservation of manure in the uncovered heap, being wet and cloudy, while the manure in the covered heap was allowed to

become too dry. That decomposition was more rapid in the covered heap than in the uncovered heap is shown by the fact that the loss of organic matter was 30 per cent in the former and only 22 per cent in the latter. This shows the importance, especially in case of covered manure heaps, of keeping the manure moist and well compacted.

In case of the covered and uncovered heaps the liquid manure was allowed to drain off and was collected in separate receptacles. Under these conditions there was almost a total loss of the nitrogen in the liquid, the amount falling from 0.2–0.3 per cent to 0.01–0.05 per cent.

It appears that during the decomposition which goes on in the manure heap considerable amounts of nitrogen in the simpler forms are converted into albuminoid and similar complex compounds, this change being greater in case of deep-stall manure than in that from ordinary stalls. By adding an excess of 0.5 per cent of sulphuric acid to the manure which had remained in the deep stalls 136 days the amount of albuminoid nitrogen was reduced from 65.1 per cent to 47.5 per cent of the total nitrogen, ammoniacal and amid nitrogen being correspondingly increased.

The addition of 30 per cent of marl to the manure reduced the loss of nitrogen from 22.6 to 9.9 per cent, and the addition of 30 per cent of marl and 2 per cent of peat reduced the loss to 6.1 per cent. The best results, however, were obtained by adding 6 per cent of sodium bisulphate, corresponding to 1.5 per cent of sulphuric acid, which reduced the loss to 1.3 per cent. The manure treated with sodium bisulphate remained practically unchanged.

On the losses of ammonia which take place in the preparation of barnyard manure, P. P. DEHÉRAIN (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 19, pp. 1305–1310).—This is a brief account of laboratory experiments with ammonium carbonate, urine, and urine and straw, undertaken for the purpose of explaining the losses of nitrogen from manure. A solution of ammonium carbonate lost 73 per cent of its nitrogen in 30 days in the open air. In a closed flask in which was suspended a dilute solution of sulphuric acid to absorb ammonia 12.1 per cent of the nitrogen passed off from a solution of ammonium carbonate in 3 days and 24.2 per cent in 8 days. In closed flasks provided with sulphuric acid to absorb ammonia and sodium hydrate to absorb carbon dioxid 39.3 per cent of the nitrogen escaped in 3 days and 83 per cent in 8 days. In an atmosphere charged with carbon dioxid the escape of ammonia was very slight. Urine exposed to the air lost 45 per cent of its nitrogen in one month. In a closed flask the loss in the same time was only from 5.6 to 6.6 per cent. In flasks provided with sulphuric acid for absorbing the ammonia 21 per cent of the nitrogen of the urine escaped in 5 days, but at the end of that time none of the ammonia formed had been absorbed by the sulphuric acid. At the end of 11 days, however, 19 per cent of the nitrogen of the urine was found in the sulphuric acid. When provision was made for absorption of

both ammonia and carbon dioxide in a closed flask there was a loss of only 2.9 per cent of nitrogen in 5 days, but 52 per cent in 11 days. In experiments in which 4 parts of urine were mixed with 1 part of straw (an insufficient amount to absorb all the urine) and exposed to the air during the summer (June, 1897), 58.3 per cent of the nitrogen escaped in 2 days, 70 per cent in 4 days, 72.6 per cent in 6 days, and 75.7 per cent in 8 days. These figures serve to indicate the great losses which may occur when insufficient amounts of litter are used.

In experiments in which litter was used in larger quantities, 1 part of litter to 2 of urine, the losses of nitrogen in the open air were only 7.2 per cent in 8 days. In closed flasks in which arrangements were made for the absorption of the ammonia and carbon dioxide 7.9 per cent of the nitrogen escaped in 3 days, 31.5 per cent in 6 days, 52.6 per cent in 8 days, and 59.7 per cent in 12 days. In an atmosphere of carbon dioxide no nitrogen escaped from the mixture, although the larger part of the nitrogen present was converted into ammonia. This is the condition in a well-constructed and compacted manure heap.

Potash: Its commercial and agricultural relations and a chemical method for its accurate estimation in soil, A. T. NEALE, W. H. BISHOP and C. L. PENNY (*Delaware Sta. Bul. 36, pp. 24, figs. 3*).—The economy of using potash fertilizers is discussed and it is shown that in spite of “a decline in values of all farm products and in spite of a decline of 65 per cent in the phosphate market the muriate of potash has been held for fifteen years unchanged in quality and in price.” In view of this fact it is recommended that those systems of farming be practiced which utilize the latent potash of the soil. For this purpose the old-fashioned combination of lime and clover is considered especially valuable. It is suggested that from 7½ to 10 bu. of stone lime per acre applied with an ordinary grain drill with fertilizer attachment will be found as effective in many cases as the heavier applications which have been hitherto applied.

The results of an experiment with different fertilizer mixtures during 1894–1897 on sweet corn, crimson clover, cowpeas, oats, and red clover are reported. Muriate of potash gave noticeably good results on sweet corn and red clover, and the mixture of muriate of potash and acid phosphate was especially effective on cowpeas.

Potash was determined in the first and second foot of the soil of these plats by the following method: Samples of soil were ignited to dull redness and pulverized until they would pass a sieve of 80 meshes to the inch. Five hundred grams of this pulverized soil was placed in a 2-liter Jena glass flask with 1 liter of 20.7 per cent hydrochloric acid, and heated by means of steam to 100° in a rotary apparatus for 7 hours. The apparatus used for this purpose is described and figured. The acid solution obtained was filtered without washing, and a portion of the filtrate was taken for further operation. The amount so used was found by calculations based on the chlorine content of the acid solution. The method of calculation is fully explained.

The acid solution taken for analysis was evaporated to dryness in a liter Jena flask, using an air blast to hasten evaporation. The special apparatus used for this purpose is described and illustrated. The dried residue was taken up with water and boiled until all the normal salts were dissolved and the basic precipitate was in the form of a fine powder. All the bases present which formed insoluble carbonates or hydroxids were precipitated by adding freshly prepared silver carbonate until all chlorine was precipitated.

A second partition similar to the one just described was effected at this point by weighing the solution with the insoluble precipitate and, after drying the latter at a gentle heat, deducting its weight. The filtrate from this precipitate contains potash and soda, a trace of magnesia, some lime as bicarbonate, a little manganese, and some silver carbonate, and is alkaline in reaction. It was evaporated to dryness, which separated the silver, manganese, and lime. The filtrate from this residue was acidified with hydrochloric acid, and the potash determined in the usual way. In all cases evaporation was hastened by the use of the air blast.

The method "is designed for investigations important enough to justify the expense. The cost of so slow and tedious processes would be prohibitive for transient commercial purposes."

The results of the determinations of potash in the soils of the different plats showed no variations which could be traced to the different systems of fertilizing employed.

Inoculation of soil with ferments, P. P. DEHÉRAIN (*Ann. Agron.*, 24 (1898), No. 4, pp. 174-180).—This is a general discussion of the subject under the following heads: The introduction of ferments into the soil—Nitragin, alinite, and nitrifying soils; organisms which naturally occur in the soil, and influence of medium on the activity of organisms. The necessity for investigating the conditions under which it proves profitable to inoculate soils with organisms which fix nitrogen is pointed out. It is suggested that the contradictory results obtained by different investigators may be due to insufficient knowledge as to the medium which is best suited to the growth of the different organisms.

The conservation of barnyard manure viewed from a practical standpoint, A. ARNSTADT (*Fühling's Landw. Ztg.*, 47 (1898), No. 2, p. 66).

The fertilization of the Campine, L. BAREEL (*Rev. Gén. Agron.*, 1898, Nos. 2, pp. 73-77; 4, pp. 173-177).—Green manuring, the use of night soil, and sewage irrigation are discussed, especial attention being given to the last.

Investigation on the action of sulphate of ammonia and nitrate of soda, G. KLOEPFER (*Untersuchungen über die Wirkung des schwefelsäuren Ammoniaks und des Chilisalpeters*. Essen: G. D. Baedeker, 1898).

Comparative experiments with ammoniacal and nitric nitrogen (*Deut. Landw. Presse*, 25 (1898), Nos. 25, pp. 271, 272, figs. 2; 26, pp. 284, 285, figs. 4).—This is a summary of the experiments by Kloefer, which indicated that sulphate of ammonia is more economical than nitrate of soda, especially for application to cereals in the spring.

Ammonium salts vs. nitrate of soda, P. WAGNER (*Deut. Landw. Presse*, 25 (1898), Nos. 30, p. 327, fig. 1; 31, pp. 336, 337).—Experimental data are quoted to show that the conclusions of Kloefer (see above) regarding the greater economy as a fertilizer of ammonium salts over nitrate of soda are erroneous.

Difference in action of muriate of potash and sulphate of potash (*L'Engrais*, 13 (1898), No. 13, pp. 300-302).—A popular summary of investigations on this subject.

The use of potash salts, MAIZIÈRES (*L'Engrais*, 13 (1898), No. 17, pp. 395-397).—Statistics of the production and distribution of the various Stassfurt salts, by countries, 1893-1897.

The use of salts of potash in agriculture (*L'Engrais*, 13 (1898), No. 18, pp. 420, 421).

Analyses of licensed commercial fertilizers, F. W. WOLL (*Wisconsin Sta. Bul.*, 66, pp. 7).—Analyses of five samples of fertilizing materials are reported, accompanied by notes on the terms used in stating analyses and on valuation of fertilizers.

Composition of commercial fertilizers, H. B. McDONNELL ET AL. (*Maryland Sta. Bul.*, 52, pp. 49-105, fig. 1).—Tabulated analyses and valuations of 393 samples of fertilizing materials examined during the period from August, 1897, to January, 1898; a list of fertilizers licensed for sale in Maryland for the year ending February 1, 1898; and the text of the State fertilizer law.

Commercial fertilizers, H. A. HUSTON and W. J. JONES, JR. (*Purdue University Spec. Bul.*, May, 1898, pp. 8).—General statements regarding the amount and character of fertilizers sold in Indiana during the past season, notes on valuations, and tabulated analyses and valuations of 340 samples of fertilizing materials.

Commercial fertilizers, B. H. HITE (*West Virginia Sta. Bul.*, 51, pp. 51-85).—This bulletin includes tabulated analyses and valuations of 184 samples of fertilizers examined during 1897, accompanied by notes on the nature and source of various materials supplying phosphoric acid, potash, and nitrogen; and on humus, stimulant fertilizers, home-mixing of fertilizers, valuation, and inspection of fertilizers. The text of the State fertilizer law is given.

Analyses of commercial fertilizers, B. W. KILGORE (*Mississippi Sta. Bul.*, 48, pp. 7).—Analyses and valuations of 39 samples of fertilizing materials are reported.

Fertilizers, J. H. STEWART and B. H. HITE (*West Virginia Sta. Spec. Bul.*, May 1, 1898, p. 1).—Tabulated analyses and valuations of 144 samples of fertilizers registered in West Virginia during the period from January 1 to May 1, 1898.

Inspection of commercial fertilizers, R. C. KEDZIE (*Michigan Sta. Rpt.*, 1896, pp. 209-222).—A reprint of Bulletin 126 of the station (E. S. R., 7, p. 380).

Manuring experiments, 1897 (*Jour. Agr. and Ind. South Australia*, 1 (1898), No. 9, pp. 680-687).—A report on cooperative fertilizer experiments.

Fertilizer experiments conducted at Mustiala experiment station (Finland) during 1894, A. RINDELL (*Landtbr. Styr. Meddel.*, 1897, No. 20, pp. 1-30).—Includes field trials with fertilizers for oats, examination and analyses of marsh soils, pot experiments with different phosphates, and culture trials with potatoes.

FIELD CROPS.

Some experiments in corn raising, C. D. SMITH (*Michigan Sta. Bul.*, 154, pp. 259-288, *dgms.* 2).—This bulletin gives a report of the work with the selection of seed, thickness of planting, and cultivation of corn, and on the study of the relative value of the leaves, stalks, and ears; the loss in the silo of corn cut at different stages of growth; and the stage of growth when the crop contains the largest amount of nutriment. The results are discussed and given in tables.

In 1897 two plats were planted to corn; one with seed grown in 1895,

the other with seed grown in 1896. In 1895 the corn had ripened well; in 1896 the crop was not fully as mature. The seed of 1895 produced a total yield of 19,134 lbs. per acre and the seed of 1896, 17,210 lbs. The dry matter produced per acre was 7,749 lbs. and 6,970 lbs., respectively. The difference in favor of seed of 1895 was over 11 per cent.

In 1896 five plats and in 1897 four plats were planted to corn, the thickness of planting being different for each plat. The season of 1896 was wet, while of 1897 the summer was dry. The distance of planting and the results for the two seasons are given in the following table:

Yields per acre of fodder corn on thickly sown and thinly planted plats, 1896-97.

No. of plat.	Distance of planting.	Green fodder.	Dry matter.	Protein.	Nitrogen-free extract.	Crude fiber.	Fat.
	1896.	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
1	Seed drilled in rows 7 in. apart.....	30,608	9,411.96	300.24	6,056.59	2,459.35	164.71
2	Rows 14 in., kernels 3 in. apart.....	17,008	5,483.38	188.08	3,651.93	1,295.72	110.76
3	Rows 2 ft. 4 in., krrl. 3 in. apart.....	21,860	7,590.17	588.01	5,016.11	1,359.03	269.26
4	Rows 3 ft. 9 in., hills 1 ft. 10 in., 4 kernels to a hill.....	19,344	5,814.81	389.01	3,785.44	1,208.90	185.49
5	Hills 3½ ft. by 3½ ft., 4 kernels to a hill.	16,416	4,790.19	331.96	3,115.06	922.11	170.05
	1897.						
1	Rows 7 in., kernels 3 in. apart.....	16,870	5,940.00	237.87	3,965.97	1,347.00	96.67
2	Rows 14 in., kernels 3 in. apart.....	19,724	7,454.00	394.48	4,871.83	1,600.40	156.91
3	Rows 28 in., kernels 3 in. apart.....	16,100	6,295.00				
4	Rows 42 in., kernels 3 in. apart.....	17,210	6,970.00	526.80	4,885.23	1,085.78	120.00

The results obtained at other stations are considered and the composition of the dry matter of the crops is given. For silage corn 3½ ft. between rows and from 3 to 6 in. between plants in the rows are considered favorable distances.

Cultivation tests were made on three plats. The corn was planted May 8 and was harrowed and given two cultivations prior to June 25, when the test was begun. Plat 1 was left without cultivation; plat 2 was cultivated twice per week up to July 21, and again August 6; and plat 3 was cultivated twice after June 25. On July 22 the weeds were cut from all the plats. From June 25 to the end of August 30 soil samples were taken for determining the water content, the average being given in the following table:

Water content of three corn plats.

	Plat 1, uncultivated.		Plat 2, cultivated twice a week.		Plat 3, ordinary cultivation.	
	Per cent.	Amount per cubic foot.	Per cent.	Amount per cubic foot.	Per cent.	Amount per cubic foot.
First foot.....	12.70	<i>Pounds.</i> 11.18	14.91	<i>Pounds.</i> 13.12	14.79	13.02
Second foot.....	12.55	12.30	12.99	12.73	12.22	11.97
Third foot.....	14.51	14.22	14.86	14.56	15.18	14.87

The relative development of ears, stalks, and leaves was studied in 1896 and 1897. The composition of these different parts of the plant at

different dates is given in tables. The results in the following table were obtained in 1897:

Total weight and weight of dry matter of leaves, stalks, and ears of 200 stalks of dent corn.

	Total weight.				Dry matter.			
	Leaves.	Stalks.	Ears.	Total.	Leaves.	Stalks.	Ears.	Total.
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
August 10	184.0	187.50	22.50	394.00	34.48	31.74	1.69	67.91
August 25	197.0	207.50	110.50	515.00	32.36	48.91	26.20	127.47
September 6	181.0	191.75	150.00	522.75	33.65	44.85	56.37	154.87
September 15	128.5	163.50	154.75	446.75	42.77	38.13	71.56	152.46

From investigations to ascertain when corn contains the largest amount of nutriment the results in the following table were obtained:

Yields per acre of green fodder, dry matter, and nutrients.

Date.	Stage of growth.	Green fodder.	Dry matter.	Protein.	Nitrogen-free extract.	Fat.	Fiber.
		<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
August 10	Tasseled ...	21,203	3,670.24	472.73	1,828.15	67.90	1,010.05
August 25	Roasting ...	25,493	5,320.39	576.08	3,212.45	143.11	1,148.67
September 6	Glazing	25,865	7,110.29	711.03	4,554.14	199.08	1,294.78
September 15	Ripe	23,007	8,020.24	696.96	5,356.72	242.61	1,413.17

The results show that "to secure the greatest yields per acre of valuable nutrients the corn should not be harvested until fully glazed and until the early ears are well ripened."

An experiment was made to ascertain the losses in the silo with corn cut at different stages of growth. The results are tabulated below:

Losses of original substance and dry matter in the silo.

Date.	Corn		Loss.	Loss.	Dry matter		Loss.	Loss.
	put in.	Taken out.			put in.	Dry matter taken out.		
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Per ct.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Per ct.</i>

In a discussion of the best time for cutting corn, the author quotes the results from a number of other stations.

Fertilizer, culture, and variety experiments on corn, R. J. REDDING (*Georgia Sta. Bul.* 37, pp. 35-63).—The work comprised variety tests, fertilizer tests, distance experiments, and a comparison of subsoiled and unsubsoiled plats. The results are reported in tabular form. Meteorological data for 1897 are given. Similar work has been formerly reported in Bulletin 30 of the station (E. S. R., 7, p. 943).

Fifteen varieties of corn were tested this season. The author considers further testing necessary before commenting on the results.

Shaw Improved and Higgin Improved are the only varieties tested for six years in succession and are considered as being uniform and persistent in yield.

A general fertilizer test proved unsatisfactory. It is stated that previous tests have indicated that, in a commercial fertilizer for corn on an average soil of middle Georgia, available phosphoric acid, potash, and nitrogen should be in the relative proportion to each other of 7: 1.3: 3.4, which would be secured in a mixture of 1,000 lbs. acid phosphate, 50 lbs. muriate of potash, or 200 lbs. of kainit, and 1,000 lbs. of cotton-seed meal.

The results of the distance experiments confirm the general conclusions drawn from previous experiments that "the more nearly the area of soil appropriated to each individual plant approaches the form of a square the greater will be the yield." Spacing the plants at different distances in rows of uniform width resulted in better yields from corn planted 4 by 3, with one plant in the hill, than when planted 4 by 2 or 4 by 4.

An experiment with subsoiled and unsubsoiled land for corn indicated that "subsoiling of the land covered by the experiment was not profitable." Subsoiling produced no appreciable effect.

Abstracts from former bulletins and the condensed reports on variety tests of cotton, the results of which are soon to appear in bulletin form, are given.

Fertilizer, culture, and variety experiments on cotton, R. J. REDDING (*Georgia Sta. Bul.* 39, pp. 107-135, pl. 1).—These experiments are a continuation of work formerly reported in Bulletin 35 of the station (E. S. R., 9, p. 127). The results of the experiments and the meteorological data for the season are given in tables. Fertilizer formulas for various crops, with directions for mixing and applying them, are appended.

Among 21 varieties of upland cotton, Nancy Hanks, Texas Bur, Jackson "Limbless," and Culpepper Improved ranked highest in the value of lint and seed, in the order mentioned. Nancy Hanks, yielding 1,473 lbs. of seed cotton per acre, stood first in the yield of seed and lint, matured earlier and proved most profitable. Strickland Improved produced the largest bolls and Texas Oak and Jackson "Limbless" yielded the largest percentage of lint (37.1 per cent). King Improved, a small balled, small seeded, early variety, and Strickland Improved, a large balled, large seeded, late variety, yielded on an average of 7 plats each, 1,134 lbs. and 1,349 lbs. of seed cotton per acre respectively. A number of varieties, including Jackson "Limbless," are described in detail, and the address of the dealers in different varieties of cotton seed are given.

Distance experiments have been made for seven consecutive years. Plants were placed 1, 2, 3, and 4 ft. apart in rows 4 ft. apart. This year the best yield was obtained with a distance of 3 ft. between plants,

while on an average for seven years a distance of 1 ft. has given the best results. "In five of the seven years the most productive plats were those planted 4 by 1 and 4 by 2." Subsoiling in connection with these experiments proved ineffective. An experiment carried on for four years to ascertain the relation between the width of the rows and the distance between the plants when allowing 6 sq. ft. for each plant led to the conclusion from the average results for the period that the distance between rows should be little if any greater than the spaces between the plants in the row. The distances between the rows were 3, 4, 5, and 6 ft. and those between plants in the row 12, 14.4, 18, and 24 in. The average results show a regular increase in yield from the 6 ft. by 2 in. plats to the 3 ft. by 24 in. plats.

Four different fertilizer tests were made. As between applying all the fertilizer before planting or applying part of it before planting and part of it at planting time, the results indicated no advantage in dividing the fertilizer. A comparison of raw bone meal and acid phosphate showed that raw bone meal was not a profitable source of phosphoric acid. A general fertilizer test was made on 17 plats. The normal application consisted of 468 lbs. acid phosphate, 32 lbs. muriate of potash, 208 lbs. of cotton-seed meal, and 32 lbs. nitrate of soda per acre. On some of the plats the various constituents were increased 50 per cent, but the amount of nitrate of soda remained constant in all cases. On plats which had received 50 per cent more of each of the three ingredients at an increased cost of \$2.63 per acre the increase in the yield of seed cotton per acre over the plats which had received the normal application was only 23 lbs. The results show that the application of 468 lbs. of acid phosphate, 36 lbs. muriate of potash, and 286 lbs. of cotton-seed meal gave better financial results than any other proportions used in these experiments. Drilling and bedding on the fertilizers gave slightly better results than applying them broadcast.

The effect of various potash salts on the composition and yield of potatoes, T. PFEIFFER, E. FRANKE, O. LEMMERMANN, and H. SCHILLBACH (*Landw. Vers. Stat.*, 49 (1897), No. 4-5, pp. 349-385).—A series of experiments were conducted to ascertain the effect of equal amounts of potash in various forms. The experiments made in 1894 led to no conclusions. In 1895 the work was continued in thirty-six pot and twelve plat experiments. Each pot contained 27 kg. of poor, sandy soil. The plats were a square meter in size, each surrounded by a solid wall and containing an equal amount by weight of soil bedded on a layer of gravel. In each set of experiments a fixed quantity of fertilizing material containing no potash was applied. In addition, 1 or 2 gm. of potash in the different forms mentioned below was applied to each pot and 15 gm. to each plat. The application of magnesium chlorid in connection with sulphate of potash and the application of kainit supplied equal amounts of chlorine. In 1896 the investigation was continued on the plats to ascertain the effects of the crude potash salts on the succeeding crop.

In the following table are the average results obtained from several pots in the pot experiments and from two plats in the plat experiments:

Yield of tubers and starch in 1895 and 1896 and a comparison of their production with and without potash.

Kind of potash fertilizer.	Potash applied per pot.	Yield per pot and per plat, 1895.				Increase (+) and decrease (-) of tubers and starch, calculated per acre, compared with yields obtained without potash, 1895.				Yield from plats, 1896.

The amount of potash, lime, magnesia, chlorin, and sulphuric acid in the tubers and in the stems and leaves, and the amount of starch in the tubers is given in tables.

The following table gives the average mineral constituents of the fresh tubers for both seasons:

Average mineral constituents of fresh potatoes.

	Potassium oxid.	Calcium oxid.	Magnesium oxid.	Chlorin.	Sulphuric acid.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
1895.....	0.506	0.016	0.039	0.067	0.095
1896.....	.524	.013	.038	.022	.084

It is suggested that the low yields in 1896 and the small chlorin content for the same year, which showed itself in the stems and leaves, may possibly be connected, but that from a single experiment no such conclusion could be safely drawn. From the results obtained the authors draw the following conclusions:

Potassium chlorid applied immediately before planting potatoes in quantities furnishing up to 250 kg. of potash per hectare (about 220 lbs. per acre) is as beneficial as an application of the sulphate supplying the same amount of potash. Under these conditions the chlorin contained in the chlorid is not detrimental to the growth of the plants.

The same amount of potash in the form of crude salts applied in the spring is of no benefit, and may even diminish the yield of starch. This is caused, on the one hand, by the high chlorin content of the crude salts, and, on the other, by the presence of magnesium compounds, especially magnesium chlorid. An insufficient amount of chlorin in the soil may influence the growth of the potato plant in such manner that the application of chlorids may be of direct benefit. Large yields of starch have been obtained even with a high chlorin content in the entire potato plant. It seems possible, therefore, that new varieties of potatoes may be bred, which are able to use larger amounts of chlorin, or may even be in need of larger amounts to produce a maximum yield. Strictly speaking, the results apply only to the variety ("Prof. Maereker") which was grown in this experiment.

Experiments with wheat, C. C. GEORGESEN, F. C. BURTIS, and D. H. OTIS (*Kansas Sta. Bul.* 71, pp. 163-174).—The series of experiments reported consisted of growing wheat continuously without manure, growing it in rotation, comparing subsoiled with surface-plowed land, different times of seeding, and testing a number of varieties. A severe frost during the latter part of November interfered materially with the results. Work along this line has been reported in Bulletin 59 of the station (E. S. R., 8, p. 594).

An acre plat, which was in wheat continuously for seventeen years without manure, gave an average yield of 19.57 bu. per acre for the period. During this period three crops were complete failures and two others but little short of failures owing to winterkilling.

An experiment with subsoiled and surface-plowed plats resulted in lighter yields on the subsoiled plats. Another experiment in this line, and in continuation of one formerly reported (E. S. R., 8, p. 594), resulted generally in smaller yields on plats subsoiled in 1894 than on plats which had been only surface plowed. The experience of the college farm with subsoiling for wheat and corn indicated that there is a positive loss of labor and yield by subsoiling.

The comparison of different dates of seeding showed that in general the best results were obtained from seedings made from September 7 to 21. On the average the seeding of September 16 made the best showing.

The rotation experiments have not been in progress long enough to warrant definite conclusions. They have shown, however, that a yearly application of 20 tons of barnyard manure per acre causes an excessive growth of straw and fails to develop the kernel. This year wheat was sown after some catch crops of soy beans and cowpeas. The best yields were obtained from the wheat seeded on soy-bean stubble.

Out of 57 varieties grown at the station for several years only the Turkey, Tasmanian Red, and Crimean have withstood the severe frosts in November so as to yield at the rate of 10 bu. or more per acre.

The sugar beet in Illinois, P. G. HOLDEN and C. G. HOPKINS (*Illinois Sta. Bul.* 49, pp. 52, figs. 13).—This bulletin reports the results

of culture experiments with sugar beets carried on at the station and throughout the State, gives instructions for sugar-beet culture, discusses other points of interest in this connection, such as the cost of production of the beets and their manufacture into sugar, and points out how Illinois is adapted to the production of beet sugar. The results of the experiments, meteorological data from 1889 to 1897, inclusive, and statistics for various beet-sugar producing countries are given in tables.

At the station the original Kleinwanzleben gave the best results. The beets averaged over 1 lb. in weight and contained about 15 per cent of sugar with a purity of 85. Improved Kleinwanzleben and Short French gave satisfactory results, while Long French was medium in quality. In no case did the sugar in the juice fall below 12 per cent or the coefficient of purity below 80. Analyses made of beets harvested weekly for a period of ten weeks, beginning September 14, showed that in general there was an increase in the sugar content and the purity as the season advanced. Plowing 8 and 10 in. deep showed no marked difference in the results, but samples from land subsoiled 16 in. deep were lower in purity than samples from unsubsoiled plats. Beets grown in rows 15, 18, 22, 28, 36, and 44 in. apart decreased in sugar content and purity as the distance between the rows increased.

The sugar beet in Indiana, H. A. HUSTON and J. M. BARRETT (*Indiana Sta. Bul.* 68, pp. 32, figs. 13).—This bulletin discusses the method of growing sugar beets, the necessary climatic conditions, the factory requirements, and the results of cultural experiments made in the State in 1897. Meteorological data and analyses of beets grown in 35 different counties are tabulated. The results of the analyses show a wide range, but in every county from which more than one sample was received, beets of a satisfactory character were produced. In very many cases the work was not properly done and many samples were received from parties who did not get their seed from the station and who had no knowledge of the proper methods of sugar-beet culture. "What has been accomplished already seems to indicate that, taking everything into consideration, Indiana will be found admirably adapted to the production of the sugar beet, but the fact is not yet proven."

Sugar-beet investigations, J. L. STONE, L. A. CLINTON, G. C. CALDWELL, G. W. CAVANAUGH, ET AL. (*New York Cornell Sta. Bul.* 143, pp. 493-574, figs. 9).—This bulletin contains general remarks on sugar-beet cultivation and reports of fertilizer experiments and cooperative culture tests with sugar beets. Notes are given on the condition and preparation of the soil, seeding, thinning, tillage and harvesting the crop.

Fertilizer experiments were made at the station to determine the effect of different fertilizers on the yield and quality of sugar beets. The plats, 14 in number, were 4 by 5 ft. in size, each surrounded by a brick and cement wall to avoid the transportation of fertilizer material from one plat to another. For three years previous the soil had been

cropped heavily without the application of any fertilizer. The different fertilizers were applied singly and in various combinations. Kleinwanzlebener seed was planted May 19 and later on the beets were thinned to 28 plants per plat. Analyses were made October 4, 9, and 20 and November 6 and 27, and in general it may be said there was an increase in the sugar content and purity from the first to the last analysis. The largest yield was obtained from the application of untreated phosphate rock, the highest percentage of sugar from the application of muriate of potash, and the highest coefficient of purity from the use of a complete fertilizer; but, on the whole, the effect of the various fertilizers was not very marked.

Cultivating beets five or seven times during the season gave practically the same results; and cultivating weekly from June 1 to September 5 indicated no appreciable gain over cultivating once every two weeks during the same period.

The analysis of samples from the cooperative experiments is described in detail and the results are given in tabular form. Analyses of the upper and lower halves of beets showed that the upper halves were richer in sugar, while the purity, with one exception, was higher in the lower. It was found that in pressing beet pulp the juice which first ran from the press was lower in sugar content and purity than that from the last part of the operation; hence the authors advise when making analyses to express as much as possible from the pulp. Analyses of 112 samples of beets grown on sandy loam averaged 16.66 per cent of sugar in the juice, with a purity coefficient of 83.1; while 109 analyses of beets grown on clay loam gave an average sugar content of 17.29, with a purity coefficient of 83.8. The distance between rows had no effect on the quality of the beets. Plats which had received barnyard manure the previous year produced beets higher in sugar content and purity than plats which had received barnyard manure the same season the beets were grown. The effects of previous crops, as pointed out, are in favor of untilled grain crops as compared with hay, potatoes, corn, and cabbage, but the difference in the quality of beets grown after these crops was small. A series of analyses, made to determine the influence of size of beet on sugar content and purity, showed that in general the smaller the beet when matured the higher the sugar content and coefficient of purity. Beets ranging from $1\frac{1}{4}$ to 2 lbs. are considered to be most profitable.

In one experiment the crowns were removed from the beets and analyzed separately. The seven analyses reported show on an average a sugar content of 12 per cent and a coefficient of purity of 73.07 for the crowns, and a sugar content of 13.9, with a purity coefficient of 80.4, for the beets below the crown.

The following table is based on the results of experiments:

Relative amounts of leaves, crowns, and crownless beets per ton of whole crop and the content of plant food.

	Proportion of parts.	Composition of parts.		
		Nitrogen.	Potash.	Phosphoric acid.
	Pounds.	Pounds.	Pounds.	Pounds.
Fresh leaves.....	520	3.33	5.67	0.59
Crowns.....	340	1.46	1.53	.41
Fresh crownless beets.....	1,140	3.19	4.10	1.28
Total.....	2,000	7.98	11.30	2.28

The composition and production of sugar beets, L. L. VAN SLYKE, W. H. JORDAN, and G. W. CHURCHILL (*New York State Sta. Bul. 135, pp. 513-572*).—This bulletin discusses the conditions required for the successful growth of sugar beets and the outlook for the sugar-beet industry in the State of New York, and gives a report of the culture experiments made with sugar beets at the station and in various parts of the State.

About 140 samples of Kleinwanzlebener and Vilmorin Improved beets, grown under favorable climatic conditions in various parts of the State, varied from 12.7 per cent to 19.6 per cent of sugar in the juice, giving an average of 16.1 per cent, with an average coefficient of purity of 82.5. The average weight of one beet was 16.5 oz.

The experiments at the station showed the cost of producing an acre of beets, based on hand labor at \$1.25 per day and team at \$3.50 per day, and hand labor at 75 cts. and team at \$3.00 per day, to be \$75.80 and \$54.30, respectively. The yield was about 16.25 tons per acre; but for 1,000 lbs. of beets the loss of weight by removing the crowns was 73 lbs., and by washing off the dirt, 49 lbs., giving a yield of 15.1 tons of marketable beets per acre. The beets contained 16 per cent of sugar in the juice, with a coefficient of purity of 81. The average weight of one beet was 12 oz. A portion of the land was fertilized with 250 lbs. of sulphate of potash, 300 lbs. acid rock, 200 lbs. dried blood, and 200 lbs. nitrate of soda per acre, which increased the yield about 6 tons per acre over the unfertilized portion of the field. This increase is considered to pay for at least twice the amount of fertilizer used.

Sugar beets in South Dakota, J. H. SHEPARD (*South Dakota Bul. 56, pp. 32, map 1*).—This bulletin discusses the resources and facilities of South Dakota for the manufacture of beet sugar and gives a report of the cooperative culture experiments with sugar beets for 1897. A description of ten regions of the State, differing from each other in vegetation and crop conditions, is given. Meteorological data for the growing season of 1897, analyses of well water, chemical and mechanical analyses of soils, and the results of sugar beet experiments are

given in tables. The work of previous years in this line is briefly reviewed.

The average sugar content in the juice for the different regions ranged from 14.7 to 19.6, and the coefficient of purity from 81.6 to 87.8. The average for the ten regions was 16.4 per cent of sugar in the juice, with a purity of 85.6. Analyses were made of 951 beets, averaging 383 gm. in weight.

The results of a test of five foreign varieties made at the station are given in a table.

Utah sugar beets, 1897, J. A. WIDTSOE (*Utah Sta. Bul.* 53, pp. 87-115).—In this bulletin the mean temperature and the precipitation at the station for each month for the years 1891 to 1897, inclusive, and the results of cooperative culture experiments with sugar beets are given in tables. Of the samples analyzed 211 were grown in eight different counties, 4 were received from Idaho, and 54 were taken from the station farm. These 269 samples showed an average of 14.24 per cent in the juice, with a purity coefficient of 83.1.

Field experiments, C. D. SMITH (*Michigan Sta. Rpt.* 1896, pp. 110-111).—An outline is given of experiments conducted on the college farm during the year. The details are published in other publications of the station (*E. S. R.*, 8, pp. 882, 883; 9, p. 131).

Subsoiling experiments (p. 114).—Of three plats of sandy soil the first was plowed 4 in. deep, while the other two were plowed 8 in. deep, but one of these was subsoiled 6 in. below the furrow. In 1895 and 1896 all plats were planted to corn. The second year the depth of plowing for all plats was 6 in. The first year was unusually dry, while the second year was unusually wet. The subsoiled plat produced a slightly better yield than the plat not subsoiled in 1895, but the second year there was no apparent gain.

In addition the article contains accounts of dynamometer tests and observations on the shrinkage of cord wood (p. 195).

On the possibility of improvement of agricultural plants, H. NILSSON (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, I, pp. 454-457; II, App. 16, pp. 40, ill.*).

Report of the Department of Agriculture, New Brunswick, 1897, C. H. LABILLOIS (*Rpt. on Agr. for New Brunswick, 1897, pp. 1-100*).—The crops of 1897 under general cultivation in the province are briefly described and the meteorological data for the season tabulated. The reports and accounts of 51 agricultural societies for the year are given.

Planting at different depths, P. G. HOLDEN, F. P. CLARK, and A. A. CROZIER (*Michigan Sta. Rpt.* 1896, pp. 200, 201).—A reprint from Bulletin 125 of the station (*E. S. R.*, 7, p. 395).

Alfalfa, H. HUTIER (*Jour. Agr. Prat.*, 62 (1898), No. 17, pp. 601-603).—An article discussing the extent of alfalfa culture in France and the value of the crop as a feeding stuff.

Alfalfa, A. A. CROZIER (*Michigan Sta. Rpt.* 1896, pp. 197, 198).—A reprint from Bulletin 125 of the station (*E. S. R.*, 7, p. 396).

Variations in the hereditary ability of certain characters in the hybridization of barley, P. BOLIN (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, II, App. 11, pp. 12*).

Studies on variation and improvement, with special reference to Goldthorpe barley, W. JOHANNSEN (*Ugeskr. Landm.*, 43 (1898), No. 11, pp. 140-142).

American red clover (*Fühling's Landw. Ztg.*, 47 (1898), No. 5, pp. 237-239).

Crimson clover in Michigan, A. A. CROZIER (*Michigan Sta. Rpt. 1896*, pp. 171-180).—A reprint from Bulletin 125 of the station (E. S. R., 7, p. 382).

Bokhara clover (*Melilotus altissimus*) (*Deut. Landw. Presse.* 25 (1898), No. 44, p. 350).

The common names of the clovers, A. A. CROZIER (*Michigan Sta. Rpt. 1896*, pp. 181-196).—A reprint from Bulletin 125 of the station (E. S. R., 7, p. 396).

Clover sown every month in the year, A. A. CROZIER (*Michigan Sta. Rpt. 1896*, pp. 181, 182).—A reprint from Bulletin 125 of the station (E. S. R., 7, p. 396).

Detasseling corn, C. D. SMITH, A. A. CROZIER, and J. T. BERRY (*Michigan Sta. Rpt. 1896*, pp. 205-208).—A reprint from Bulletin 125 of the station (E. S. R., 7, p. 383).

Cattle ranges of the Southwest: A history of the exhaustion of the pasturage and suggestions for its restoration, H. L. BENTLEY (*U. S. Dept. Agr., Farmers' Bul.* 72, pp. 32, figs. 9).—This is a popular bulletin in which the early use and present condition of Texas pastures are described, methods of how to renew the stock ranges suggested, and the obstacles to be overcome in their renewal pointed out. Descriptive notes are given on the following promising grasses and forage plants native in the Southwest: Bermuda grass (*Cynodon dactylon*), black grama (*Hilaria mutica*), buffalo grass (*Bulbili, dactyloides*), Colorado grass (*Panicum texanum*), curly mesquite (*Hilaria cenchrroides*), ground plum (*Astragalus crassicaarpus*), needle grass (*Aristida fasciculata*), side-oats grama (*Bouteloua curtipendula*), stolley vetch (*Vicia leavenworthii*), tallow weed (*Actinella linearifolia*), western wheat grass (*Agropyron spicatum*), blue grama (*Bouteloua oligostachya*), and wild bean (*Phaseolus helvolus*). "Native grasses are by far the best for home use. They are suited to the climate and the climate is suited to them."

Profitable fodder crops, C. H. GORMAN (*Agr. Gaz. New South Wales*, 9 (1898), No. 3, pp. 281-283).—Popular notes on alfalfa and sorghum.

Potash and phosphoric acid fertilizers for meadows, A. RINDELL (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897*, I, pp. 312-320).

Hops, R. H. McDOWELL (*Nevada Sta. Bul.* 35, pp. 24).—This is a popular bulletin on hop culture, with general directions for the cultivation, harvesting, curing, packing, and marketing of the crop.

Characteristics of various lupine varieties (*Deut. Landw. Presse.* 25 (1898), No. 40, pp. 436, 437, figs. 11).—Seven varieties of lupines are described.

Modiola (*Pacific Rural Press.* 55 (1898), No. 19, p. 289).—Notes on this forage plant, newly introduced from Chile into California. The plant has been identified as *Modiola decumbens*.

The oats supply of the United Kingdom (*Jour. Ed. Agr. [London]*, 5 (1898), No. 1, pp. 25-28).

Potatoes, L. R. TAFT (*Michigan Sta. Rpt. 1896*, pp. 341-349).—A reprint from Bulletin 131 of the station (E. S. R., 8, p. 216).

Raising rice without water (*Jour. Jamaica Agr. Soc.*, 2 (1898), No. 5, p. 203).—A short note on this method of rice culture.

The beet sugar industry and its development in California, E. W. HILGARD (*Pacific Rural Press.* 54 (1897), No. 22, p. 341).—A discussion of sugar beet culture and factory operations in the manufacture of beet sugar, with notes on the development of the industry.

Cultivation of the soil for sugar beets (*Pacific Rural Press.* 55 (1898), No. 19, p. 292).—Popular notes on preparation and cultivation of the soil for sugar beets in southern California.

The sunflower (*Jour. Jamaica Agr. Soc.*, 2 (1898), No. 5, pp. 184-186).—Directions for the cultivation and utilization of sunflowers are given in a popular manner.

Tobacco culture, W. SAUNDERS (*Canada Cent. Expt. Farm Bul.* 30, pp. 14).—This bulletin contains historical notes on the tobacco plant and directions for its culture.

The methods of cultivating and harvesting the crop and preparing it for market are discussed and insect remedies suggested. Some of the earliest and best yielding varieties tested at the Central Experimental Farm are White Barley, Connecticut Seed Leaf, Pennsylvania Seed Leaf, Fryer Yellow, Climax, Yellow Mammoth, Oronoko Yellow, Safrano, Brazilian, and Canadian.

Tobacco as a perennial, W. DAROCZI (*Jour. Jamaica Agr. Soc.*, 2 (1898), No. 5, pp. 197-199).—It is reported that tobacco can be grown as a perennial and that each succeeding crop is heavier and of better quality when so grown.

Methods of curing tobacco, M. WHITNEY (*U. S. Dept. Agr., Farmers' Bul.*, 60, pp. 15).—A revised edition (E. S. R., 9, p. 718).

Fodder turnips, H. L. DE VILMORIN (*Jour. Agr. Prat.*, 62 (1898), No. 22, pp. 790-792, pl. 1).—A popular article on fodder turnips, with notes on the principal varieties.

The cultivation of grain, G. HEUZÉ (*Jour. Agr. Prat.*, 62 (1898), No. 18, pp. 647-649).—A discussion on the cultivation of drilled grain during the period of growth.

Four years variety tests with winter wheat, A. SEMPOLOWSKI (*Deut. Landw. Press.*, 25 (1898), No. 38, p. 412).—Tabulated reports of the experiments are given, with notes on the different varieties.

Harvesting wheat at successive stages of ripeness, P. G. HOLDEN and L. J. BRIGGS (*Michigan Sta. Rpt.*, 1896, pp. 202-204).—A reprint from Bulletin 125 of the station (E. S. R., 7, p. 395).

Manuring of our modern highly improved varieties of wheat, M. MAERCKER (*Braunsch. Landw. Ztg.*, 56 (1898), No. 18, p. 77).—A discussion of the results of fertilizer experiments and variety tests. The newly improved square head varieties of wheat gave better results than the older square head varieties.

Rotation of crops (*Agr. Jour. Cape of Good Hope*, 12 (1898), No 7, pp. 365-369).—A general discussion on crop rotations with special reference to seven and four year systems.

HORTICULTURE.

Vegetable growing, S. C. MASON and W. L. HALL (*Kansas Sta. Bul.*, 70, pp. 135-162, pls. 5).—Detailed directions are given for the construction and use of hotbeds and cold frames.

The results obtained in the cultivation of the cauliflower at the station are given. Manure applied to the soil at the rate of 50 loads per acre before setting the plants did not increase the yield very noticeably. Figures are given illustrating the tendency of cauliflower to form compact white heads during the cool part of summer and to form less compact dark colored heads during the warm weather later in summer. Early Snowball cauliflower matured earlier, produced more and larger heads than the Early London, and the heads were of better quality.

Methods of growing cabbage to get early maturity are reported. By one method the plants are started in the fall and kept in protected cold frames over winter. By another method they are started in winter in the greenhouse or hotbed.

A table is given comparing the yield of ten varieties of asparagus on manured and unmanured soil. The varieties giving the greatest yield were the Hub and Donald Elmira. A fairly successful method of forcing asparagus under greenhouse benches is described. Of the varieties forced Donald Elmira gave best results.

A method followed by English gardeners to increase the earliness of potatoes was tested. The tubers were packed in sand in greenhouse flats with the "seed" end exposed above the sand. The flats were placed under the bench in a cool propagating house late in February. A month later, when the tubers had sprouted, they were set in furrows in the field in the same position they had in the flats. At the same time unsprouted tubers were planted as a check. Tables are given showing the comparative yield of ten hills of the sprouted and unsprouted lots dug June 16 and of the remainder dug July 24. The authors say "it will be observed that the proportional difference is greater with the early digging than the later, and that the difference in the ripe tubers would not be sufficient to make the experiment pay for the trouble. The real gain was found in the examination made June 1, which gave table potatoes a week ahead of the ordinary method."

In 1893 a large number of varieties of onions were tested, of which Prize Taker gave the best results. In 1894 a fertilizing experiment was made with onions. A heavy application of barnyard manure gave better results than any of the more concentrated fertilizers. In 1895 tests of subsoiling and irrigating were made in connection with onions. The yield of onions on a subsoiled and unirrigated plat was about 103 lbs.; on an irrigated and nonsubsoiled plat, 167 lbs.; on a plat neither irrigated nor subsoiled, 173 lbs.; and on a plat both subsoiled and irrigated, 244 lbs. In 1896 the experiment was continued, but thrips ruined the crop entirely. In 1897 a comparison of the old *vs.* the new onion culture was made. The yields by the two methods are given in a table. No conclusions are drawn. Most of the onions were of inferior size, owing to injury from thrips.

A test was made of different grades of soil for forcing lettuce. The soil varied from poor garden loam to a mixture of one-fourth sand and three-fourths garden loam. A number of plantings were made. The earliest plantings gave the best results in the mixture of half sand and half loam, the next later planting gave best results in soil one-fourth sand and three-fourths loam, and the latest planting gave best results in the poor loam. A test was also made of varieties. Bartelde Denver Market gave the heaviest heads, Grand Rapids next heaviest, and Black Seeded Simpson lightest. Plants set 6 by 6 in. apart gave a greater yield per square foot of bench than plants set 8 by 8 in.; but the average weight of the heads was considerably less in the former case than in the latter.

The method of forcing tomatoes at the station is given, and the treatment of Oedema considered. The yield from 30 plants of each of the following varieties was: New Stone, 86.5 lbs.; Fordhook First, 66.5 lbs.; Royal Red, 65.7 lbs.; Dwarf Champion, 60.3 lbs.

Watermelons, H. N. STARNES (*Georgia Sta. Bul.* 38, pp. 67-103, pls. 3, figs. 5).—The bulletin discusses watermelon culture, including soils, fertilizers, planting, cultivation, gathering, marketing, seed saving,

insect enemies, varieties, and similar topics; reports the results of fertilizer and variety tests in 1895 and 1897, and describes 40 varieties.

The results of fertilizer and variety tests are given in tables. The results of the fertilizer test of 1895 were not conclusive on account of irregularities in the land on which the plants were grown. In 1897, superphosphate, nitrate of soda, cotton-seed meal, muriate of potash, and kainit were used in varying amounts and in different combinations. In the author's opinion, the results of this work, though much more conclusive than the previous work, are not altogether satisfactory. A moderate amount of fertilizers gave better results than a larger amount. As a source of nitrogen, nitrate of soda gave a larger early yield, a greater total yield, and somewhat larger fruit than cotton-seed meal. In a similar way, muriate of potash proved superior to kainit as a source of potash.

In 1895 25 varieties and in 1897 30 varieties of watermelons were tested. The data obtained are recorded in tables. The results of the two years were very different. For instance, the variety (Lord Bacon), which in 1895 ranked first in yield and second in size, in 1897 dropped to twenty-first in yield and sixth in size, while Augusta Sugar Loaf, which in the former test ranked twenty-third in yield and twenty-first in size, in the latter test ranked second in yield and seventeenth in size.

Strawberries: Cultural notes and variety tests, W. J. GREEN (*Ohio Sta. Bul.* 85, pp. 24, pls. 3).—The author believes that while good varieties are of the utmost importance to strawberry growers, and while the highest standards have not been reached, nevertheless there is danger of making the variety question too prominent. Intensive culture should be given more attention. To secure the finest berries where sufficient water is at hand, summer planting is recommended. The plants are set in triple rows in imitation of the matted row. By thinning beds set in the spring, plants can be obtained for the summer planting.

Notes are given on 70 varieties of strawberries, summarizing the behavior of each for the whole time it has been on trial at the station. The following varieties are recommended for general culture: Bubach, Brandywine, Greenville, Haverland, Lovett, and Warfield. The most promising new varieties are: Aroma, Anna Kennedy, Beauty, Copernicus, Clyde, Carrie, Enormous, Glen Mary, Hall Favorite, Portage, Ruby, Rio, Staples, Tennessee Prolific, and three unnamed seedlings.

Practical advice on the hybridization of the grape, P. CASTEL (*Prog. Agr. et Vit.*, 29 (1898), No. 15, pp. 462-468).—This is a summary of a series of articles on the hybridization of grapes.

In regard to the choice of parent plants for hybridizing the author gives the following rules:

(1) Plants should be chosen which present in the greatest degree possible those characteristics desired in the resulting hybrid. (2) The

parent plants should be hybridized in such way as to utilize the characteristics of each to the best advantage; for instance, to obtain direct producers, American species of grapes should be pollinated by French grapes, while to obtain stocks for grafting the reciprocal hybrid should be obtained. (3) Parent plants should be chosen which will give the maximum of variation to the seedlings. (4) In the production of hybrids or crosses the maximum of vigor and fertility should be maintained by the constant introduction of unrelated species or varieties.

The problems of modern viticulture, the author says, are as follows:

(1) To obtain new stocks for grafting, which shall exhibit great resistance to phylloxera, adaptation to calcareous soils, affinity for scions of French grapes, and such other characters as tend to facilitate their culture; (2) to obtain direct producers, which shall show great resistance to phylloxera, adaptation to the soil to be used, a high sugar content, fruitfulness, early maturity, resistance to fungus diseases, fruit of good quality and color, and any characteristic facilitating their culture; (3) to obtain new varieties resistant to black rot.

Report of the horticulturist, L. R. TAFT (*Michigan Sta. Rpt. 1896, pp. 114-119, charts 3*).—This report gives general outlines of the work of the department during the year, the results of the various experiments being published in bulletin form. The arrangement of orchards at the station and substation is described and illustrated by charts.

Education of horticulturists, L. R. TAFT (*Michigan Hort. Soc. Rpt. 1896, pp. 220-226*).

Cocoa culture in Samoa, H. J. MOORS (*U. S. Consular Rpts. 1898, No. 212, pp. 65-68*).

Market gardening with limited capital, H. W. COLLINGWOOD (*Massachusetts State Bd. Agr. Rpt. 1897, pp. 65-94*).

New creations in the vegetable kingdom, D. W. BEADLE (*Canad. Hort., 21 (1898), No. 6, pp. 217-224, pl. 1, figs. 8*).—Remarks on how improvement of plants is effected and examples of results secured in the improvement of plants by the horticulturists of Ontario.

Rotations in vegetable gardening, A. MAGNIEN (*Jour. Soc. Nat. Hort. France, Congrès Hort. 1898, pp. 22-35*).

Rotations in vegetable gardening, J. FOUSSAT (*Jour. Soc. Nat. Hort. France, Congrès Hort. 1898, pp. 36-51*).

On the improvement of peas, H. TEDIN (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, II, App. 12, pp. 25*).

Horse-radish, M. G. KAINS (*U. S. Dept. Agr., Division of Botany Circ. 15, pp. 8*).—A discussion of the culture, uses, enemies, yield, and profits of horse-radish.

The history of the radish, G. HENSLAW (*Gard. Chron., 3. ser., 23 (1898), No. 600, p. 389*).

Vegetable tests, H. P. GLADDEN and U. P. HEDRICK (*Michigan Sta. Rpt. 1896, pp. 350-374*).—A reprint from Bulletin 131 of the station (E. S. R., 8, p. 225).

The apple orchard, L. R. TAFT (*Michigan Sta. Spec. Bul. 4, pp. 1-12*).—A popular bulletin giving suggestions for the culture of apples.

Grafting the apple (*Nat. Nurseryman, 6 (1898), No. 5, p. 63*).—A reprint from E. S. R., 9, p. 750.

English orchards (*Jour. Bd. Agr. [London]*, 5 (1898), No. 1, pp. 1-10).—Notes on the present status of English orchards, with suggestions for their improvement.

Fruit list recommended for general planting in various fruit districts of Colorado (*Colorado Bd. Hort.*, 1897, pp. 147-152).

Experiments with orchard cover crops, J. CRAIG (*Michigan Hort. Soc. Rpt.*, 1896, pp. 275-280).—The author discusses the relative value of several cover crops as a winter protection to orchards and as green manures. The discussion is based on the results of experiments made at the Central Experimental Farm of Canada, and published in part previously (E. S. R., 9, p. 811).

Future of peach growing in the United States, J. H. HALE (*Michigan Hort. Soc. Rpt.*, 1896, pp. 287-306).

Pruning the peach, R. MORILL (*Michigan Hort. Soc. Rpt.*, 1896, pp. 310-325, figs. 12).

Relative hardiness of fruit buds of peaches and plums, J. CRAIG (*Michigan Hort. Soc. Rpt.*, 1896, pp. 361-366).—This article is also printed in Canada Expt. Farms Rpt. 1896 (E. S. R., 9, p. 811).

About thinning peaches, A. E. MICKLE (*Canad. Hort.*, 21 (1898), No. 6, pp. 225, 226).

Thinning Fruit (*California Fruit Grower*, 22 (1898), No. 22, pp. 6, 7).—A reprint from U. S. Dept. Agr., Farmers' Bulletin 73. (See p. 197.)

Fruits at the agricultural college, L. R. TAFT and H. P. GLADDEN (*Michigan Sta. Rpt.*, 1896, pp. 338-340).—A reprint of Bulletin 130 of the station (E. S. R., 8, p. 131).

Fruits at South Haven, T. T. LYON (*Michigan Sta. Rpt.*, 1896, pp. 286-327).—A reprint of Bulletin 129 of the station (E. S. R., 8, p. 131).

Raising and marketing of fruit, W. F. TABER (*Massachusetts State Bd. Agr. Rpt.*, 1897, pp. 119-140).

Evaporation from fruit trees (*Gard. Chron.*, 3, ser., 23 (1898), No. 597, pp. 337, 338).—The author reviews the work of J. B. Lawes, L. H. Bailey, and A. L. Kniseley on the evaporation of water from the twigs of trees in winter, and reports observations of his own on the evaporation from twigs of different sizes. The data are tabulated. The loss of water from the large twigs was greater than from the small ones, but the percentage of water lost was practically the same in all cases.

Studies in pollination, J. C. WHITTEN (*Missouri Hort. Soc. Rpt.*, 1897, pp. 101-103).—Lists of apples, peaches, plums, cherries, and grapes are given, showing the varieties which fruited and those which failed to fruit when their flowers were covered with sacks.

Fruits of the tropics (*Wiener Illus. Gart. Ztg.*, 22 (1898), No. 6, pp. 209-213).

A practical handbook of fruit-tree culture, J. BÖTTNER (*Praktisches Lehrbuch des Obstbaus. Frankfurt*, 1898, pp. 574, figs. 557).

Small fruits in the home garden, S. T. MAYNARD (*Massachusetts State Bd. Agr. Rpt.*, 1897, pp. 225-237, figs. 3).—Suggestions regarding culture of small fruits.

Strawberries, L. C. CORBETT (*West Virginia Sta. Bul.* 52, pp. 88-110, pls. 3).—Directions for the culture of strawberries are given and the results of variety tests in the years 1896 and 1897 are reported. The data obtained are given in tables. The rank of the different varieties as to size of fruit and productiveness for both years is shown by tables and by a chart. Descriptive notes are given on the varieties tested and a typical fruit of each is illustrated.

Irrigation of grapes, B. CHAUZIT (*Prog. Agr. et Vit.*, 29 (1898), No. 23, pp. 698-705).

Self-sterility among cultivated grapes, S. A. BEACH (*Michigan Hort. Soc. Rpt.*, 1896, pp. 64-68).—The data on which this paper is based were published in the Annual Report of the New York State Station for 1895 (E. S. R., 9, p. 52).

Observations during 1892-1897 at the viticultural station of Neauphle-le-Chateau, P. MOUILLEPERT (*Ann. Agron.*, 24 (1898), No. 5, pp. 215-253).

Viticulture and vinification in the province of Salta (*La viticultura y la vinificación en la Provincia Salta. Buenos Ayres*, 1897, pp. 69, pls. 7).

Azaleas for forcing, R. M. GREY (*Florists' Exchange*, 10 (1898), No. 19, pp. 480, 481).—Notes on culture and varieties of azaleas.

The chrysanthemum: Its culture and management. T. D. HATFIELD (*Amer. Gard.*, 19 (1898), No. 180, Sup., pp. 10, 11).

Single chrysanthemums (*Garden*, 53 (1898), No. 1381, pp. 386, 387, pl. 1).

Clematis (*Amer. Gard.*, 19 (1898), No. 178, pp. 390, 391, figs. 2).—Notes on various species.

Improvement of the gladiolus, H. H. GROFF (*Michigan Hort. Soc. Rpt.*, 1896, pp. 106, 107).

Crossing hellebores, T. H. ARCHER-HIND (*Garden*, 53 (1898), No. 1385, pp. 414, 415, pl. 1, fig. 1).—Notes on the author's experience in crossing hellebores.

How to make a lawn, H. C. IRISH (*Missouri Hort. Soc. Rpt.*, 1897, pp. 87-91).

Selection in its relation to horticulture. C. L. ALLEN (*Florists' Exchange*, 10 (1898), No. 24, p. 599).—A paper read before the Eastern New York Horticultural Society.

Ornamental trees and shrubs of the open air cultivated for their flowers, A. CHAURQUERAND (*Jour. Soc. Nat. Hort. France, Congrès Hort.*, 1898, pp. 113-123).

Ornamental trees and shrubs of the open air cultivated for their flowers, C. BALTET (*Jour. Soc. Nat. Hort. France, Congrès Hort.*, 1898, pp. 124-141).

Shrubs and their propagation (*Florists' Exchange*, 10 (1898), Nos. 18, p. 462; 19, p. 485; 20, p. 500; 23, pp. 574-575).

Park woodlands and plantations, J. W. PETTIGREW (*Amer. Florist*, 13 (1898), No. 526, pp. 1423, 1424).—A paper read before the Park and Out-door Art Association.

New evergreen hybrids from *Rosa wichuraiana*, R. M. GREY (*Florists' Exchange*, 10 (1898), No. 25, p. 623).

Systems and types of the ornamentation of gardens and their application, A. MAUMENÉ (*Jour. Soc. Nat. Hort. France, Congrès Hort.*, 1898, pp. 6-21).

Residential sites and environments; their conveniences, gardens, parks, planting, etc., J. F. JOHNSON (*New York: A. T. DeLamare*, 1898, ill.).—The book is divided into three parts. Part 1 treats of residential sites and environments, including such topics as thinning out woodlands, model home ground, beauties of plant life, special effect of trees and shrubs and of carpet plants. Part 2 is planting and introduction to undulations, and treats of planting and transplanting trees and large plants, mass planting, grouping in boundaries, planting borders, herbaceous garden, rockeries, aquatic and bog garden, perpetual effects, etc. Part 3 treats of villa gardens and public grounds under such heads as small gardens, corner lots, planting a church front, locating entrance roadways, planting a small garden, making the most of the back, a town square, etc.

Some 50 plans and diagrams are given.

DISEASES OF PLANTS.

Notes on some peach diseases, L. R. TAFT (*Michigan Sta. Rpt.*, 1896, pp. 120-124).—Notes are given on peach yellows, "little peach," root galls, and a gum disease of the peach.

The author calls attention to the fact that, while peach yellows is still prevalent in the State, by frequently cutting out the diseased trees the loss is reduced very materially, numerous instances being reported where not more than one tree in a thousand is annually condemned. Brief notes are given on spraying for the prevention of peach yellows; but, while the use of fungicides may have a beneficial effect on the general health of the trees, there is no evidence to show that it will prevent attacks of peach yellows. Numerous cases are given which may lead to a mistaken identification of peach yellows. Among

the principal ones are dry, hot weather, attacks of borers, overbearing lack of plant food, etc.

Under the name of "little peach" the author describes a disease which apparently is of unknown cause. The unhealthy trees were found on all kinds of soil, and as a rule but few trees scattered through an orchard were attacked. The diseased trees live for a number of years and in some cases make a partial recovery. The author has been unable to identify any fungus or bacteria with the disease, nor is he able to ascribe it to any positive cause. He thinks possibly cold weather in the fall or spring, following a season in which growth was continued late into the autumn, may bring about this trouble. An opportunity was offered in the spring of 1896 to test this theory. Some of the diseased trees examined showed an abnormal growth of wood for the season of 1893. Directions were given that these trees be cut back so as to remove the wood that had apparently been injured and thus form a new head from shoots that would be sent out below. Three trees which the owner thought "would die anyway" were thus pruned. They formed good heads during the summer and the following fall they were apparently the healthiest trees in the orchard. In other cases where the pruning was not sufficient to remove the injured wood "the benefits of the heading back were quite marked, but as the new shoots had to draw their nourishment through the injured tissue the results were less marked." The author states that in the case of 4-year-old trees under high cultivation the injury seemed to be about overcome in two years. A number of experiments have been undertaken with commercial fertilizers and it is said that in every case benefits can be seen from their use.

Brief notes are given on the occurrence of root galls on peaches, the galls being attributed to various causes, and, since such affected stock is worthless, the author advises against planting it.

Attention is called to the exudation of gum from the tissues of peach trees that have been injured by brown rot or other causes. Where patches of gum are numerous or large, it is recommended that the branches be cut off below the spots and proper attention given the trees to develop new shoots and ripen their wood.

The grain smuts: How they are caused and how to prevent them, W. T. SWINGLE (*U. S. Dept. Agr., Farmers' Bul. 75, pp. 20, figs. 8*).—The substance of this bulletin has already appeared as *Farmers' Bulletin 5* and in an article by the author in the *Yearbook of this Department for 1894*. The different smuts of grain are described and various treatments suggested for their prevention. A new fungicide for the prevention of oat smut is mentioned which, as the author says, has not yet been extensively tested for smuts, but it is thought it will prove effective. This fungicide, to which the name "Sar" solution has been given, consists of a mixture of flowers of sulphur, resin, caustic soda, and water. The formula given produces a sticky solution which

must be kept in tightly corked jugs or in closed barrels or casks. When ready for use, $1\frac{1}{2}$ pt. of the solution is added to 50 gal. of water and the seed soaked for 24 hours.

A bacterial rot of cabbage and allied plants, H. L. RUSSELL (*Wisconsin Sta. Bul.* 65, pp. 39, figs. 15).—This bulletin gives the completed results of the investigations of the author and his assistants, H. A. Harding and F. Cranfield. A sketch of this work was presented by the author in a paper read before the Association of American Agricultural Colleges and Experiment Stations, 1897. The author's investigations of this disease were conducted at the same time as those of E. F. Smith, which have been previously noted.¹ The conclusions of the two authors practically agree in the cause of the disease, biology of the organism, and methods of prevention.

Plant diseases in Holland, C. A. J. A. OUDEMANS (*K. Akad. Wetten. Amsterdam, 1897, June 26; abs. in Ztschr. Pflanzenkrank., 8 (1898), No. 1, p. 33*).—The author reports young peas attacked by *Brachyspora pisi*, n. sp.; leaves of rye affected by *Marsonia scalis*, n. sp.; gooseberries attacked by *Hendersonia grossularia*, n. sp.; and buckwheat by *Fusicladium fugopyri*, n. sp. In addition to these new species the following are noted: *Asechyta graminicola* on young rye, *Botrytis cinerea* on leaves and branches of *Prunus cerasus*, *Scolecotrichum melophthorum* on fruits and vines and melons, *Macrosporium parasiticum* on shallots, *Cladochytrium graminis* on oats, and *Helminthosporium gramineum* Rabh., which is said to be identical with *H. teres* Sacc. and *H. gramineum* Eriks., on winter rye.

Notes on plant parasites, G. WAGNER (*Ztschr. Pflanzenkrank., 8 (1898), No. 1, pp. 7-10*).—Notes are given of a number of parasitic fungi. Among them are a number of Uredineae—*Cystopus candidus*, *Plasmopara viticola*, *Brema lactuca*, etc.

Club root of cabbage, B. D. HALSTED (*Amer. Gard., 19 (1898), No. 177, p. 373, fig. 1*).—A brief account is given of experiments made to determine the susceptibility of cabbages to the fungus *Plasmodiophora brassicae*. It is shown that the first three weeks of the life of the plant is the period of greatest susceptibility. On this account seed beds should be looked after very carefully. Lime at the rate of 35 bu. per acre will destroy the fungus in the soil.

Finger and toe (club root) of swedes and turnips (*Gard. Chron., 3. ser., 23 (1898), No. 593, pp. 281, 282*).—As a result of experiments carried on at Reading it is said that quicklime, chalk, or gas lime well mixed with soil will greatly lessen attacks of the disease. Basic slag will to some extent do the same. Swedes or turnips should not be grown for about two years on areas that have received lime.

Mycological notes, C. WEHMER (*Centbl. Bakt. u. Par., 2. Abt., 4 (1898), No. 5, pp. 189-195, pl. 1, fig. 1*).—The author describes a 2-spored form of *Merulius lacrymans*, fermentation of kidney beans, and a *Botrytis* disease of the Chinese primula.

A contribution to the biology of *Exoascus deformans*, VON DERSCHAT (*Landw. Jahrb., 26 (1897), No. 6, pp. 897-901, pl. 1*).

A remarkable gall disease of a North American species of *Abies* in the Berlin Botanic Garden, P. HENNINGS (*Verhandl. Bot. Ver. Pror. Brandenburg, vol. 37, p. 26; abs. in Ztschr. Pflanzenkrank., 8 (1898), No. 1, pp. 39, 40*).—*Pestalozzia tumefaciens*, n. sp. from *Abies nobilis* is described.

Bean canker, G. MASSEE (*Gard. Chron., 3. ser., 23 (1898), No. 594, p. 293, fig. 1*).—A disease of French beans and scarlet runners is figured and described. The cause is said to be *Gloosporium lindemuthianum*.

¹Centbl. Bakt. u. Par., 2. Abt., 3 (1897), Nos. 11-12, pp. 284-291; 15-16, pp. 408-415; 17-18, pp. 478-486. U. S. Dept. Agr., Farmers' Bul. 68, pp. 22 (E. S. R., 9, p. 847, 849).

Studies on potato diseases, C. WEHMER (*Centbl. Bakt. u. Par., 2. Abl., 3 (1897), Nos. 23-24, pp. 646-658; 25-26, pp. 727-743, pls. 2*).—Experimental studies are reported on *Phytophthora* and *Fusarium* diseases. In addition to *Fusarium solani*, the author states that *F. moschatum* and *Spicaria solani* attack the potato and produce symptoms quite like the ordinary *Fusarium* disease.

Investigations concerning a new potato disease, K. SAJO (*Prometheus, 1898, No. 3, pp. 136-140*).

Potato scab and its prevention, HOLLRUNG (*Ztschr. Naturw., 70 (1898), No. 3, pp. 226, 227*).

Experiments in soaking seed potatoes for the prevention of scab, TEICHERT (*Ztschr. Spiritusind., 21 (1898), No. 13, p. 119*).

Experiments in the repression of potato scab, T. PEMY (*Ztschr. Spiritusind., 21 (1898), No. 7, pp. 57-59*).

Phytophthora infestans and the potato rot, E. ROZE (*Bul. Soc. Mycol. France, 14 (1898), No. 2, pp. 58-69*).

A new generic type of Schizomycetes, E. ROZE (*Bul. Soc. Mycol. France, 14 (1898), No. 2, pp. 69-74, pl. 1*).—The author characterizes a new genus of Schizomycetes, to which the name *Chatinella scissipara* is given. It was found in decaying tulip leaves and in the parenchyma of potatoes.

Culture experiments with heterœcious fungi, H. KLEBAHN (*Ztschr. Pflanzenkrank., 8 (1898), No. 1, pp. 11-30, fig. 1*).—The author reports culture experiments with the acidia from *Ribes nigrum*, with *Puccinia caricis*, *P. schroeteriana*, the acidia of orchids, and puccinia of *Phalaris arundinacea*, and the specialization of *Puccinia smilacurum digraphidis*, *P. phragmites*, *P. coronata*, *P. dispersa f. secalis*, *P. cari-historta*, and *P. mentha*.

Recent investigations on the leaf spot of beets, FRANK (*Ztschr. Ver. Rubenz. Ind., 1897, p. 589; abs. in Centbl. Bakt. u. Par., 2. Abl., 3 (1897), No. 25-26, pp. 754, 755*).—The author describes the action of *Cercospora beticola* on beet leaves, and recommends soaking seed for 21 hours in a sort of Bordeaux mixture before planting.

Heterodera radicola on the roots of Corylus avellana, C. CASALI (*Giorn. Vit. e Enol., 5, No. 6*).

Results of field experiments conducted in 1896 with the wet and dry rots of sugar beets, FRANK (*Fühling's Landw. Ztg., 46 (1897), No. 22, pp. 663-672*).

Trials of methods of combating smut in barley, G. GROTENFELT (*Landth. Styr. Meddel., 1897, No. 20, pp. 133-140*).—Trials were made with the Jensen hot-water method, Ceres powder, and the carbon bisulphid method.

Investigations on the root disease of grapevines, J. BEHRENS (*Centbl. Bakt. u. Par., 2. Abl., 3 (1897), Nos. 21-22, pp. 584-589; 23-24, pp. 639-645; 25-26, pp. 743-750*).—Studies are given on *Dematophora necatrix* and allied forms.

On the application of fungicides to grapevines, D. McALPINE (*Ztschr. Pflanzenkrank., 8 (1898), No. 1, p. 11*).—Notes the advantageous use of a 10 per cent solution of sulphuric acid as a wash for the prevention of grape anthracnose.

Effect of temperature on the action of sulphur on grapes (*Ztschr. Pflanzenkrank., 8 (1898), No. 1, pp. 55, 56*).—The best results where sulphur was used to prevent the grape Oidium followed applications made soon after pruning, the temperature being between 25 and 31 C.

Spraying peach trees for peach curl (*Canad. Hort., 21 (1898), No. 6, pp. 236, 237, figs. 2*).—A test of Bordeaux mixture for leaf curl of peaches is noted. Very good results were obtained.

New copper fungicides, L. DEGRULLY (*Prog. Agr. et Vit., 29 (1898), No. 18, pp. 447-447*).—A new fungicide, composed of sulphate of copper 3 kg., lime 1 kg., and desiccated white of egg or dried blood 100 gm., is described. It is claimed for this mixture that it will remain on leaves for months, ordinary rains not washing it off.

On the use of benzin and carbon bisulphid for nematodes, etc., J. RITZEMABOS (*Ztschr. Pflanzenkrank., 8 (1898), No. 1, pp. 42-46, fig. 1*).—A description is given of an injector for the use of these insecticides against nematodes, phylloxera, etc.

Turmeric paper as a test for Bordeaux mixture (*Ztschr. Pflanzenkrankh.*, 8 (1898), No. 1, p. 55).—The use of turmeric paper as a test of the acidity of Bordeaux mixture is recommended.

Fungicides, insecticides, and spraying, J. TROOP (*Indiana Sta. Bul.*, 69, pp. 35-40).—Directions are given for the preparation and application of several of the more common fungicides and insecticides, and a sort of spray calendar is also given in which the directions for prevention of fungus and insect attacks are arranged under the names of the host plants.

ENTOMOLOGY.

Report of the apiarist, R. L. TAYLOR (*Michigan Sta. Rpt.*, 1896, pp. 138-167).—The author discusses the relation of queens to foul brood, various kinds of section comb foundation, the relation of honey to heat, what becomes of the food, preservation of comb and the rendering of wax, wintering, foul brood, swarming, and natural *vs.* artificial swarms.

To determine whether foul brood is carried by queens, a queen from a badly infected colony was transferred to a perfectly healthy one, with the result that no foul brood was developed—an important result bearing on the possibility of spreading the disease in shipping queens.

The general conclusions arrived at from the experiments with foundation is that the quality of the wax has as much if not more to do with the quality of the foundation than the mode of manufacturing. This suggests questions as to whether the undesirable qualities of the wax come from the honey used in producing it or from the excessive boiling, and whether the quality of the wax can be improved.

A water-bath melting vessel devised by the author for extracting candied honey from comb is described in detail. It consists essentially of an outer upright cylinder made of tin, galvanized iron, or copper, and an inner one 2 or 3 in. less in height and 4 to 6 in. less in diameter. The inner vessel stands on metal supports about an inch from the bottom of the other and so that the space between the two is equal on all sides. A spout provided with a wire gauze guard at its inner end runs from the bottom of the inner vessel through the outer and conducts off the honey as fast as it melts. Each can is provided with a cover and the space between is filled with water.

Experiments were made with a view to determining exactly the point at which heat begins to be detrimental to the flavor and color of honey. The question is important from the fact that in the absence of an extractor heat has been employed for extracting. In the first experiment honey was heated in a water bath and samples removed at 145°, 165°, 185°, 200°, and 202° F. The first sample showed no effects whatever, and the differences between the first and second were so slight as to give rise to conflicting decisions. The differences between the second and third were twice as great as between the first and second, and it was noted that in heating to 165° the honey rapidly deteriorated both in flavor and color. The differences between the third and fourth were twice as great as between the second and third and between the fourth and fifth there was evidence of a still more rapid deterioration.

Further experiments with candied honey and honey from different plants revealed the fact that the temperature at which liquefaction occurs varies with the kind of honey. Willow herb and basswood honey became limpid at 145° , while alfalfa honey at that temperature became only slightly limpid and no more transparent than before heating. Samples of alfalfa honey taken at 168° and 180° were dissolved, but not limpid. At 194° the honey was fairly clear, but very much injured in color, having become an amber brown. The flavor, however, was but slightly affected. Samples of willow herb honey were nearly water white at 145° . Basswood samples were a little more golden in color. The change in raising from 145° to 180° was nearly the same with each but many shades lighter than alfalfa honey. The change in flavor at 180° was very slight, at 194° it was noticeable and about the same with each sample. Comparing the two extremes it was noted that less change was found to have taken place in samples heated in tin than in those heated in earthenware, but alfalfa honey was injured least in flavor.

The final conclusion is that the difference between the danger point and the melting point is so great that there is little risk. If the heating is done gradually and as it should be injury scarcely begins before the temperature rises to 170° . The melting of virgin comb with the honey has no effect on color or flavor at any temperature otherwise safe.

An attempt was made to answer the complicated question "What becomes of the feed in feeding for profit, etc.?" The factors which affect this, as the character of the bees and their persistent energy in comb building, etc., the character of the queen, the season, the size and condition of the brood chamber, etc., are considered, and detailed data given of a feeding experiment with three strong colonies of dark hybrid bees for a period of four and a half weeks. The data are discussed at length but no conclusions are drawn.

For the preservation of combs the author has followed four methods: (1) Placing them in hives with strong colonies where the bees might have free access to them; (2) keeping the combs in closed hives in the shop, the hives being placed one above the other, separated by layers of paper and covered with a tight-fitting cover, so that all will keep perfectly dry; (3) hanging the combs up to light and air; and (4) placing the combs in the hives in the bee cellar where the temperature is not sufficiently high for the propagation of the bee moth, provision being made for the exclusion of mice. The first method, where possible, is considered the best and safest although the second has been used with success; the third does well for a season or so, especially if the combs are old and tough, but fresh combs appear to be injuriously affected by light.

In rendering wax the author prefers an open tin vessel 20 in. in height and 24 in. in diameter to the ordinary wax extractor. For combs containing cocoons he uses a rendering tank and prefers a tin

vessel such as is used inside of the ordinary wax extractor and a tin scoop such as is used by grocers. The method of conducting the operation is explained.

Experiments on the relative merits of cellar and out-of-door wintering showed a saving of 9,195 lbs. of stores per colony in cellar as contrasted with out-of-door wintering. Only 3 hives in 120 stored in the cellar were lost from dysentery. For success some stores are necessary, and not less important are temperature and dryness. The author's cellar remained at 45° with a moisture saturation of about 95 per cent; for a drier one it is thought 40° might do.

Concerning foul brood reference is made to the author's report for 1894 (E. S. R., 7, p. 966), to the fasting cure and the drug cure. Where the treatment of colonies must be delayed a mixture of $\frac{1}{4}$ oz. salicylic acid in 1 oz. alcohol and 1 pt. of water added at the rate of 1 pt. to 4 qts. of thin sirup of honey has a decided influence in checking the disease. Fennel (1 part to about 600 parts of the food noted above) is noted, and also burning.

In preventing swarming the author states that he relies on a queen trap so constructed that the queen once in can not return to the hive. In living swarms he has been almost entirely successful in meeting the difficulty of large absconding swarms by giving the swarm a double brood chamber and removing the lower section in two days.

Some experiments were made on the amount of food necessary to produce brood. From the figures obtained the conclusion is drawn that almost exactly 2 $\frac{3}{4}$ lbs. of honey is used up in rearing 1 lb. of brood and that artificial swarms do fully as good work as natural swarms.

The Mexican cotton-boll weevil in 1897, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Circ. 27, 2 ser., pp. 7*).—During 1897 the studies of *Anthonomus grandis* in Texas were continued. The spread of the weevil toward the north and east has been very slow. It is checked by the first frost, and there is some doubt as to whether it will continue beyond the region of volunteer cotton. In rearing experiments undertaken by C. H. T. Townsend at Tobasco, Mexico, where the weevils are common, no parasites were found.

The shortness of the crop in nearly all of the infected region reduced the number of insects so that few were found; but on bottom lands where the cotton was not hurt by the prevailing drought, the weevils were very numerous. They were found to be present at San Antonio, Kenedy, Cuero, Victoria, Beeville, Yoakum, Gonzales, Moravia, Harwood, Shiner, Thompsonville, and Port Lavaca. No great damage is expected for 1898.

In several instances the weevils were found in ginned seed and seed cotton. This fact, which is new, indicates a much greater opportunity for spreading than has hitherto been supposed.

Besides the sharpshooter, formerly reported as being mistaken for this pest, an acorn weevil has been found to produce similar confusion.

A machine for dusting the plants with poison at the rate of 10 acres per hour is noted, and instances cited to show the advantage of domestic fowls as destroyers of the weevil. Otherwise than this the remedies noted are the same as have been given before.

The San José and other scales in Georgia, H. N. STARNES (*Georgia Sta. Bul. 36, pp. 31, figs. 21*).—A popular account of the San José scale and its habits, with special reference to Georgia, together with brief mention of the following scales, more or less common in the State: Florida red scale (*Aspidiotus ficus*), California red scale (*Aonidia aurantii*), English walnut scale (*Aspidiotus juglans-regia*), gloomy scale (*A. leucobricosus*), greedy scale (*A. camellia*), new peach scale (*Diaspis lanatus*), oyster-shell bark louse (*Mytilaspis pomorum*), long or Glover scale (*M. glorerii*), purple scale (*M. citricola*), and the scurfy scale (*Chionaspis furfurus*).

According to the map showing the distribution of the pernicious scale, it has been found in 22 places in 17 counties, and 17 other places are suspected, making 27 counties in all.

A slight variation in the usual list of food plants for the insect is noted for Berrien County, where it has been found on elm, rose, walnut, black gum, corn, sugar cane, and certain weeds.

The introduction of parasitic and predaceous enemies of the scale as allies for its destruction is mentioned with favor. *Spherothilbe coccophila*, the twice-stabbed ladybird (*Chilocorus bifulverus*), and *Pentilia miscella* are noted as most effectual, especially the fungus. Both of the ladybirds as adults attack preferably the older, while the larva attack the younger scales.

Of the three classes of artificial remedies—total destruction, whale-oil soap, and hydrocyanic-acid gas—thought worthy of note, the first is regarded as the best. The last is not thought a suitable remedy for use by small growers or by any than experienced persons. Two applications of whale-oil soap (2 to 2½ lbs. to the gallon, warm) a month apart, or about the middle of November and again about the middle of December, followed in the spring by several applications of kerosene and water (1 to 15) at intervals of two weeks, is recommended.

Late winter or early spring use of the whale-oil soap in the latitude of Georgia is followed by disastrous results. The method is successful only when the buds are thoroughly dormant, i. e., during December. An emulsion of 8 oz. of ivory or whale oil soap, 1 gal. boiling water, and 1 qt. kerosene used in the strength of 1:15, is recommended, but the simpler remedy of kerosene and water in the proportion of 1:15, applied with the Weed Tank, is thought better. The use of pure kerosene is mentioned, but is not at present recommended.

The gas method is treated at some length with special reference to conditions obtaining in Georgia. A tent weighing only 40 lbs. is described, which can be made at a cost of from \$6.50 to \$7. The cost of an outfit that can be kept in constant motion by a gang of 4 men is

placed at \$84, reckoning the cost of a tent at \$7. With such an outfit 192 large 12-foot trees can be treated per night (the best time to work) of 12 hours. Smaller trees would require more tents, but 200 trees per night could be treated. The amount of chemicals required for a 12-foot tree is placed at $4\frac{2}{3}$ fluid oz. of sulphuric acid, 14 of water, and $5\frac{1}{2}$ oz. avoirdupois of 98 per cent potassium cyanid. If the foliage be wet a little more of the chemicals is necessary. This makes a cost per tree of about 4 cts. For treatment of nursery stock a double air-tight chamber is recommended. The time of exposure is placed at at least 45 minutes.

The San José scale and how it may be controlled, J. B. SMITH (*New Jersey Stat. Bul.* 125, pp. 16, fig. 1).—The author here gives a summary of observations and conclusions, the details of which are to appear in the Annual Report of the station for 1897.

At the outset no hope of exterminating the scale in the State is held out, although it may be kept within control. The insect is well established along the Delaware River from Burlington to Camden in gardens, orchards, and hedges, and another colony exists at Jersey City Heights where it is believed to have been carried by birds. The country about Parry within a radius of 10 miles contains many infested places. "The entire section of the State north of the red shale line, running obliquely from Trenton on the Delaware to a point north of Perth Amboy on the Kill von Kull, is yet free, excepting only the spur already mentioned, which includes Jersey City and runs north as far as Hackensack."

Although the insect has existed in the State for ten years the damage sustained is comparatively slight and local. "Practically none save peach trees have been actually killed," and "no single fruit grower has sustained serious injury."

So far as examinations made in 1897 can show there are but two large nurseries within the State having more than a local trade that have traces of the scale, and these are slight. Four, possibly five, nurseries in Burlington, Monmouth, and Atlantic counties with a local trade are infested. The purchaser should demand a guaranty from the grower rather than a certificate.

There can be no doubt as to the destruction to certain fruits, peaches being especially sensitive and following them thin-leaved varieties of plums. Other varieties, and large trees as compared with young trees, suffer less. The latter fact is owing partly to the scale not being able to develop well in the shade, a statement that is particularly true in moist weather.

In conclusion, past experience proves that a single application of any remedy should not be relied upon, but that after a thorough treatment of the infested trees, continual vigilance must be exercised and all omissions promptly attended to with secondary treatment. Little hope is to be had from natural checks save the effect of moist weather, cold, and shade. The California ladybirds introduced have not survived,

and the native parasitic and predaceous forms though increasing in number very rapidly, have thus far not produced any noticeable beneficial effect. *Sphaerostilbe coccophila* has been introduced into two orchards, in one of which it has become well established and may be of service. *Adalia bipunctata* is noted as having been found attacking the larvæ.

Of the various remedies of which the author treats, whale-oil soap (at the usual rate of 2 lbs. to 1 gal. of water or in summer half that strength) and kerosene (applying the finest spray and making the thinnest possible coating and then only when the weather favors evaporation and on dry trees) are especially noted. On some trees the buds are injured by strong solutions of soap, but this effect may be obviated by spraying just before the trees leave out. The application of kerosene, preferably of 150°, though that of 110° has been successfully applied, should be preceded by trimming the trees at least a month before spraying. Summarizing his methods of treatment, he states that badly infested trees should be treated in the winter with either soap or kerosene, according to circumstances, and this followed by one or more summer treatments. Of the two methods, since it is safer, whale-oil soap should be used where it may be effective. "The scales are not hard to kill; the only difficulty is to get all of them."

Relative to certificates and legislation, the author plainly shows that he believes the former more or less worthless and part of an impracticable method. The practice of giving certificates to nurseries has been discontinued for the reason that the certificates are apt to be misused and because of the impossibility of certifying the absolute freedom from the scale. Little sympathy is evinced with the effort to control insects by law, though the author seems to favor a law providing for the destruction of plant pests and for a salaried official whose duties shall be to locate the scale.

The periodical cicada in West Virginia, A. D. HOPKINS (*West Virginia Sta. Bul. 50, pp. 16, pls. 4, figs. 23, map 1*).—More than two-thirds of the entire territory of the State, as learned through circular postal cards sent to all parts of the State, is infested with Brood XV of this insect, which was first recorded for the State May 15, 1795, and has been recorded regularly at 17-year intervals ever since. A large part of the southern portion and some of the eastern portion of the State are uninfested with this brood. Nowhere does the insect seem to occur above an elevation of 3,000 ft.

Where the broods occur the loss occasioned by the oviposition of eggs is very considerable, not only greatly disfiguring twigs but causing them to die and break off. Very often the punctures of the twigs, especially in old and more or less unthrifty trees, never heal over, owing largely to their being immediately attacked by the woolly aphis. Similar injury is also shown to be due to similar wounds produced by the tree cricket, which are kept from healing by the same aphid.

On the northern border of the infested district the adults appear nearly two weeks later than those along the southern border. As between the lowest and the highest altitudes there seems to be a difference of appearance of about four weeks, which corresponds with the difference in average summer temperature to be found between the localities. Between the northern and southern boundaries of the region this difference is 3.5°, between the lower and higher altitude 10°. Each degree of difference in the mean summer temperature appears to make about three and one-half days of difference in the time of the first general appearance of the cicada. Whether this seeming rule will also apply to other broods remains to be determined. The character of the weather at the time of emergence is important. If it be cold the insects become chilled, crawl slowly, and become an easy prey to birds, poultry, and other predatory enemies.

The author notes finding an isolated specimen in May, 1895, which, although appearing two years earlier than the normal time, he feels certain belongs to Brood XV. None were seen or heard during the spring of the next year, but during the fall of 1896 several specimens were heard. This appears to be the second record of an occurrence of this cicada in the fall of the year.

At Morgantown, West Virginia, the first cicadas were heard May 27 and 30. Copulation commenced about June 9, oviposition about the 13th. The leaves and wounded twigs began to wilt four days later. The insects began disappearing the last week of June and none were heard after July 4. Eggs on twigs began hatching August 20 and all the young during the following week seemed to have emerged.

The eight broods and nine swarms occurring in the State are XVII (1898), XX (1900), XXI (1901), XXII (1902), V (1905), VIII (1906), XI (1910), and XV (1914). It will be noted that they occur in periods of 2, 1, 1, 3, 1, 4, and 4 years. The author gives brief notes, historical and otherwise, on each of these broods and swarms, and then notes the sections of the State where several broods overlap. Of the eight broods in point of numbers XXI, XXII, V, VIII, and XV are most to be feared, the last being the largest swarm.

Among natural enemies mentioned, aside from numerous predatory and parasitic insects not definitely named and a contagious disease often of an epidemic nature, are English sparrows, hogs, poultry, and squirrels.

Some common injurious insects of western Nevada, F. H. HILLMAN (*Nevada Sta. Bul. 36*, pp. IX+39).—A popular descriptive list of 39 insects, including a brief key for their identification. The habits of each are brought out and in most cases the most practical remedies. Some of the more important points are the probable occurrence of two distinct broods of *Euranesa antiopa* in Nevada, the first about June, the second in August or September. It has fed only on the elm and willow. *Vanessa cardui* does not feed on hollyhock in that region.

The apple aphid (*Aphis mali*) seems to confine its attack mostly to young trees, and is attacked by a disease probably of bacterial nature that destroys large numbers during the latter part of the summer. The bodies shrivel up, turning to a dark-brown color, and remain on the leaves. The woolly aphid (*Schizoneura lanigera*) is thoroughly established and is especially favored by the character of the Nevada climate. In many orchards uninfected trees are the exception. *Mytilaspis pomorum* has not yet been found in the State on fruits, but has been taken from the Lombardy poplar in Carson City. Other insects treated are as follows: Flat-headed apple-tree borer (*Chrysobothris femorata*), pear and cherry slug (*Selandria cerasi*), imported cabbage butterfly (*Pieris rapa*), mourning-cloak butterfly (*Eucanessa antiopa*), hollyhock butterfly (*Vanessa caryae*), hop-vine butterfly (*Grapta satyrus*), tomato worm (*Phlegethontius cecus*), poplar hawk moth (*Marumba modesta*), locust-tree carpenter moth (*Prionoxystus robiniae*), codling moth (*Carpocapsa pomonella*), ash-gray pinion (*Lithophane antennata*), currant-stem borers (*Sesia tipuliformis*, *Chrysobothris femorata*), cabbage plusia (*Plusia brassicae*), corn-ear worm (*Heliothis armiger*), zebra caterpillar (*Mamestra picta*), cutworms, diamond-back moth (*Plutella cruciferarum*), snowy tree cricket (*Ecanthus niveus*), plant lice (*Aphis* spp.), apple-leaf louse (*A. mali*), woolly aphid (*Schizoneura lanigera*), cabbage louse (*A. brassicae*), plum-leaf louse (*A. prunifolii*), rose-plant louse (*Aphis* sp. ?), currant-leaf louse (*A. ribis*), elm-leaf louse (*Aphis* sp. ?), cottonwood-leaf louse (*Aphis* sp. ?), poplar-leaf gall louse (*Pemphigus* sp. ?), willow-stem louse (*Lachnus* sp. ?), San José scale (*Aspidiotus perniciosus*), English-walnut scale (*Aspidiotus juglans-regiae*), oyster-shell bark louse (*Mytilaspis pomorum*), *Lecanium ribis*, cottony maple scale (*Paltrinaria innumerabilis*), imported elm-bark louse (*Gossyparia ulmi*), rose-leaf hopper (*Typhlocyba rosa*), buffalo tree hopper (*Ceresa bubalus*), red spider (*Tetranychus telarius*).

Insect injuries to Ontario crops in 1896, J. FLETCHER (*Rpt. Ontario Ent. Soc. 1896*, pp. 58-69, figs. 15).—Cereals were attacked by the wheat-stem maggot (*Meromyza americana*), American frit fly (*Oscinis variabilis*), Hessian fly (*Cecidomyia destructor*), wheat midge (*Diplosis tritici*), grain aphid (*Siphonophora arenae*), and army worm (*Leucania unipuncta*).

Fodder crops were attacked by three common species of grasshoppers—the red-legged locust, two-striped locust, and the lesser migratory locust. In some cases they were reported to have disappeared suddenly. This was doubtless due to the increase of their natural enemies—*Empusa grylli*, tachina flies, and locust mites (*Trombidium locustarum*), which seem to be the most efficient workers in keeping down the numbers of grasshoppers. This mite is discussed somewhat at length. Another parasite of grasshoppers noted is the hair snake or hair worm. Other insects noted are gray blister beetle (*Macrobasis unicolor*), clover-root borer (*Hylesinus trifolii*), clover-seed

midge (*Cecidomyia leguminicola*), white grub (*Lachnosterna*, sp.), clover cutworm (*Mamestra trifolii*), zebra caterpillar (*Mamestra picta*), two hymenopterous insects (*Trichogramma pretiosa* and *Telonomus* sp.), red-backed cutworm (*Caruades ochrogaster*), black army worm (*Noctua fennica*), striped cucumber beetle (*Diabrotica vittata*), squash bug (*Anasa tristis*), apple curculio (*Anthonomus quadrigibbus*), apple maggot (*Trypeta pomonella*), cigar case bearer (*Coleophora fletcherella*), pear slug (*Selandria cerasi*), phylloxera (*Phylloxera vastatrix*), grape thrip (*Erythronera vitis*), strawberry-leaf roller (*Phoropteris comptana*), red spider (*Tetranychus* sp.), and black peach aphid (*Aphis persicae-niger*).

Root crops were attacked by the clover cutworm (*Mamestra trifolii*), zebra caterpillar (*Mamestra picta*), and white grub (*Laenosterna* sp.). As parasites on the zebra caterpillar *Trichogramma pretiosa* and a new species of *Telonomus* are mentioned.

Vegetables were attacked by the red-backed cutworm (*Caruades ochrogaster*), striped cucumber beetle (*Diabrotica vittata*), and squash bug (*Anasa tristis*): fruits, by the apple curculio (*Anthonomus quadrigibbus*), apple maggot (*Trypeta pomonella*), (which has not hitherto been known to attack fruit trees in Ontario), cigar case bearer (*Coleophora fletcherella*), pear slug (*Selandria cerasi*), phylloxera (*Phylloxera vastatrix*), grape thrip (*Erythronera vitis*), strawberry-leaf roller (*Phoropteris comptana*) (the two broods of which did considerable injury around Picton in Prince Edward County), a red spider (*Tetranychus* sp.), and black peach aphid (*Aphis persicae-niger*).

Injurious insects, etc. (*Jour. Bd. Agr. [London], 4 (1898), 4, pp. 468-480, figs. 6*).—The stem eelworm (*Tylenchus devastatrix*), orchid beetle (*Xyleborus perforans*), pine aphid (*Lachnus pini*), and fruit-tree beetle (*Scolytus rugulosus*) are discussed. Injuries caused by the first appear to be extending, wheat, oats, hops, clover, and onions being the principal objects of attack, although attacks on the first are not very common. In the hops other species (*Heterodera schachtii*) are also found. Other plants noted as attacked are rye, beans, the grasses (*Anthoxanthum odoratum*, *Holcus lanatus*, and *Poa annua*), and various weeds, viz, daisy, shepherd's purse, spurry, buttercup, cornflower, sow thistle, etc. The worms which are briefly described are exceedingly hardy, larvæ having been revived after being dried for two and one-half years. This power of enduring drought greatly increases the chances of distribution. Cold nearly suspends animation. A scarcity of food causes the larvæ to migrate upward to the surface where life is suspended in the dry soil.

The usual remedy of deep plowing, burning of refuse, allowing the land to lie fallow, and the use of fertilizers are recommended, the mixture thought best being 3 cwt. sulphate of potash and 1 cwt. sulphate of ammonia, although 1 cwt. sulphate of iron, 1 cwt. sulphate of potash, and 1 cwt. sulphate of ammonia was nearly as good. For imported clover 4 cwt. dissolved bones and 2 cwt. sulphate potash per acre was

good. Another mixture was composed of 4 cwt. of kainit, 2 cwt. sulphate iron, and 3 cwt. superphosphate. For oats 5 cwt. kainit, $1\frac{1}{2}$ cwt. sulphate of ammonia, and 1 cwt. sulphate of iron, also 2 cwt. sulphate of potash, 2 cwt. sulphate of iron, 3 cwt. nitrate of soda, and 1 cwt. sulphate of potash are said to have given good results. For onions the best mixture is thought to be sulphate of potash, sulphate of iron, and nitrate of soda, mixed at the rate of 2 cwt. each per acre.

Natural history of the genus *Chrysopa*, Leach, M. LURIE (*Abs. in Zool. Centbl.*, 5 (1898), No. 10, pp. 335, 336).—The original is in Russian. The author arrives at the conclusion that the laying of eggs by the lace-winged fly at the end of a long stalk is for protection rather than for accelerating the development of the egg. The period of the egg state is constant for each species. In the larva of *Chrysopa ventralis* a dorsal shield serves as a protection against parasitic Hymenoptera. The larvæ of *C. septempunctata* molts on the fourth and seventh day after leaving the egg, and probably also a third time. When the time for pupation is near the larva first spins a sort of cover with a thread from an anal gland, then lies on its back and spins a web beneath it. When the cocoon has become thick the larva rolls itself up and ceases spinning.

The substance used in the formation of the cocoon, the author states, is derived from the upper fringe of Malpighian vessels. The cell nuclei of these undergo changes during the process of secreting. Formerly round, they become oblong, and at the completion of the process they assume a peculiar branched form. In *C. vulgaris* there is a double generation. There is in the vicinity of Warsaw, however, but one. The pupal state lasts six months, the larval over five, the egg state several days, and the number of eggs reaches sixty.

Besides the general biology the author also studied the anatomy of the insect. The mandibles recall those of the ant-lion larva.

How flowers attract insects, P. KNUTH (*Bot. Centbl.*, 14 (1898), No. 2, pp. 39-46; *abs. in Zool. Centbl.*, 5 (1898), No. 10, pp. 331, 332).—The author considers Plateau's conclusions (*E. S. R.*, 9, p. 158) on this subject as imperfect. The odor of flowers is thought to attract until the insect is within 1 or 2 meters, when sight is thought to be the chief guide.

Catalogue of the Odonata of Ohio, D. S. KELLICOTT (*Jour. Cincinnati Soc. Nat. Hist.*, 19 (1897), No. 2, pp. 66-71).—Thirteen species are noted here.

Orthopterological notes. I, On the development of the wings in the genus *Nemobius*; II, Parthenogenesis and parasitism in *Bacillus gallicus*, J. DOMINIQUE (*Bul. Soc. Sci. Nat. Ouest France*, 7 (1897), pp. 265-271; *abs. in Zool. Centbl.*, 5 (1898), No. 7, p. 230).—The eggs of the second generation of *Bacillus gallicus* in the cases investigated developed but few larvæ and all of these turned out to be females.

Three new species of Chrysopidæ, N. BANKS (*Proc. Ent. Soc. Washington*, 4 (1897), No. 2, pp. 173-175).—*Chrysopa sabulosa*, *C. fraternæ*, and *Leucochrysa americana*. The first and second from Fort Collins, Colorado, and the third from Auburn, Alabama.

The species of *Pepsis* inhabiting America north of Mexico, W. J. FOX (*Proc. Ent. Soc. Washington*, 4 (1897), No. 2, pp. 140-148).—Four new species, *Pepsis circularis*, *P. lucasii*, *P. inermis*, and *P. bogueti* are described.

Entomology of the oak, A. T. GILLANDERS (*Trans. Manchester Micros. Soc.*, 1897, pp. 78-88; *abs. in Jour. Roy. Micros. Soc.* [London], 1898, No. 3, p. 74).

A preliminary review of the North American Delphacidæ. E. P. VAN DUZEE (*Buffalo Soc. Nat. Sci. Bul.*, 5, No. 5, pp. 225-261).—A taxonomic paper mentioning old and describing new species.

Studies on insect larvæ. I, On the knowledge of *Phalacroceria replicata*, S. BENGTSSON (*Lunds Universitets Årsskr.*, 33 (1897), pp. 118, pls. 4; *abs. in Zool. Centbl.*, 5 (1898), No. 8, pp. 268-272).—The entire development of this water larva runs through the course of a year. The egg-state lasts from 8 to 12 days, the pupal period 7 to 8. There have been 8 moltings determined with certainty and very probably there are 9, if not 10. The old skin always bursts longitudinally along the back. Though the larva has a true head, it forms a link between the well-marked head of the encephalic dipteran larvæ with the "jaw cap" of Tipulid and other dipteran larvæ. Three thoracic and nine abdominal segments are to be distinguished.

Hymenoptera, Neuroptera, Pseudoneuroptera, Orthoptera, and Rhingota of Italy. A. GRIFFINI (*Imenotteri, Neurotteri, Pseudoneurotteri, Orthotteri, e Rincoti Italiani*. Milan: U. Hoepli, 1897, pp. XV+677, figs. 223).—In treating of each genus an example is figured and treated morphobiologically. For a preliminary study of insects the volumes are very useful, although they can not give a complete scientific conception of Italian fauna, and since the authorities for the species are not mentioned the latter can not be placed with certainty.

On two Lepidoptera injurious to sugar cane introduced into the Mascareignes Islands, E. BORDAGE (*Compt. Rend. Acad. Sci. Paris*, 125 (1897), No. 25, pp. 1109-1112).—The history of the introduction and synonymy of *Diatraea striatalis* and *Sesamia nonagrioides*.

Considerations on the study of melliferous plants, A. SOŃSIEDSKY (*Rev. Internat. Apicult.*, 20 (1898), No. 4, pp. 68-71).—The meagerness of any popular literature on the subject of melliferous plants is noted, yet the subject is well worth study. A well-known Russian apiculturist, Zonbareff, in a work on apiculture states that one can not give any one plant absolute preference, for the same plant on different soil and under different conditions of climate varies in the quantity and quality of nectar yielded. Plants considered to be of secondary value in one country or locality in others may take first rank. *Melissa officinalis* is indigenous to a moist climate and loses its melliferous qualities in a dry one.

Bee keeping and its regulation in the Middle Ages and in recent times, M. WAGNER (*Inaug. Diss.*, Munich, 1897, pp. 89, pl. 1, maps 3).—This deals with bee keeping in its historical and legal aspects, going back to the time of Charlemagne.

Something new relative to the development of gadfly larvæ of cattle, SCHNEIDEMÜHL (*Centbl. Bakt. u. Par.*, 1, Abt., 22 (1898), No. 24-25, pp. 752-760).—Besides making historical mention of several *Gestrada*, the pathological significance of *Gestrus oris* is noted and more at length the life history of *Hypoderma bovis*. Contrary to the belief hitherto current, the larvæ of the latter insect passes the greater portion of its larval existence inside the animal. The eggs enter the alimentary canal partly with the fodder and partly from licking the skin.

Notes on the season of 1896, J. A. MOFFAT (*Rpt. Ontario Ent. Soc.*, 1896, pp. 76-79, figs. 2).—The climatic conditions in the southern portion of Ontario are noted as having been very diverse within short distances, but the Colorado beetle and the imported cabbage butterfly seem to flourish under all conditions. *Hadena arctica*, which were very abundant in 1895, were exceptionally rare this year. The army worm (*Leucania uipuncta*) was very destructive near Hamilton, Ontario. A Harpalus was found preying upon it. The lime-tree winter moth (*Hybernia tilicaria*) was very abundant around London, Ontario, in the early part of October. Other insects noted are *Papilio marcellus*, *P. philenor*, *P. cresphontes*, *Erchus odora*, the Carolina sphinx (*Macrosila carolina*), *Cisthene uifascia*, *Aspila rirescens*, and *Hyphantria cunea*, the last being very prevalent.

Report on injurious insects in Finland, 1895 and 1896, E. REUTER (*Lundbr. Skriv. Meddel.*, 1897, No. 21, pp. 53).

Injurious and useful insects of Java, I, J. C. KONIGSBERGER (*Meded. S'Lands Plantentuin*, 22 (1898), p. 53).

Some injurious insects, G. C. DAVIS (*Michigan Sta. Rpt. 1896*, pp. 375-401, figs. 21).—A reprint of Bulletin 132 of the station (E. S. R., 8, p. 241).

Pests of house and ornamental plants, G. C. DAVIS (*Michigan Sta. Spec. Bul. 2*, pp. 45, figs. 34).—This is a popular bulletin giving notes as to insecticides and on the following insects, with suggestions as to treatment: Red spider (*Tetranychus telarius*), myriapods, isopods, slugs and snails, cel worms (*Heterodera radicola*), thrips (*Colothrips trifasciata*), yellow-lined plant bug (*Pacilocapsus lineatus*), tarnished plant bug (*Lygus pratensis*), hollyhoek bug (*Orthotylus delicatus*), chrysanthemum net wings (*Corythuca ciliata* and *C. gossypii*), water-lily leaf hopper (*Megamelus darisi*), plant lice, aleyrodes, mealy bugs, scale insects, cutworms, rosebud moths, white grubs, wireworms, Fuller's rose beetle (*Aramigus fulleri*), rose slugs (*Monostegeia rosa*), and ants.

Some beetles occurring upon beech, W. H. HARRINGTON (*Rpt. Ontario Ent. Soc.*, 1896, pp. 69-75, figs. 7).—The following insects are mentioned, most of which are briefly described and some of which were bred: *Hyperelis nyssaria*, pretty little easemaker (*Incurvaria acerifoliella*), large horntail (*Tremex columba*), *Trogosita corticalis*, *Grynocharis 4-lineata*, *Corymbites cruciatus*, *Dicercia divaricata*, *Chrysobothris femoralis*, *C. sersignata*, *Agrilus bilineatus*, *A. interruptus*, *Brachys viruginosa*, *B. uroa*, *Thanoerlus sanguineus*, *Eucrada humeralis*, *Ptilinus ruficornis*, *Platycerus quereus*, *P. depressus*, *Ceruchus piceus*, *Dichelonycha elongata*, *Osmoderma scabra*, *Parandra brunnea*, *Smodicum cucujiforme*, *Dryobius scurfasciata*, *Nyctrochus quadrimaculatus*, *Cyrtophorus verrucosus*, *Centrodera decolorata*, *Tortus schaumii*, *Anthophilax attenuatus*, *Leptura subhamata*, *Goes pulcrulentus*, *Acanthoderes quadrigibbus*, *Leptostylus macula*, *Hoplosia nubila*, *Pelecotoma flavipes*, *Pandeletcus hilaris*, *Ithycerus norboracensis*, *Cryptorhynchus bisignatus*, *Acoptus suturalis*, *Phloeophagus apionoides*, *P. minor*, *Stenoscelis brevis*, *Monarthrum fasciatum*, and *Nyctobius obesus*.

Contributions to the biology of some bark beetles of Austria and bordering countries, J. KNOTEK (*Oesterr. Vierteljahrsschr. für Forstwesen.*, 1897, No. 2, pp. 136-161, figs. 6; *abs. in Zool. Centbl.*, 5 (1898), No. 7, pp. 236, 237).—In the first publication the author enumerates 57 species, giving notes on local distribution and on food plants. As new species *Hylesinus henscheli* and *Scolytus aceris* are mentioned, the first of which is similar to *H. crenatus*. The latter is closely related to *S. intricatus* of Ratzeberg, which feeds on several maples. The appearance of its work recalls that of *S. geoffroyi* of Goetze. Several observations are also made on the two little known species *Phloeosinus bicolor* of Brull (*Aubei* of Perris), and *Scolytus larvis* of Chapuis.

In the second paper additions are made to the list just noted.

The bark beetles of Bosnia and Herzegovina, J. KNOTEK (*Wissen Mitteil aus Bosnien u. d. Hercegorina*, 2 (1894), pp. 7, pls. 2; *abs. in Zool. Centbl.*, 5 (1898), No. 7, pp. 236, 237).

Lepidopterous pests of the meadow and the lawn, T. W. FYLES (*Rpt. Ontario Ent. Soc.*, 1896, pp. 97-104, figs. 5).—This is mostly a descriptive list with notes on Satyridæ, Hesperidæ, Ctenuchidæ, Arctiidæ, Noctuidæ, and Crambidæ affecting Gramineæ. A table for the identification of a species of Crambids is given.

The principal insect enemies of the grape, C. L. MARLATT (*U. S. Dept. Agr., Farmers' Bul. 70*, pp. 23, figs. 12).—This is a reprint from the Yearbook of this Department for 1895 (E. S. R., 9, p. 803).

The butterflies of the eastern provinces of Canada, C. J. S. BETHUNE (*Rpt. Ontario Ent. Soc.*, 1896, pp. 106-110, figs. 9).—This is a list of 114 butterflies with notes as to the locality where taken and their relative abundance. *Grapta interrogationis*, usually rare in the Province of Quebec, was found in great abundance feeding on

elm in the vicinity of Montreal. The variety *G. interrogationis umbrosa* was abundant at Port Hope in May and June and *G. interrogationis fabricii* was taken July 29 and as late as November 10, 1896. *Argynnis atlantis* is noted as having extended its range and is now found at Orillia. *Colias easonia* appeared suddenly in very considerable numbers in several localities during the summer of 1896.

Contributions to the biology and morphology of the Aphidæ. I, On the biology of some species of Aphides, A. MORDVILKO (*Horæ Soc. Ent. Ross. [St. Petersburg]*, 31, pp. 253-313, ill.: *abs. in Zool. Centbl.*, 5 (1898), No. 7, pp. 231-234).—This work comprises a number of recent observations on the biology of several aphides and forms a continuation of an earlier communication. The morphological peculiarities and the biological phenomena are considered in connection with surrounding conditions of life.

Germany's exclusion of American fruits, J. B. SMITH (*North American Review*, 66 (1898), No. 4, pp. 460-465).—The reason for the exclusion of American fruits by the German Government is explained as due to a misunderstanding of the nature and means of dispersal possessed by the San José scale. So far as known, the insect has never spread from fruit to tree. It can only crawl before it becomes fixed to its host plant, but if infested fruit should be brought sufficiently close to a plant there is no doubt that the scale could be spread in this way.

The San José scale, L. R. TAFT (*Michigan Sta. Rpt.* 1896, pp. 124, 125).—Briefly discusses the scale and its treatment, and notes the scales that may be mistaken for it.

The black peach aphid, L. R. TAFT (*Michigan Sta. Rpt.* 1896, pp. 125-127).—Numerous complaints are noted. The insect was particularly injurious to young trees, and was distributed by ants and other insects. Tobacco water, salt, nitrate of soda, kerosene emulsion, bisulphid of carbon, and wood ashes are noted as remedies.

The box-elder plant bug, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Circ.* 28, 2. ser., pp. 3, fig. 1).—The general appearance, method of work, distribution, habits, and remedies against *Leptocoris trivittatus* are very briefly discussed.

Mites injurious to plants, VON SCHLECHTENDAL (*Ztschr. Naturw. [Jena]*, 70 (1898), No. 3, pp. 228, 229).

The pests and blights of the tea plant, G. WATT (*Calcutta: Supt. Govt. Printing, India, 1898*, pp. III+467+XLVII, figs. 11).—A report of investigations made in Assam and Kangra. The culture of the tea plant is discussed with special reference to diseases and insect pests.

The spruce gall louse, W. BRODIE (*Ontario Dept. Agr. Spec. Bul., May, 1898*, pp. 2, pl. 1).—A popular circular on *Chermes abietis*.

Report of the consulting entomologist, G. C. DAVIS (*Michigan Sta. Rpt.* 1896, pp. 135-138).—*Lygus pratensis*, mushroom insects (*Tyroglyphus phylloxera*, *Sciaria vulgaris*, *Aphodius granarius*, and *Ips fasciatus*), little red cherry beetle (*Adimonia caricollis*), false chinch bug (*Nyssius augustatus*), grasshoppers, and the Hessian fly (*Cecidomyia destructor*) are mentioned. Ten or more common varieties of wheat at the college farm were severely injured by the last insect.

Spraying—why and how, L. R. TAFT (*Michigan Sta. Spec. Bul.* 4, pp. 13-19, fig. 1).—A popular discussion of the subject, noting formulas for insecticides, fungicides, and apparatus.

Instructions in spraying (*Ontario Dept. Agr. Spec. Bul., Mar., 1898*, pp. 16, figs. 13).—Directions are given for the preparation of fungicides and insecticides and the treatment of different host plants for the prevention of attacks of injurious fungi and insects.

White arsenic as a substitute for Paris green, L. R. TAFT (*Michigan Sta. Rpt.* 1896, pp. 119, 120).—Arsenic is found to be much less expensive than Paris green and fully as efficient if not more so. One pound is placed in 2 gal. water with an equal weight of freshly slacked lime and boiled for 30 to 40 minutes. The resulting insoluble calcium arsenate is sufficient for 400 gal. water. At this strength it can be employed on all kinds of fruit along with Bordeaux mixture. It costs about one-fifth as much as Paris green.

On some parasites of Coccidæ, with descriptions of two new genera of Aphelininæ, L. O. HOWARD (*Proc. Ent. Soc. Washington*, 1 (1898), No. 2, pp. 133-138, figs. 3).—Besides describing two new species, the representatives of two new genera, namely, *Archenomus bicolor* and *Azotus marshali*, notes on distribution are given. Prior to 1891 *Aspidiotiphagus citrinus* was unknown. In this country since then it has been taken from 18 species of scale insects and from many localities in the United States, from Grenada, British West Indies; Portici, Italy; Punduloya, Kandy, Ceylon; Hongkong and Amoy, China; Tamsui, Formosa; Yokohama, Japan; Newlands, Cape Colony; Adelaide, South Australia; and Honolulu, Hawaii. A similar wide distribution has also been found for *Prosopalla aurantii*, *Aphelinus fuscipennis*, *A. acylaspidis*, and *A. diaspidis*. *Archenophagus chinaspidis* has also an almost universal distribution. As a new locality for *A. diaspidis*, San Luis, Mexico, is noted, and for *A. fuscipennis*, Natal.

A new Swedish egg parasite, C. AURIVILLIUS (*Ent. Tidskr.*, 18 (1897); *abs. in Zool. Centbl.*, 5 (1898), No. 9, p. 295).—The author describes and figures a pteromalid of the subfamily Trichogrammatinae, for which he erects the genus *Oophthora*. The form seems to be closely related to *Trichogramma* of Westwood. It differs from that form in its longer, nearly cylindrical abdomen. The author thinks that *Trichogramma pretiosa* and *T. minuta* of Riley may possibly be properly considered as belonging to the new genus. To the species he gives the name *Oseublidis*. The specimens emerge from the eggs of *Scablis lutoria*. The male appears to be dimorphic. Some appear without wings, others with wings. The latter closely resemble the female.

Notes on parasitic Hymenoptera, with descriptions of some new species, G. DIMMOCK and W. H. ASHMEAD (*Proc. Ent. Soc. Washington*, 4 (1898), No. 2, pp. 148-171).—Brief notes by Dimmock on 70 species, and a description by Ashmead of 29 new species belonging to the genera as follows (the figures denoting the number of species of the genus): *Telonomus*, *Allotria*, *Encyrtus*, *Habrocytus*, *Elachistus*, *Cratotechus*, *Eulophus*, *Apanteles* (6), *Protopanteles* (2), *Microplitis*, *Aphidius*, *Hypothenantes*, *Ischnoscopus*, *Mesochorus*, *Neocryma*, *Sychnoportus*, *Phæogenes*, *Acrobela*, and *Asphragis*.

Parasitic worms on cultivated plants, E. HENNING (*Landtmann*, 9 (1898), No. 19, pp. 299-303, ill.).

Development of *Platygaster*, N. KULAGIN (*Ztschr. Wiss. Zool.*, 63 (1897), pp. 195-235, pls. 2; *abs. in Jour. Roy. Micros. Soc.* [London], 1898, No. 3, p. 73).—This parasite of *Cecidomyia*, it is learned, occurs in a large number of dipterous, hemipterous, and hymenopterous larvae. The larva of *Platygaster* lives on the fat body of the host and pupates at the same time with it. The occurrence of one parasite in the same host is not usually fatal; the occurrence of two is.

Repressive measures against enemies of field crops, B. FRANK (*Kampfbuch gegen die Schädlinge unserer Feldfrüchte*. Berlin: Parey, 1897, pp. 308, pls. 20, figs. 46; *abs. in Zool. Centbl.*, 5 (1898), No. 5, p. 157).—This work will doubtless be of considerable use to many zoologists. It is written in a popular style, showing how to recognize the animal and vegetable enemies of vegetables; treats of life histories, habits, etc. The colored plates represent the eggs, larvae, and the character of ravages. The book is divided into five parts, treating of the injuries to conifers, leguminous plants, potatoes, corn, and beets.

FOODS—ANIMAL PRODUCTION.

Food preservatives, H. LEFFMANN (*Pennsylvania Dept. Agr. Rpt.* 1897, I, pp. 535-548).—A number of food preservatives are described. The effect upon the digestibility of starch of the following substances was tested: Saccharin, beta-naphthol, formalin, artificial benzoic acid,

natural benzoic acid, artificial sodium benzoate, sodium benzoate, boroglycid, sodium carbonate, salicylic acid, citric acid, boric acid and borax (alone and together), tartaric acid, sodium fluorid, and sodium silico-fluorid. The digestive ferments employed were malt diastase, taka-diastase, pancreatic extract, peptenzym, and carase. A few qualitative experiments on the effect of preservatives on peptic digestion were made but are not reported in detail.

The general conclusions follow:

"Salicylic acid in all its forms, i. e., natural, crude commercial, and refined commercial, is distinctly antagonistic to most enzymes, especially those that convert starch. There seems to be no reason to believe that the natural form of the acid will be less objectionable than the artificial in this respect, even if its price does not exclude its use.

"Sodium benzoate is without appreciable interfering action, and as its preservative action is undoubted and its disagreeable taste will prevent its liberal use in any food article, it seems to be well adapted for general use.

"Boric acid and borax show but little interfering action with either starch or proteid digestion. Boroglycid seems also to possess but little interfering action.

"Beta-naphthol interferes with the action of malt-diastase, but not seriously with taka-diastase or pancreatic extract. It interferes very decidedly with peptic and pancreatic digestion of proteids.

"Sodium fluorid has but little interfering action with starch transformations, but sodium silico-fluorid interferes decidedly with pancreatic extract.

"Sodium acid sulphite is without retarding effect.

"Salicylic acid does not interfere seriously with proteid digestion."

Analyses of feeding stuffs, E. F. LADD (*North Dakota Sta. Bul. 32, p. 277*).—Analyses are reported of corn silage, prairie hay, Hungarian hay, and fodder from corn planted at different distances. The results of the latter analyses are as follows:

Composition of fodder from corn planted at different distances.

	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
In drills $3\frac{1}{2}$ by 2 ft.	9.38	2.00	63.85	19.84	4.93
In drills 6 in. apart.	8.14	2.61	57.66	23.22	8.37
In rows $3\frac{1}{2}$ by 16 in.	8.20	2.48	63.39	20.96	4.97
In drills 30 in. in drill.	8.67	2.98	58.49	23.98	5.88

In the author's opinion the best fodder was obtained when the plants had room for full development.

Nutrition investigations at the University of Tennessee in 1896 and 1897, C. E. WAIT (*U. S. Dept. Agr., Office of Experiment Stations Bul. 53, pp. 46*).—The investigations include studies of the composition of a side of Tennessee beef, a side of Tennessee mutton, and the meat of chickens; two dietary studies with mechanics' families, and two with students' clubs; and a number of experiments with man on the digestibility of combinations of two food materials and of a mixed diet. In connection with the latter experiments the balance of income and outgo of nitrogen was usually determined also.

The studies of the composition of meat and the dietary studies were similar to those carried on previously under the auspices of the Department of Agriculture at the University of Tennessee and other institutions. The results of the dietary studies are briefly shown in the following table:

Results of dietary studies—cost and composition of food eaten per man per day.

	Cost.	Protein.	Fat.	Carbo- hydrates.	Fuel value.
	<i>Cents.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Calories.</i>
Mechanic's family	11	97	206	426	4,060
Do	17	95	127	305	2,820
Students' club	17	123	142	433	3,595
Do	14	66	155	451	3,560

The digestion experiments were made with healthy subjects. Two, and sometimes three or four, subjects received the same kinds of food, the quantities varying to suit the individuals. The food, urine, and feces were analyzed according to the usual methods. The results of the experiments are summarized in the following table:

Summary of the twenty-one digestion experiments, showing coefficients of digestibility found.

Ex- peri- ment No.	Sub- ject.	Kind of food and weights per day (in grams).	Total or- ganic matter.	Pro- tein.	Fat.	Car- bo- hy- drates.	Ash.	Avail- able- en- ergy.
			<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>

Nutrition investigations in Pittsburg, Pennsylvania, 1894-1896, ISABEL BEVIER (*U. S. Dept. Agr., Office of Experiment Stations Bul. 52, pp. 48*).—These investigations include six dietary studies of families living in Pittsburg, a study of the variation in cost and composition of bread in Pennsylvania, and a bakery experiment.

The dietary studies (pp. 7-43).—The studies were made with the families of a lawyer, two mill workmen, a boiler tender, a decorator, and a glass blower.

Tables are given showing the kind and amount of food purchased, wasted, and eaten, and its cost, composition, and fuel value. The average results are summarized as follows:

Results of dietary studies—cost and composition of food eaten per man per day.

Subjects.	Cost.	Protein.	Fat.	Carbohy- drates.	Fuel value.
	<i>Cents.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Calories.</i>
Professional man's family (No. 43).....	21	91	145	380	3,280
Mill workman's family (No. 128).....	13	85	104	307	2,575
Mill workman's family (No. 129).....	9	77	90	314	2,440
Boiler tender's family (No. 189).....	22	147	173	683	5,010
House decorator's family (No. 190).....	20	112	144	368	3,305
Glass blower's family (No. 191).....	16	94	121	385	3,085

The dietaries are discussed and compared with the results of similar studies made elsewhere,

In carrying on these investigations special attention was given to the amounts expended for food accessories—i. e., tea, coffee, condiments, flavorings, etc. It was found that, aside from tea and coffee, there was a comparatively small expenditure for such materials.

"In dietary No. 128, \$21.52 was expended for food materials and \$1.20 for food accessories. While this sum was not large, it should be remembered that as compared with the standards this family had insufficient nourishment. The conclusion seems warranted that they could have advantageously expended this sum for flour, bread, potatoes, beans, or the cheaper cuts of meat. This sum expended for flour at the price actually paid per pound for that purchased would have added 8 gm. of protein and 260 calories of energy per man per day to the diet. In the same way in dietary No. 129 the protein might have been increased 12 gm. per man per day and the fuel value over 100 calories.

"While tea and coffee are stimulating and refreshing as beverages, they are comparatively expensive and furnish little if any nutriment. Either cocoa, whole milk, or skim milk would furnish considerable nutriment besides being useful as a beverage. Of these materials the skim milk would furnish the largest food return for the sum expended."

Variations in the cost and composition of bread (pp. 43-46).—Ten samples of bread purchased in the open market were analyzed and the fuel value calculated and determined by the bomb calorimeter. The weight of the loaves and the cost per pound were also recorded. The results are compared with the results of a similar investigation made in New Jersey.¹

"There is a much greater variation in the price per pound of bread than in its chemical composition, and, moreover, the variations in the latter bear little or no relation to those in the former. The lowest price per pound was 2 $\frac{3}{4}$ cts.; the highest, 7 $\frac{1}{2}$; the average, 3 $\frac{3}{4}$ cts. The protein varied more than either the water or the carbohydrates, the lowest proportion being 9.2 per cent; the highest, 15.4 per cent; the average, 10.8 per cent."

The variations noted in fat and mineral content of the different samples were small and are regarded as unimportant. Variations in the water content were attributed to different methods of baking, while variations in protein and carbohydrate content were regarded as due to differences in the flour and other materials employed.

"The variations in cost are dependent almost entirely upon the baker. Different makes of bread sell at different prices per pound, while the nutritive value may be essentially the same in all cases. . . . As a rule, in the New Jersey samples, the larger the loaf the greater the cost per pound. The study in Pittsburg was too limited in extent to allow many definite deductions. The size of the loaf, apparently, had no direct bearing upon the price of the bread per pound. This depended rather upon the brand or trade name given by the maker."

Bakery experiment (pp. 46-48).—In the experiments made in New Jersey, mentioned above, baked bread was found to contain less fat than the materials from which it was made. To study this point further an experiment was conducted in a bakery in Pittsburg in which the materials and the bread made from them were analyzed. The results of the New Jersey investigation were confirmed.

¹ U. S. Dept. Agr., Office of Experiment Stations Bul. 35 (E. S. R., 9, p. 78).

"It would seem that either the fat is rendered partially insoluble in ether during the process of baking or that it has been volatilized. The fact that there is a very considerable loss in the fuel value of the materials in the bread as compared with that of the raw ingredients before baking indicates that the latter is the true explanation, for if the fats had simply been rendered nonextractable their heat of combustion would probably have remained unchanged and there would be no such pronounced loss of heat values as is actually the case."

The cost of the raw materials and of the bread made from them is also discussed. It was found "that raw materials worth \$1.24 when made into bread sold for \$2.60, or an increase of 110 per cent over the original cost."

A comparison of Utah feeding stuffs, L. FOSTER and L. A. MERRILL (*Utah Sta. Bul.* 51, pp. 119-140).—Experiments were made with nine lots of steers to test a number of Utah feeding stuffs and to compare indoor and outdoor feeding. Each lot contained 4 steers, with the exception of lot 6, which contained only 2. They were mostly 2-year-olds, of Shorthorn and Devon breed, with a few Aberdeen Angus and Holsteins.

The test, which began January 1, 1897, covered 90 days and was divided into two periods of 39 and 51 days, respectively. In most cases the steers were fed coarse fodder only during the first period of the test. Lot 1 was fed alfalfa, with barley in addition during the second period; lots 2 and 7, alfalfa and straw, with barley and bran during both periods; lots 3 and 8, corn fodder, with bran in addition in the second period; lot 4, timothy hay, with bran and pea meal in the second period; lot 5, alfalfa and shredded corn fodder 1:1, with the addition of bran and barley in the second period; lot 6, shredded corn fodder and roots, with the addition of bran in the second period; and lot 9, alfalfa with barley and bran in the first period and alfalfa and barley in the second.

Lots 1 to 6 were kept in the barn and were given some exercise each day in an open yard, and lots 7 to 9 were kept in yards with open sheds.

The financial statement is based on the following prices of feeding stuffs per ton: Alfalfa, \$4; shredded corn fodder, \$5; timothy hay, \$6; bran, \$10; barley, \$16; peas, \$20; roots, \$3.50; and straw, \$1.

The results for each lot are tabulated.

The principal conclusions reached were as follows:

"During the first period the gains were higher and less dry matter was required per pound of gain. The results add proof to the often repeated proposition that as the animal gains in flesh it requires a constant increase in the quantity of food for each additional pound of gain.

"For this single trial, feeding a grain ration with alfalfa during the preliminary period did not prove profitable.

"Roots had the effect of increasing the appetite without giving proportionate additional gain. From this and previous trials it may be inferred that roots can not be economically used in feeding simply for the nutrients they contain, being less profitable when so fed than the ordinary dry fodders.

"The results of three trials show that straw may be profitably used as a part ration in connection with alfalfa and grain. The experiment detailed herein shows, too,

that open-yard feeding gives a better appetite for the straw and enables the steer to make more profitable use of it.

"With the average Utah steer and our mild, dry winters, the best results, both in rate of gain and economic use of foods, are obtained by giving the animal the freedom of the corral and a good open shed that he may occupy at will.

"Timothy hay made the lowest and most unprofitable gain. Its relatively higher market price than alfalfa debars it from profitable use in cattle feeding.

"The average yield of the corn-culture experiments and the favorable results from the feeding of shredded corn fodder indicate that corn may be safely reckoned as one of the feeder's resources in Utah.

"In rate of gain when fed without grain, alfalfa stood the highest and timothy the lowest of the lots fed indoors.

"The quantity of dry matter required for a pound of gain was highest for alfalfa and lowest for corn fodder, with timothy ranking second highest.

"Comparing the proportion of digestible dry matter in the different foods, they stand as follows: Barley, 100; pea meal, 89; bran, 70; corn fodder, 68; alfalfa, 64; timothy, 63; straw, 51.

"In cost per pound of digestible dry matter, at the market prices quoted, pea meal was the highest and wheat straw the lowest."

Corn fodder is discussed at some length and the yields of corn per acre for several years at the station are quoted. In the dry atmosphere of Utah "corn fodder may be so thoroughly field cured that there is no danger of heating when shredded and stored where it is protected from the weather."

Wheat and corn as food for pigs, C. S. PLUMB and W. B. ANDERSON (*Indiana Sta. Bul.* 67, pp. 61-70).—Tests of the value of wheat and corn alone and in combination were made with 16 Chester White pigs, divided into four equal lots. Each lot consisted of 3 barrows and 1 sow. Lot 1 was fed corn; lot 2 dry wheat; lot 3 corn and wheat 1:1, and lot 4 wheat soaked in cold water. In addition all the lots were fed daily 10 to 12 lbs. of separator skim milk. After a preliminary period of 8 days, the test began January 9 and extended over 105 days. Each lot was confined in a separate inclosure of about 350 sq. ft., with a small pen attached.

To learn something of the time at which pigs may be most economically fattened, during two-thirds of the trial they were not fed all the grain they could have assimilated. During the latter part of the trial they were fed to their full capacity. The corn used was a yellow dent variety grown on the station farm. The greater portion of the wheat was an interior grade which was purchased. Before feeding it was run through a fanning-mill. Chemical analysis did not show that it differed in composition from the wheat grown at the station. The financial statement is based on corn at 40 cts., wheat at \$1.25, and skim milk at 8 cts. per hundred.

In general the pigs remained in good health throughout the test. One pig in lot 1 was sick for a day, and one in lot 4 was affected with scours. It was noticed that the pigs fed soaked wheat were somewhat inclined to looseness of the bowels though not seriously so. The pigs were weighed each week, and the data of the experiments are recorded in full in tabular form.

The following table shows the principal results of the trial:

Results of feeding wheat and corn to pigs.

	Food consumed.		Weight at beginning.	Average daily gain per pig.	Grain consumed per pound of gain.	Cost per pound of gain.
	Grain.	Skim milk.				
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Cents.</i>
Lot 1 (corn).....	1,588.75	11.46	184.75	1.16	3.25	1.49
Lot 2 (dry wheat).....	1,591.00	11.46	173.75	1.02	3.67	4.57
Lot 3 (corn and wheat).....	1,591.00	11.46	175.50	1.12	3.59	2.97
Lot 4 (soaked wheat).....	1,591.00	11.46	189.25	1.05	3.36	4.70

In order to learn the proportion of grain which passed through the pigs undigested the whole grains in three samples (weighing 5 oz. each) from the feces of each lot of pigs were counted. On an average the 5 oz. of manure from the lot fed corn contained 7 whole grains; from the lot fed dry wheat 1,167 grains; from the lot fed corn and wheat 685 kernels of corn and 12 of wheat, and from the lot fed soaked wheat 1,003 grains. The conclusion is drawn that wheat should be crushed or broken before feeding. A trial showed that 4 per cent of the wheat kernels from the feces of the lot fed dry wheat germinated. None of the undigested grains from the lot fed soaked wheat germinated.

A test was made of the strength of the bones of the pigs in each lot.

“Generally speaking, the result of these tests shows that the bones of the corn-fed lot crushed most readily, while those of the soaked-wheat lot crushed least readily. The principal feature of interest was that the bones of the corn-fed pigs seemed appreciably softer than those of the other three lots.”

The organs and flesh of the different lots were weighed and examined, but no marked differences were observed.

Montana swine feeding. F. BEACH (*Montana Sta. Bul. 14, pp. 19-33, pls. 2*).—A test was made with pigs to learn the value of alfalfa and of stubble fields for pasture and to compare barley with different mixtures of barley, wheat, and peas. On August 22, 9 brood sows (averaging 272.3 lbs.) and 44 pigs (averaging 57.1 lbs.) were turned on an alfalfa pasture of $4\frac{1}{2}$ acres. The pigs were from 2 to 5 months old. They received 1 lb. of cracked barley per head daily, and were fed in a pen which was so arranged that they could pass in and out. The sows could not enter the pen and received no food in addition to the pasture. At the end of 6 weeks the sows on an average had gained 5 lbs. in weight. In 2 weeks the pigs made an average gain of 4.5 lbs. per week. Three pigs (boars) were then removed. In the 5 weeks following the remaining pigs made an average gain of 0.42 lb. per head daily. They were then turned into barley, wheat, and pea stubble fields of 18 acres, 10.44 acres, and 10.73 acres, respectively. They were not fed grain in addition to what they could find in the fields, except on stormy days, the grain thus fed amounting to 24.1 lbs. in 5 weeks. During this time the pigs made a gain of 22.8 lbs. per head, or 17.5 lbs. deducting the amount

which it was calculated they gained from the grain fed during stormy weather. On the supposition that 4.5 lbs. of grain are required to produce a pound of pork the 41 pigs gathered 3,238.75 lbs. of grain which otherwise would have been lost. The harvesting had been done in the usual manner, and in the author's opinion the amount of peas and grain remaining in the fields did not exceed that in the stubble fields on the average farm.

Seven brood sows were afterwards pastured during the winter on the station stubble fields, which included a 24-acre oat field in addition to those mentioned above. They were given no food in addition to what they could gather, except kitchen slops and a small grain ration on stormy days. "The sows frequently rooted down through 6 in. of snow and found sufficient grain to keep them in good condition throughout the entire winter."

November 21, 38 pigs from the lot which had been pastured on stubble fields, and 11 others, farrowed about the same time, were divided into one lot of 13 and three lots of 12 each. The pigs averaged about 120 lbs. in weight. They were pure and grade Poland Chinas and grade Chester Whites. Lot 1 was fed barley; lot 2, barley and wheat, 1:1; lot 3, barley and peas, 1:1; and lot 4, barley, peas, and wheat, 1:1:1. The barley and wheat were fed ground and dry, as it was found that when fed whole some grain passed through the pigs undigested. The peas were fed whole and were well masticated. The test was divided into three periods of 32, 21, and 23 days. One pig was dropped from lot 3 at the end of the first period.

The wheat was rated at \$1, barley at 65 cts., and peas at 70.7 cts. per hundred pounds. The food consumed and gains in weight made during the different periods are recorded. At the close of the experiment the pigs were sold at 3½ cents per pound live weight.

During the first period the average daily gains for the four lots were 1.62, 1.65, 1.62, and 1.75 lbs., respectively; and the food consumed per pound of gain, 4.89, 4.64, 4.53, and 4.36 lbs. During the second period the average daily gains were 1.68, 1.63, 1.69, and 1.71 lbs.; and the food consumed per pound of gain, 5.05, 5.06, 5.01, and 4.82 lbs., respectively. During the third period the average daily gains were 1.21, 1.22, 1.15, and 1.27 lbs., the amounts of food consumed per pound of gain being 6.71, 6.45, 6.51, and 5.90 lbs.

Among the conclusions reached were the following:

"Pigs make the greatest gains and consume less grain per pound of gain before they reach 200 to 210 lbs. in weight.

"The quality of pork produced from wheat, barley, and peas in the various combinations used is firm and well adapted for the production of hams and bacon, the fat and lean of the meat being well distributed.

"Pigs fed on barley or barley and wheat at present market prices will pay for all food consumed when pork is 3½ cents a pound.

"The pea combined with grain is well adapted to the wants of the growing animal, and will give the greatest gains on the smallest amount of feed."

Some essentials of beef production, C. F. CURTISS (*U. S. Dept. Agr., Farmers' Bul. 71, pp. 24, figs. 17*).—The author discusses the most desirable type of cattle for fattening, mentions the characteristics of this type, and illustrates the use of the score card. Diagrams are given showing the method of cutting beef. The bulletin as a whole is based largely on experiments at the Iowa Station.

According to the author, animals suitable for fattening, "though representing different breeds, present that compactness of form, thickness, and substance, together with superior finish and quality, coupled with an inherent aptitude to lay on flesh thickly and evenly, that always characterizes the beef animal of outstanding merit." For fattening the prime requisite is general form. This point is discussed at some length.

The author points out that gains in weight are not a sufficient index of the gains in value in fattening animals. Thus, animals of different breeds may make approximately the same gains in the same period of time, yet in one case the gains may consist of fat accumulated around the viscera while the flesh remains lean. In another case the fat may be well distributed throughout the carcass, making juicy meat. These differences are very clearly brought out by the block test. The fact is noted that in recent years there has been a marked change in the kind of beef preferred. A very large overfat steer is no longer as desirable as the more compact animal of prime quality and medium size—that is, younger animals are more desirable than older ones.

"It is a well established principle in animal nutrition that young animals make more economical gains than older ones, and that the amount of food required for a given gain increases as the animal advances toward maturity." The economy of gain at different ages is discussed. In regions where coarse fodders and pasturage are abundant it may be desirable to extend the fattening period.

"In the great feeding section within what is known as the 'corn belt' the conditions are such as to favor the liberal policy of feeding from first to last, and under these conditions early maturity may be attained by a generous use of the ordinary feeding stuffs throughout the entire growing and fattening period, quite as well or even better than by too extensive use of the more concentrated and expensive grain feeds. That is to say, early maturity may be largely accomplished by the liberal use of the cheaper feeds of the farm, combined with a suitable grain ration, which may be quite moderate except in the finishing period. The modern feeder must combine the advantages of economy of production resulting from early maturity, and the excellence and enhanced value of the finished product that can only come from the right kind of stock well handled. This implies good breeding and continuous good feeding. These requirements are no longer merely subservient, but practically imperative."

Digestion experiments, J. A. WIDTSOE (*Utah Sta. Bul. 54, pp. 141-151*).—Experiments on the digestibility of shredded corn fodder, alfalfa hay, timothy hay, and a mixture of 71.5 per cent bran and 28.5 per cent shorts were made with steers. Two steers of common native stock were used and the ordinary methods were followed. The steers

were fed the rations tested for at least a month before the beginning of the experiments, which covered from 7 to 10 days. The coarse fodders studied were fed alone. Corn fodder was fed with the wheat bran and shorts, and its calculated digestibility was deducted in determining the digestibility of the grain.

The coefficients of digestibility are shown in the following table:

Coefficients of digestibility of various feeding stuffs.

	Dry matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Shredded corn fodder:

Average.....	57.90	45.45	38.04	63.33	58.35	25.88
Bran and shorts: Steer 1.....	58.14	75.75	44.98	64.25	18.33	7.50

The results are briefly discussed and compared with similar results obtained elsewhere.

Poultry, C. D. SMITH (*Michigan Sta. Rpt. 1896, pp. 109, 110*).—A brief report is given of the poultry kept at the station. Wheat was compared with corn as the principal ration for grown chickens. In addition to green food 2.8 lbs. of wheat or 2.77 lbs. of corn was required for a pound of gain. The cost of a pound of gain increased very rapidly as the chickens approached 5 lbs. in weight. A record was kept of the food consumed and eggs laid by three lots of 30 hens of the same age and breed having the same feeding and care. In six months lot 1 laid 2,232 eggs; lot 2, 2,357 eggs, and lot 3, 2,295 eggs. A record was also kept of the temperature of poultry houses with different areas of glass. The temperature was found to vary but little.

The nutritive value of Italian paste made wholly or in part of Indian corn, T. JACOANGELI and A. BONANNI (*Bol. Not. Agr., 19 (1897), No. 29, pp. 434-448*).—The authors discuss the food of the poor classes in Italy, calling attention to the fact that Indian corn is the principal food of the poor people in a considerable portion of the southern part of the Italian Peninsula and adjacent islands. It has usually been eaten in the form of polenta; that is, a porridge seasoned with fat, cheese, or other material. Many investigations have been made on the possibility of making satisfactory Italian pastes—i. e., macaroni, etc.—from corn alone or mixed with wheat. The authors report a number of experiments on the digestibility and comparative value of polenta and Italian pastes. In the first test the food consisted exclusively of polenta (corn-meal porridge) seasoned with a little lard, preserved tomatoes, and cheese. In the other tests the food consisted entirely of Italian pastes made of corn,

wheat, or a mixture of the two, which were eaten in the form of a thick soup. In accordance with the usual custom the food was taken in two meals—one at 10 in the morning and the other at 4 in the afternoon. Water was the only beverage used, the quantity consumed varying little from day to day.

The coefficients of digestibility and the income and outgo of nitrogen during the different tests are shown in the following table:

Results of experiments with polenta and Italian pastes.

Food consumed per day.	Coefficients of digestibility.				Nitrogen—			
	Dry matter.	Protein.	Fat.	Carbo-hydrates.	In food.	In urine.	In feces.	Gain.
Corn-meal porridge 2,912 gm.	<i>Per ct.</i> 91.50	<i>Per ct.</i> 75.6	<i>Per ct.</i> 84.99	<i>Per ct.</i> 94.66	<i>Grams.</i> 11.03	<i>Grams.</i> 7.81	<i>Grams.</i> 2.69	<i>Grams.</i> 0.53
Soup from corn-meal paste, 3,459 gm.	94.77	89.81	85.98	96.31	13.35	19.51	1.36	1.48
Soup from paste $\frac{3}{4}$ corn meal, $\frac{1}{4}$ low-gr. de flour, 3,117 gm.	94.91	90.54	86.79	96.49	14.01	10.97	1.37	1.67
Soup from paste of best wheat flour, 2,859 gm.	96.09	91.22	87.56	97.46	13.45	10.63	1.19	1.63
Soup from paste of $\frac{3}{4}$ corn meal and $\frac{1}{4}$ low-grade flour, 3,077 gm.	94.78	90.33	85.76	96.31	13.33	10.44	1.29	1.60
Soup from paste of low-grade flour, 2,814 gm.	94.79	90.76	86.19	96.31	14.39	11.67	1.33	1.39

The authors discuss the experiments at considerable length. The following general conclusions were reached:

The Italian pastes made from corn meal are much better assimilated than the porridge. In this respect they are nearly equal to the pastes made from the finest quality of wheat flour. The corn-meal pastes furnish a food product in which digestible protein may be obtained at a less cost than in corn-meal porridge or wheat pastes of different qualities. It is believed that such pastes will prove of the utmost importance in dietaries of people of limited income.

The composition and food value of bread purchased in Lisbon in March, 1892. A. DE SEABRA (*Sar la composition et la valeur alimentaire du pain du marché de Lisbonne, aus mois de mars, 1892. Lisbon: Libanio da Silva, 1897, pp. 14*).—The composition and digestibility of a number of kinds of Portuguese bread are reported. Few details of methods followed are given.

"Chocolate" oats, BALLAND (*Compt. Rend. Acad. Sci. Paris, 126 (1898), No. 18, pp. 1289-1291*).—The name "chocolate" oats is applied to oats which have acquired a brownish color from exposure to rain and sun. The composition of such oats and oats of normal color, grown near Mostaganem, is reported.

The value of the kola nut as a part of a ration, L. BERNEGAU (*Die Bedeutung der Kola-Nuss als Beifutterstoff. Altona: 1897; abs. in Bot. Centbl., 73 (1898), No. 12, p. 460*).—A brief account is given of a feeding experiment with the kola nut in Madagascar. The author also reports investigations with horses. The addition of kola feeding stuff to the ration enabled the horses, in his opinion, to perform more severe labor, while at the same time they did not lose weight if the ration was diminished.

Milk as food (*U. S. Dept. Agr., Farmers' Bul. 74, pp. 39, charts 2*).—This is a popular bulletin, discussing the composition, chemistry, variations, nutritive value, and digestibility of milk and the comparative value of skim milk, cream, and buttermilk. The use of milk in combination with other foods is treated of and a number of daily menus containing large and small amounts of milk are given.

Vinegar, E. F. LADD (*North Dakota Sta. Bul. 32, pp. 278, 279*).—A number of samples of so-called pure cider vinegar were examined. In the author's opinion there is much deception practiced, and the term "pure cider vinegar" does not give a fair indication of the product sold under that name in many cases.

Coloring matter in confections, C. B. COCHRAN (*Pennsylvania Dept. Agr. Rpt. 1897, I, pp. 529-535*).—The author examined 21 samples of candy. Of these 16 were

found to be colored with coal-tar colors. In addition to sucrose, which was found in all the specimens, nearly all the candies contained glucose and many starch and dextrose. No excess of mineral matter or other injurious substance, unless the coal-tar colors be regarded as injurious, was found.

A number of artificial digestion experiments are reported on the effect produced by the coal-tar colors, auramin, Bismarck brown, rhodamin, rose bengal, eosin, acid magenta, and methyl violet. The effect of all these coloring matters upon peptic digestion was studied and the effect of rhodamin, methyl violet, and eosin upon pancreatic digestion. In all the tests 0.125 gm. of the coloring was used with 100 cc. of the digestive ferment solution and 1 gm. of beef.

"In every case the presence of a coal-tar color exerted some retarding influence on digestion. The results indicate that eosin and acid magenta interfere decidedly with peptic digestion and that methyl violet produces just as decided interference with pancreatic digestion. . . .

"It therefore seems to me safe to assert that any substance so totally foreign to food as a coal-tar dye, which can be shown, when used in reasonable amounts, to retard artificial digestion, must rest under grave suspicion."

Handbook of subsistence stores (*U. S. War Dept., Office Commissary General of Subsistence, Doc. 19, pp. 199, fig. 1*).—The foods, condiments, and other materials included under the head of subsistence stores for the United States Army are described. In many cases processes of manufacture are given, as well as statistical and other information of a useful character. Among other points the effect of freezing and of heat on canned goods is discussed.

Subsistence manual (*U. S. War Dept., Office Commissary General of Subsistence, Doc. 21, pp. 57*).—In addition to matter concerning the purchase and transportation of subsistence stores, information is given concerning the rations, food materials, and care of food and other stores supplied by the Subsistence Department of the United States Army.

Silage, C. D. SMITH (*Michigan Sta. Rpt. 1896, pp. 107-109*).—The yield per acre and composition of corn cultivated in different ways and of sorghum raised for silage is given. The sorghum silage kept well. Owing to the woody stems it contained a high percentage of crude fiber which was not relished by the stock.

The velvet bean (*Florida Agr., 25 (1898), No. 13, p. 176*).—Notes are given on the value of the velvet bean for green manuring and on the use of the green beans as food. The latter shelled and cooked caused serious although not fatal illness.

Feeding value of potatoes, C. D. SMITH (*Michigan Sta. Rpt. 1896, p. 107*).—This is a brief summary of work reported in Bulletin 149 of the station (*E. S. R., 9, p. 1081*).

On the influence of muscular exercise, sweating, and massage on metabolism, J. C. DUNLOP, D. N. PATON, R. STOCKMAN, and I. MACCADAM (*Jour. Physiol., 22 (1897), No. 1-2, pp. 69-92*).—Five experiments were made with men. In three the effect of excessive muscular exercise was studied, in one the effect of sweating, and in one the effect of massage. The food, urine, and feces were analyzed and the income and outgo of nitrogen was determined.

From the experiments the following conclusions were reached: Sweating and massage does not produce any marked influence on metabolism.

"Excessive muscular work causes an increased catabolism of protein, this being shown by the increased excretions of nitrogen and of sulphur in the urine. The protein consumed is muscle protein, shown by the increased nitrogen and sulphur excretions not being accompanied by increased excretions of uric acid, extractive nitrogen, and phosphorus, muscle being a tissue poor in nucleo proteins which produce these waste products. If the subject who performs excessive muscular work be in poor training, this consumption of muscle protein is accompanied by the consumption of the protein of other tissues which contain nucleo proteins, as shown by the increased excretions of uric acid, extractive nitrogen, and phosphorus.

There may here be a withdrawal of protein from other structures to effect repair in muscles, similar to the transference of material seen in starvation, the protein portion being retained, while the nucleic acid portion is excreted. . . .

"Our conclusions show the importance of two points long known to athletes and others doing excessive muscular work. The one is the importance of proper training, for by it an abstraction of proteid matter from tissues other than muscle can be avoided; the other is the importance of their being a sufficiency of protein in the diet to compensate for the loss which occurs. An abundance of protein in the diet of an athlete has other functions to fulfill beside this. It is required during training for building up the energy liberating mechanism—the protoplasm of muscle—and it is also required after work to repair that mechanism. The benefits of training are well known in other ways, such as preparing the heart for suddenly increased duty and limiting the after fatigue effects."

Muscular exertion and gaseous exchange, L. SCHNYDER (*Inaug. Diss., Bern. Munich: R. Oldenbourg, 1896, pp. 53, figs. 2*).—A number of experiments with man in which the respiratory quotient was determined are reported. Some of the subjects were in health, others were convalescent. The principal conclusions reached were that muscular work increases metabolism, as shown by the increased production of carbon dioxide. The increase, however, is diminished if the labor is continued until it becomes habitual. In the same way an improvement in the general physical condition—that is, a gain in strength—lowers the increased metabolism.

Investigation on the source of muscular energy, K. KAISER (*Ztschr. Biol., 36, No. 3, pp. 358-419, pl. 1*).—A number of experiments were made with the muscles of frogs. The subject of muscular energy is discussed from a mathematical standpoint.

A further study of the influence of alcohol and alcoholic drinks upon digestion, with special reference to secretion, R. H. CHITTENDEN, L. B. MENDEL, and H. C. JACKSON (*Amer. Jour. Physiol., 1 (1898), No. 2, pp. 164-209*).—Supplementing previous work on the effect of alcohol and alcoholic drinks upon the processes of digestion (*E. S. R., 7, p. 971*), the authors made a number of experiments with dogs. Some of the more important conclusions follow: The presence of strong alcohol or an alcoholic beverage in the mouth has a direct stimulating effect, causing for a short time an increase in the flow of saliva. Not only is the volume of saliva increased, but also the amount of organic and inorganic constituents. This effect is not peculiar to alcohol, but is common to dilute acid (vinegar), ether vapor, etc., and is analogous to the effect produced by electrically exciting the nerves of the salivary glands. It was not found that alcoholic fluids absorbed from the stomach had any influence upon the amount or composition of the saliva. Thus, when alcohol was introduced directly into the stomach of dogs by injection through the stomach wall no effect upon the salivary secretion was observed. "Hence, so far as our results go, alcohol and alcoholic fluids are without any specific effect upon the secretion of saliva except to produce a transitory stimulation of secretion while in the mouth cavity."

Alcohol or alcoholic fluids increase very greatly the flow of gastric juice and its content of acid and total solids. That is, it contains more acid, more solid matter, and more combined hydrochloric acid than the ordinary secretion. It is also strongly proteolytic. An increase in the secretion of gastric juice is produced not only by alcoholic fluids in the stomach, but also indirectly by alcohol absorbed from the intestine, even if the latter is ligated.

"If these results are considered in connection with our previous observations upon the influence of alcohol and alcoholic drinks upon the purely chemical processes of gastric digestion, it is seen that side by side with the greater or lesser retardation of digestive proteolysis caused by alcoholic beverages there occurs an increased flow of gastric juice rich in acid and of unquestionable digestive power. The two effects may thus normally counterbalance each other, though it is evident that modifying conditions may readily retard or stimulate the processes of the stomach according to

circumstances. Foremost among the latter is the rapid disappearance of alcohol from the alimentary canal. . . . This point has been very carefully and thoroughly tested by numerous experiments on healthy dogs with gastric fistulae, using proteid test meals, with the result that certainly in the stomach of dogs digestion is not retarded in any pronounced degree under the influence of alcohol or alcoholic fluids. Of hastened digestion the results obtained gave little or no suggestion, and we must therefore conclude that the two diverse factors above referred to more or less counterbalance each other, so that gastric digestion in the broadest sense of the term is not markedly varied under the influence of alcohol or alcoholic fluids. . . . In view of the rapid disappearance of alcohol from the intestinal tract it is plain that alcoholic fluids can not have much, if any, direct influence upon the secretion of either pancreatic or intestinal juice."

Note on the digestion of starch in the stomach, W. G. A. ROBERTSON (*Proc. Roy. Soc. Edinburgh*, 21 (1895-1897), pp. 96-104).—A number of experiments were made with diseased and healthy men on the digestibility of starch by ptyalin, the digestion of starch in the stomach, and the combined effect on starch of gastric and salivary digestion.

Does the Stutzer method of artificial digestion furnish reliable data for deductions concerning the digestibility of protein? A. SANOTSKI (*Zap. Novo-Alexandri Inst. Selsk. Khoz. i Lyesor.* 10 (1897), No. 2, pp. 1-17).—The author criticises Stutzer's method of artificial digestion and believes too sweeping deductions should not be drawn.

On the value of asparagin in feeding herbivora, O. KELLNER (*Verhandl. Gesell. Deut. Naturf. u. Aerzte Braunschweig*, 68 (1897), pp. 110-112).—A brief report of experiments previously noted (E. S. R., 9, p. 1079).

The poisons developed in foods during fermentation or putrefaction, with two illustrative cases, F. T. ASCHMAN (*Pennsylvania Dept. Agr. Rpt. 1897*, I, pp. 727-736).—A general discussion of the subject.

On a Soudanese grass, DYBOUSKI (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 10, pp. 771, 772).—The author gives the composition of the seed of *Paspalum longiflorum* and compares it with other well-known cereals (E. S. R., 10, p. 79). This grain is used to a considerable extent for food.

Beets and the feeding of dairy cows; value of forage beets and dried and ensiled cossettes, L. GRANDEAU (*Jour. Agr. Prat.*, 62 (1898), No. 10, p. 345).

On the origin of polled cattle, E. O. AREXANDER (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897*, I, pp. 468, 469; II, App. 13, pp. 13, map 1).

On the influence of the temperature of the stable on the productive capacity of farm animals, E. O. AREXANDER (*Landtmannen*, 9 (1898), Nos. 11, pp. 171-173; 12, 189-191).

Fattening lambs, F. B. MUMFORD (*Michigan Sta. Rpt. 1896*, pp. 267-285).—A reprint of Bulletin 128 of the station (E. S. R., 7, p. 887).

Lupines for pigs, HORNUNG (*Deut. Landw. Presse*, 25 (1898), No. 36, p. 394).—A brief account, condensed from *Mittheilungen der Vereinigung deutscher Schweinzüchter*, is given of feeding lupines to pigs. The test reported, which was of 107 days duration, was made with 2 pigs. They were fed daily 1.5 lbs. peas, 1 lb. beans, 1 lb. barley, 1 lb. coarse wheat bran, 3 lbs. potatoes (poor quality), 0.5 lb. lupines, 0.125 lb. peanut meal and molasses, 0.25 lb. molasses with a little milk and buttermilk. The pigs weighed at the beginning 332 lbs. and gained 85.5 lbs. per pig at a cost of 9.5 cts. per pound.

The feeding and watering of horses, D. HUTCHEON (*Jour. Jamaica Agr. Soc.*, 2 (1898), No. 5, p. 172).—A general article.

Advantages and disadvantages of modern methods of poultry culture, S. CUSHMAN (*Agr. Massachusetts, 1897*, pp. 95-115).—A paper presented at the public winter meeting of the Massachusetts Board of Agriculture at Taunton, in 1897, with a discussion.

DAIRY FARMING—DAIRYING.

Some points in the physiological chemistry and coagulation of milk. D. F. HARRIS (*Proc. Roy. Soc. Edinburgh*, 21 (1895-1897), pp. 72-89).—The author studied the physical-chemical condition of caseinogen in milk, the chemistry of the coagulation of caseinogen, the chemistry of casein, the digestion of milk, etc. He uses the term caseinogen to mean casein as it exists naturally in the milk, before it is coagulated. With reference to the caseinogen he concludes that—

“Caseinogen is not, in the ordinary acceptation, in solution in milk plasma. It is in the most intimate association with the fat; in all probability the particles consist of fat in direct ratio and of caseinogen in indirect ratio to their bulk. In this sense caseinogen is ‘particulate.’”

“The arguments that caseinogen is present as an envelope are still entitled to respect; but there is some evidence pointing to this proteid being interstitially associated with the fat.

“Both the clots and precipitates in milk and in ‘pure’ caseinogen are more or less cohesive agglutinations of the preexisting particles; there is no trace of fibrous structure.

“The so-called ‘pure solutions’ of caseinogen are suspensions of particles upon whose presence depends their coagulability, in which respect they resemble diluted milk or concentrated whey. Their pressure-filtrates contain no proteid.”

The author’s experiments confirm Ringer’s view that the coagulation of casein is a twofold process, the first stage being the conversion of caseinogen by rennet into a soluble form of casein, which he calls procasein; and the second stage, the precipitation or solidification of this procasein into a more or less cohesive clot or curd (casein).

By analyses of acetic-acid whey and rennet whey the author shows that “there is some chemical difference between the precipitation of caseinogen by an acid and the clotting of it by rennet—a difference able to be expressed, at least, in terms of the union of calcic phosphate. Some call this clot a caseate of calcium. Normally in milk it may be so.”

The effect of various salts on the curdling of milk was studied, and the curdling of milk from which the lime had been removed by precipitation with potassium oxalate and centrifugal force, using decalcified rennet.

“Only the soluble salts of calcium, barium, and strontium can precipitate procasein. They are concerned only with the second stage of clotting. . . .

“One factor in the inhibition of clotting by certain potassium salts is the high alkalinity.

“The absence of lime is a more powerful inhibitant than the presence of potash.”

The experiments with artificial digestion of milk which had received different treatment lead to the following statements:

“My experiments with milk mixed with water or with CaH_2O_2 , in order to render it more digestible, as it is alleged, tend to show that this property is entirely due to the greater laxity of the clot which forms when the solid particles of milk are, from any cause, separated from one another. Evidently the power of rennin for binding

particle to particle is weakened when it has to act through a greater distance upon these particles. None of these clots in diluted milk has the absolute laxity of the pancreatic clot in milk. . . .

"I have confirmed Budin's observations as to the superior digestibility of milk heated to 100° C. . . .

"Milk boils at 101.5° C. I have corroborated the statement that fresh milk yields a blue color with tincture of guaiac, while boiled milk does not.

"I am unable to substantiate the statement of authors that boiled milk is far more difficult to coagulate than unboiled milk' . . .

"Authors state that this 'difficulty' is due to some of the calcic phosphate having become insoluble. I can find none of it upon prolonged centrifugalization."

Some investigations concerning separator slime, BARTHEL (*Nord. Mejeri Tidn.*, 12 (1897), Nos. 12, pp. 495, 496; 43, p. 507, ill.).—The author discusses the formation and composition of separator slime, and shows that the slime will vary in amount and character according to the care taken in drawing and handling the milk. The difference between the bowl slime deposited on the inner wall of the Alpha separator bowl and the "separator dirt," the deposit found at the lower end of the central inlet tube serving as a stand for the Alpha discs, is considered. The latter is dark gray, of a sandy and dry consistency, and contains macroscopic impurities, like parts of insects, animal and human hairs, particles of wood, etc. Viewed under the microscope it is found to contain more solid impurities and less casein and bacteria than the bowl slime, and is especially rich in epithelial cells, which occur only in small quantities in the bowl slime. The separator dirt makes up from 4 to 8 per cent of the total quantity of slime. The difference in the ash contents of the two kinds of slime is marked. The dry substance of the bowl slime was in one instance found to contain 7.1 per cent of ash, against 14.1 per cent in the dry matter of the separator dirt.

The total amount of separator slime obtained in 50 trials varied from 0.02 to 0.04 per cent of the milk separated, the average amount being 0.03 per cent. The average water content was 65 per cent, with variations from day to day of 3 to 4 per cent. The machine used was a Turbine Alpha-Pony separator.

The relation between the separating temperature, the acidity of the milk, and the amount of slime obtained is shown by the following results:

Relation between temperature, acidity of milk, and amount of slime.

	Temperature ° C.									
	40	45	50	55	60	65	70	75	80	85
Lactic acid	<i>Per ct.</i> 0.160	<i>Per ct.</i> 0.165	<i>Per ct.</i> 0.167	<i>Per ct.</i> 0.165	<i>Per ct.</i> 0.168	<i>Per ct.</i> 0.156	<i>Per ct.</i> 0.160	<i>Per ct.</i> 0.165	<i>Per ct.</i> 0.165	<i>Per ct.</i> 0.161
Separator slime.....	.032	.038	.040	.045	.041	.030	.028	.044	.036	.046

The increase in percentage of slime with increasing acidity of the milk is due to the greater separation of the casein under these condi-

tions. Below 70° C. there is a direct increase of slime with the increase in acidity, but above 70° the amount of slime depends on the heat and not on the degree of acidity. Abnormal conditions in the milk (e. g., admixture of colostrum milk) decidedly influence the slime formation. In case of cows attacked with foot-and-mouth disease the slime content of the milk has been found to reach 0.3 per cent of the amount of milk separated, instead of the normal 0.03 per cent.—F. W. WOLL.

Skimming and churning in Swedish creameries, N. ENGSTRÖM (*Tidskr. Landtmän*, 18 (1897), Nos. 38, pp. 685-689; 39, pp. 695-698).—Investigations were conducted during the spring and fall of 1897 to study the losses of butter fat in skimming and churning in the Swedish creameries participating in the periodical butter exhibitions. In all, 508 samples of skim milk were examined, about half of this number being separated at pasteurizing temperature (65 to 85° C.) and the rest separated at 25 to 35° C., with the exception of 35 samples which were from the gravity cold-setting system. Over half of the samples were taken in the spring and the remainder in the fall. In sampling the skim milk, samples of 500 cc. each were taken every half hour on five successive days, and 50 cc. of the united daily samples were used. Ninety per cent of the samples were from De Laval separators, nearly all of which were Alpha separators.

As between the two kinds of Alpha separators, old and new, the average fat content of the skim milk from old-model machines was, pasteurized, 0.09 per cent; unpasteurized, 0.13 per cent; and from the new-model machines, pasteurized, 0.10 per cent; unpasteurized, 0.13 per cent. From 90 to 95 per cent of the samples from pasteurized milk contained under 0.15 per cent fat, and 55 to 60 per cent under 0.1 per cent. Where the skimming was done at lower temperatures the fat content of the skim milk was under 0.15 per cent in 60 to 70 per cent of the cases, and under 0.2 per cent in 86 to 90 per cent of the cases.

The samples of buttermilk analyzed, numbering 459 in all, were composites from the churnings of several successive days. The average results obtained are shown below, with variations. The loss of fat in the buttermilk per 100 kg. of whole milk is also given in the table.

Analyses of samples of buttermilk.

	Fat content of buttermilk.		Loss of fat in buttermilk, per 100 kg. of whole milk.	
	Pasteurized.	Unpasteurized.	Pasteurized.	Unpasteurized.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Kg.</i>	<i>Kg.</i>
Maximum	1.48	0.91	0.26	0.20
Minimum.....	.18	.20	.02	.02
Average.....	.38	.38	.047	.053

The samples from pasteurized milk contained, on the average, the same amount of fat as those from the unpasteurized milk, while the

average loss of fat in the buttermilk per 100 kg. of whole milk, was slightly less in case of the samples from pasteurized milk. This result is contrary to the teachings of the Danish pasteurization experiments (E. S. R., 2, p. 492). The average loss of fat from both pasteurized and unpasteurized milk was 0.049 kg.—F. W. WOLL.

Butter fat in cheese (*Pennsylvania Dept. Agr. Bul. 34, pp. 62-71*).—“In order to settle, in a practical manner, the question of fact as to whether the standard of 32 per cent of butter fat in a full-cream cheese was impracticable, Professors Aschman, Frear, and Cochran were directed to have 100 samples of cheese selected in their respective districts and have them carefully tested for their percentage of butter fat, and it was agreed by all parties interested that the result of this test should be deemed conclusive.”

The results of these analyses are tabulated, Aschman's average being 32.6 per cent of fat; Frear's, 35.3, and Cochran's, 33.6.

“While a number of samples ran below the full-cream standard, there is evidence for the belief that they were in reality ‘skim-milk’ cheese, and would come under one of the lower classifications of the law, but few falling below that of ‘three-fourths cream,’ which requires the presence of 24 per cent of butter fat.”

“[The conclusion is reached] that the standard of 32 per cent of butter fat for a ‘full cream cheese’ is not too high and is readily attainable by any careful and practical manufacturer, and that it is in favor of rather than against the manufacturer.”

To study the variation in the composition of samples taken from different parts of the same cheeses, series of samples were examined by the above analysts, and the results are given. It was found that—

“The slight variation in the amount of butter fat in different portions of the same cheese, the rind being discarded, is not of sufficient amount to influence results, and that even this slight variation may be avoided by taking the samples with a cheese ‘trier,’ which insures a fair section of the cheese.”

To test the variation in fat content of cheese made under practically the same conditions on different days, cheese made by one maker on ten successive days was analyzed. All of the samples contained over 39 per cent of fat, and the variation between the maximum and minimum was 3.42 per cent.

“Under proper management the variation caused by the milk of different days is not of sufficient importance to modify results, especially as it is not the intention of the department to prosecute upon close or small margins.”

The fat content of a number of samples of fancy cheese is given, with the selling price per pound.

The college herd, C. D. SMITH (*Michigan Sta. Rpt. 1896, pp. 102-106*).—The individual record is given for 12 cows for one year, showing the amount and cost of the food eaten, amount of milk and butter produced, profit, etc. The yield of milk ranged from 4,946.6 to 16,981 lbs.; the calculated yield of butter from 173 to 652 lbs.;

the cost of food per pound of butter from 5.5 to 16 cts.; and the net profit from \$6.08 to \$94.05. Except in the case of one cow, the cost of butter was under 9 cts., and the net profit for the year exceeded \$22.

The 3 cows giving the greatest net profit were the 3 cows consuming the most feed. . . . On the other hand, College Dame Le Brocq, the average per cent of fat of whose milk was 6.33 per cent, returned, on account of her large yield of fat, a net profit of \$42.99, although her total cost of feed was but \$36.10, an expense less than that of any other cow in the herd save one. . . .

"These cows vary, evidently, in their capacity to eat and digest food; they vary also in their capacity to return in butter fat an amount corresponding to the feed consumed."

Dairy records. C. D. SMITH (*Michigan Sta. Rpt. 1896*, pp. 223-266, figs. 8).—A reprint of Bulletin 127 of the station (E. S. R., 7, p. 885).

On the occurrence of tubercle bacilli in market butter, L. RABINAWITSCH (*Ztschr. Hyg. u. Infektionskrankh.*, 26 (1897), p. 90; *abs. in Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 20-21, pp. 610-612).

Some of the dangers surrounding the dairy, E. F. BRUSH (*Dietet. and Hyg. Gaz.*, 14 (1898), No. 3, pp. 142-144).

Annual reports of the butter and cheese associations of the Province of Ontario, 1897 (*Toronto: Ontario Dept. Agr.*, 1898, pp. 175).—This contains the proceedings of the annual meeting of the associations, including various papers on the feeding and management of dairy stock, butter making, cheese making, creamery management, etc., with a list of members, financial statements, etc. The papers are largely quite popular, those by the college and station officers being based on work reported in detail elsewhere.

Annual reports of the dairymen's and creameries' associations of the Province of Ontario, 1896 (*Ontario Dept. Agr. Rpt. 1896*, I, pp. 1-280).—The proceedings of the annual meetings of these associations.

Report of cooperative dairy experiments for 1896, H. H. DEAN (*Ontario Dept. Agr. Rpt. 1896*, I, pp. 256-258).—A very brief account is given of cooperative experiments made by private parties on the effect of an increase in the fat content of the milk on the yield and quality of cheese, effect of milling curd at different stages of acidity, effect of putting curd to press at different temperatures, and effect of washing on quality of butter.

Dairy bulletin by the dairy school, Guelph (*Ontario Agr. Col. and Expt. Farm Bul.* 107, pp. 32).—This consists of popular articles by different authors on methods of sewage disposal, milk testing, care of milk for cheese factories and creameries, making a starter, separators and the separation of milk, butter making in the creamery, butter making on the farm, and cheese making.

On the milk trade in large European cities, W. MUNTIE-KAAS (*Tidsskr. Norske Landbr.*, 5 (1898), No. 3, pp. 97-119).

Composition of human milk, A. H. CARTER and H. D. RICHMOND (*Brit. Med. Jour.*, 1898, I, pp. 199-203; *abs. in Jour. Chem. Soc. [London]*, 1898, No. 425, p. 175).

Cheese yeasts and their systematic application in practice, O. JOHAN-OLSEN (*Ber. Andra Nord. Landbr. Kongr., Stockholm, 1897*, I, pp. 465-468; II, App. 17, pp. 9, ill.).

The best medium for lactic acid ferments, O. JENSEN (*Centbl. Bakt. u. Par.*, 2. Abt., 4 (1898), No. 5, pp. 196-199).—The author found a particular kind of peptonized milk furnished the best medium for a number of lactic ferments.

A preliminary bulletin on the pasteurization of milk, C. D. SMITH (*Michigan Sta. Rpt. 1896*, pp. 413-442, figs. 6).—A reprint of Bulletin 134 of the station (E. S. R., 8, p. 630).

On the manufacture of Thyboe cheese, B. BOGGILD (*Ugeskr. Landm.*, 43 (1898), No. 13, pp. 162-164).

Branding cheese (*Pennsylvania Dept. Agr. Bul.* 34, pp. 50-52).—A discussion of the State law requiring the branding of cheese, with some of the difficulties that have been met.

United States vs. Canadian cheese in England, DICKINSON (*U. S. Consular Rpts.*, 1898, No. 112, pp. 109-111).—Statistics are quoted on the export of cheese from Canada and the United States to England. Considerable more cheese was imported from Canada than from the United States. The Canadian cheese was valued at 9.12 cts. per pound and the United States cheese at 9.23 cts.

VETERINARY SCIENCE AND PRACTICE.

On a new infectious disease of cattle, G. BOSSO (*Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 18-19, pp. 537-542, pl. 1).—A disease discovered in the neighborhood of Pavia, Italy, is described which is similar to charbon or hemorrhagic septicemia, but can not be classed as either. It appeared suddenly, developing the following symptoms: Temperature, 39° C.; cud-chewing slow, almost none; weakness in the lumbar region and hinder parts; continued attempt to pass feces; suffering severe. After three or four days the animal's strength disappears and it succumbs, moaning painfully.

In a herd of 21, 6 died. The disease was found on wet places and has been observed on dry or high ground. Infection appears to be through drinking water and food. Autopsy showed the heart, coronal arteries, and veins about the *sulcus ariulo ventricularis* crowded with ecchymoses from the size of a needle point to that of a needle head. The entire surface of the ventricles was covered with them. The blood was reduced to a thin coagulum. The cardiac lymph vessels were very noticeable and were abnormally swollen. The kidneys were very hyperemic, dark red to violet, inclined to black.

Culture studies brought to light a motionless bacterium $1\frac{1}{2} \mu$ by 0.5 to 0.8 μ in size, which resisted many of the usual staining reagents and withstood Gram's decolorizing method. Some obtained from the kidneys, where they are very numerous, measured 2.7 μ long. Injection experiments with guinea pigs, dogs, and white mice resulted fatally in 18, 18 to 24, and 60 hours, respectively.

Histological studies showed that the chief alterations occur in the Malpighian glomerules of the kidneys, where there was found great changes in the vascular walls and a great increase in the number of muscles in the endothelium of the vascular loops and the scaling of the outer epithelium of Bowman's capsules, all of which may be characterized as *Glomerulo nephritis*. The specific organisms can be found in large numbers inside the vessel cells in the lymph spaces.

The disease is very different from the new septicemia with nephritis described by Thomassen as occurring in cattle, some of the differences appearing in the turbid urine in the latter disease and the motile organism. The organism is also distinct from that found in cases of nephritis found by Hess, Pflug, Mazanti, Rivolta, Mircoli, and others.

Some diseases of cattle, N. S. MAYO (*Kansas Sta. Bul.*, 69, pp. 103-134, figs. 2).—This gives a brief popular account of Texas itch, black-leg or symptomatic anthrax, tuberculosis, and Texas fever.

From various parts of the State reports were received of a skin disease, identified as Texas itch, caused by the mite *Psoroptes communis boris*. In the outbreaks observed the mite was introduced on cattle from the ranges of the South and West. The disease spreads rapidly through a bunch of cattle, apparently by contact of the diseased and healthy animals, and indirectly by posts, feed-racks, etc. As remedies, emulsions of creolin and zenoleum (the latter in the proportion of 1 to 3 and applied with sponges, cloths, and scrubbing brushes) gave the best results. The cost is 2 to 3 cts. per head. The lime-sulphur remedy is also recommended.

In opposition to the usual statement that blackleg is more prevalent in low and wet lands, the fact is noted that it seems to cause greater losses in the western part of Kansas, where the altitude is almost 4,000 ft. and the rainfall less than 20 in., than in the eastern part at an altitude of less than 1,000 ft. and an annual rainfall of nearly 40 in. Treatment is thought unsatisfactory and the best remedy is prevention by vaccination.

The results of tuberculin tests are given. From the fact that, according to records collected from various sources, of 11,394 cattle tested in the United States 5,759 reacted, and that the number of errors was 12 or about 1 in 950, the author concludes that the test is very reliable. From the same sources it was found that different breeds seem to be affected in different degrees, as shown in the accompanying table:

Table showing the distribution of tuberculosis by breeds.

Breed.	Number tested.	Number reacting.
Jersey, pure and grades	111	77
Shorthorn, pure and grades	293	91
Holstein, pure and grades	283	127
Ayrshire, pure and grades	18	112
Guernsey, pure and grades	13	7
Devon, pure and grades	20	11
Red Polled, pure and grades	7	3
Aberdeen-Angus, pure and grades	13	8

Experiments were performed in infecting cattle with Texas fever by means of *Boophilus boris*, which completely confirmed conclusions arrived at by Dinwiddie, Francis, Connaway, and the Bureau of Animal Industry. An account is given of several outbreaks of Texas fever. In one case infected cattle were shipped into Kansas from north of the national quarantine line, but were found to have first come from south of it. In another case 170 head of cattle from California communicated the disease to a herd of 350 natives, 30 of which were lost. The comparatively small loss is attributed to the small number of ticks on the California cattle.

Although remedial treatment is not satisfactory, it is thought that some relief may be given by removing sick cattle to shady and comfortable quarters, drenching them with sweet milk and removing the ticks. The quarantine method is the most effective remedy.

A case of a contagious epidemic of pseudotuberculosis in sheep. TURSKÉ (*Zitschr. Milchhyg.*, 9 (1897), No. 7; abs. in *Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 20-21, p. 615).—At a slaughterhouse in Danzig 14 out of a flock of 150 8 to 12 year-old sheep were found infected with a disease identified as pseudotuberculosis. Enlarged glands, which were somewhat evident before death, came to light when the animals were slaughtered. These glands contained abscess-like formations of a greenish yellow color, but neither caseous nor crumbly.

Report of the meeting of the German naturalists and physicians at Brunswick. O. VOGES (*Centbl. Path. u. Par.*, 1. Abt., 22 (1897), No. 22-23, pp. 687-693).—One of the prominent facts brought out in the summary of the papers read on tuberculosis at the meeting is that milk may be tuberculous without the udder itself being affected.

An investigation for the repression of beri-beri. C. ELKMAN (*Arch. Path. Anat. Physiol.* [Virchow], 9 (1897), No. 1, pp. 181-194; abs. in *Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 18-19, pp. 569, 599).—In Java a disease which resembles human beri-beri occurs in rice fed poultry. It is concluded from feeding experiments that some substance occurs in the so-called silver husk of rice that neutralizes the effect of feeding rice to hens.

Studies in immunization against Staphylococcus pyogenes aureus. REICHENBACH (*Beitr. Klin. Chirurgie*, 18, No. 1; abs. in *Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 22-23, pp. 712, 715).

Protective inoculation. (*Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 20-21, pp. 621-630).—A review of fourteen papers on the use of tuberculin and on analogous agents in other diseases.

Parasitological notes. M. STROSSICH (*Pol. Soc. Adriat. Sc. Nat.*, 18 (1897), pp. 1-10, pls. 2; abs. in *Zool. Centbl.*, 5 (1898), No. 1, p. 175).—New hosts are noted for *Ascaris megaloccephala* and other parasites.

On the occurrence of scarlet fever in animals. R. BEHLA (*Centbl. Bakt. u. Par.*, 1. Abt., 21 (1897), No. 20-21, pp. 777-782).

Contribution to the etiology of typhoid affections in the horse. G. P. PIANA and B. GALLI-VALERIO (*Moderno Zooiatro*, 1897; abs. *Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 20-21, p. 615).

On anthrax of the lungs. M. W. PETROFF (*Russ. Archiv. Path. Klin. Med. u. Bakt.*, 3 (1897), No. 6, p. 565; abs. in *Centbl. Bakt. u. Par.*, 1. Abt., 21 (1898), No. 5-6, p. 219).—A case of anthrax in a brush maker is described in detail. The person died within six days. Plenty of evidence was found to show that the germs entered through the respiratory passages. The bacillus was also found in the peri-bronchial and subpleural lymph vessels, in the lymph glands, and in the kidneys and spleen.

Tuberculin investigations at Hamra (Sweden). O. SVENSTRÖM (*Tidskr. Landtmän*, 18 (1897), No. 46, pp. 825-828).—Experiments were made on the application of tuberculin inoculations as a preventive against tuberculosis. It was found that tuberculin is of no benefit for this purpose, and that by making repeated tuberculin injections on healthy animals no reaction may be obtained if the animals are exposed to contagion and after some time again tested with tuberculin. Animals should not therefore be injected too often with tuberculin, viz, not to exceed twice a year. It is furthermore noted that tuberculin will finally fail to give a reaction with animals which have reacted once or several times.—F. W. WOLL.

Bacteriological study on the transmission of Bacillus anthracis from the mother to the fœtus. C. MASSA (*Prif. Med.*, 1896, pp. 120, 121; abs. in *Centbl. Bakt. u. Par.*, 1. Abt., 22 (1897), No. 22-23, p. 704).—Twenty-five animals, representing dogs, guineas, mice, and cats, and 113 fœti were studied. The conclusions drawn are: The transmission of micro-organisms to the fœtus can take place only through placental

lesions. The placenta in charbon changes rapidly after death, undergoing a peculiar decomposition, no bacilli occur, and the dead fetus does not always contain bacilli. These are found only in the blood and in the surrounding amniotic fluid.

New discoveries on Bacillus tuberculosis, its transformation in the common saprophyte, and its resemblance to the Coli bacillus, J. FERRÁN (*Nouvelles découvertes sur le bacille de la tuberculose: La transformation en saprophyte vulgaire et son rapprochement du genera Coli bacilli.* Barcelona, 1897; *abs. in Centbl. Bakt. u. Par., 1. Abt., 22 (1897), No. 16-17, pp. 483, 484*).

Tuberculosis in cattle, E. A. A. GRANGE (*Michigan Sta. Rpt. 1896, pp. 102-112*),—A reprint of Bulletin 133 of the station (E. S. R., 8, p. 625).

An investigation of tuberculosis in the ass, JULME (*Ztschr. Tiermed., 1 (1897), p. 361*; *abs. in Bakt. u. Par., 1. Abt., 22 (1897), No. 20-21, p. 611*).—It was found that the ass is by no means immune to tuberculosis.

A rare case of udder tuberculosis, EHRLHARDT (*Schweiz. Arch. Tierheilk., 1896, pt. 2*; *abs. in Centbl. Bakt. u. Par., 1. Abt., 22 (1897), No. 20-21, pp. 613, 614*).—In a healthy cow that two months previous to slaughtering had been diagnosed as affected with tuberculosis of the udder there was found evidence of old lesions in the udder and of fresh miliary tuberculosis in the lungs.

Investigations of bovine tuberculosis in Finland, 1894-95. C. AHLMAN and H. SAWELA (*Landtbl. Styr. Meddel., 1897, No. 20, pp. 167-189*).

The contest against bovine tuberculosis. B. BANG (*Ber. Andra Nord. Landtbl. Kongr., Stockholm, 1897, 1, pp. 209-229*).

Life history of trichina. J. W. GRAHAM (*Arch. Mikros. Anat., 50 (1897), pp. 219-275, pls. 3*; *abst. Jour. Roy. Micros. Soc. [London], 1898, No. 3, p. 79*).—The fact that young trichina occur in the body cavity free in the tissue and are unequally distributed in the different groups of muscles the author holds is not supported by the idea of active migration, while the fact that embryos occur in the blood, that the embryo has been found in the artery of the diaphragm, that embryos occur in blood clots in the lungs, and the existence of lesions and the bleeding of capillaries, and the rapidity of distribution are arguments in favor of the distribution of the parasite being by means of the blood vessels.

Filaria and Spiroptera, M. STOSSICH (*Bol. Soc. Adriat. Sci. Nat., 18 (1897), pp. 13-162*; *abs. in Zool. Centbl., 5 (1898), No. 4, p. 124*).—A monograph treating of 317 species of parasites belonging to the genera Filaria, Spiroptera, Oxyspirura, Filarioides, Spiroxys, and Gongylonema.

The duration of immunity after illness with foot-and-mouth disease, RENNER (*Berlin Tierärztl. Wehnschr., 27 (1897); abs. in Centbl. Bakt. u. Par., 1. Abt., 22 (1897), No. 20-21, p. 621*).—A half year after the disease affected a herd of cattle it appeared again. The animals that had been affected in the first attack escaped the second.

The struggle with foot-and-mouth disease. HOENE (*Berlin Tierärztl. Wehnschr., 27 (1897); abs. in Centbl. Bakt. u. Par., 1. Abt., 22 (1897), No. 20-21, p. 621*).

Observations on the etiology of foot-and-mouth disease, V. BABES and G. PROCA (*Centbl. Bakt. u. Par., 1. Abt., 21 (1897), No. 22-23, pp. 835-849, figs. 5*).—The author found several bacterial forms and believes that he has isolated one, a fungoid-bacterioid, that is the cause of the disease. This form is of uncertain position, but it calls to mind Babes's *Ascobacterium luteum*. Injection of cultures produced the fever.

The causes and importance of udder diseases, J. WENNERHOLM (*Ber. Andra Nord. Landtbl. Kongr., Stockholm, 1897, 1, pp. 160-173*).

A case of three-fold infection. L. GUSSEW (*Centbl. Bakt. u. Par., 1. Abt., 21 (1897), No. 22-23, pp. 849-857, fig. 1*).—Infection with Bacillus of charbon, a pus-forming Streptococcus, and Fraenkel's Diplococcus.

The origin of tetanus antitoxin in the animal body and its relation to tetanus poison, A. KNORR (*Fortschr. Med., 1897, No. 17*; *abs. in Centbl. Bakt. u. Par., 1. Abt., 22 (1897), No. 18-19, pp. 567-568*).

Topographical anatomy of the horse. W. ELLENBERGER and H. BAUM (*Topographische Anatomie des Pferdes*. Berlin: Paul Parey, 1897, 3 vols., pp. 951: rev. in *Nature*, 56 (1897), No. 1469, p. 586).

TECHNOLOGY.

Paints and painting materials and miscellaneous analyses. H. HARRINGTON and P. S. TILSON (*Texas Sta. Bul.* 11, pp. 961-973).—Tests of the drying properties of crude and refined cotton-seed oil and analyses of thirteen samples of commercial paints are reported. The conclusion is drawn that cotton-seed oil may be used for rough outside painting in summer weather, especially if mixed with a dryer, but in no case will it give the luster or hardness which may be obtained with linseed oil. "Its durability may, however, be even better." It is recommended to buy the oil and pigments separately and mix them to suit, rather than to buy the ready mixed paints.

Analyses of 36 samples of mineral waters, 2 of damaged cotton-seed meal, 6 of coal, 4 of copper ore, 2 of iron ore, 2 of clay, 1 of fertilizer, 1 of calcareous shells, 2 of asphalt, 2 of ashes, and 2 of satol (whole plant and inner portion), and the results of an examination of 2 distillation by-products from lignite tar are also reported.

Notes on cold storage. F. W. RANE (*Proc. Soc. Prom. Agr. Sci.*, 1897, pp. 53-59).—This is a general discussion of the use of cold storage for the preservation of agricultural products of various kinds, including an account of a cold-storage cellar constructed at the New Hampshire Station in which apples and potatoes were successfully stored. The principle upon which this storage cellar was constructed is thus explained:

"It might be termed climate cold storage, and consists of studying and husbanding the lowest temperatures of one's climate to do one's bidding. There are few days at a stretch from September until late in spring in New England, for instance, but that the temperature falls at some time sufficiently to utilize it for cold storage. Being prepared to retain this temperature in cellars or buildings constructed for the purpose until a similar or lower temperature is again realized is the key to its success. From experience it is believed this simple method can with comparatively little care and expense be made more useful at present (in this our transitory stage) than all others. It is not offered to take the place of other systems already mentioned, but to meet an apparent need in our rural districts."

Wool scouring. E. F. LADD (*North Dakota Sta. Bul.* 32, p. 271).—The losses in weight from scouring three samples of wool were 60.01 per cent, 62.64 per cent, and 61.77 per cent. It is stated that these were "fair samples from the sheep as found on the prairies in the sheep belt of the western part of the State. . . . Data that have come under the observation of the writer have shown a loss of from 55 to 70 per cent from scouring samples of North Dakota wool."

On the natural occurrence of large amounts of potassium chlorid and sodium chlorid in the juice of grapes and in the wines of the saline regions of Oran. E. BONJEAN (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 18, pp. 1275-1277).—The French law requires that wine shall not contain more than 0.607 gm. of chlorin per liter. The author found more than this in grapes of the province of Oran and in the wine made from these grapes.

A study of some bad wines, E. KAYSER and G. BARBA (*Ann. Sci. Agron.*, 1898, 1, No. 1, pp. 25-39).

Castor oil manufacture (*Producers' Gaz. and Settlers' Record [Western Australia]*, 5 (1898), No. 2, p. 127).—A short note on the method of extracting the oil.

AGRICULTURAL ENGINEERING.

Progress in timber physics, B. E. FERNOW (*U. S. Dept. Agr., Division of Forestry Circ.* 18, pp. 20, *diagms.* 11, *tables* 10).—The influence of size on test results and distribution of moisture as factors in timber physics are reported upon at some length. The circular also contains some notes by S. T. Neely on the "Endwise-compression strength to breaking load of beams." The most important conclusions given in the circular are as follows:

"A difference in strength values derived from a few specimens of the same kind of wood, up to 10 per cent for coniferous wood and to 15 per cent for hard woods, can not be considered a difference of practical importance: such differences can not be relied upon as furnishing a criterion of the quality of the material.

"The size of the test piece does not in itself influence strength values (except in compression endwise when the size is less than a cube).

"Small test pieces judiciously selected furnish a better statement of average values of a species than tests on large beams and columns in small numbers.

"A large series of tests on small pieces will give practically the same result as such a series on large beams and columns; hence, there is no need of finding a coefficient with which to relate the results of the former to construction members.

"The influence of moisture on strength appears even greater than the former tests and statements from this Division have indicated."

The most important discovery of all is that worked out by S. T. Neely, as follows:

"The strength of beams at elastic limit is equal to the strength of the material in compression, and the strength of beams at rupture can, it appears, be directly calculated from the compression strength; the relation of compression strength to the breaking load of a beam is capable of mathematical expression."

Dynamometer tests on farm wagons, C. D. SMITH (*Michigan Sta. Rpt.* 1896, p. 110).—"On good roads the draft of wide and narrow tired wagons was about equal. On plowed land a narrow tired wagon pulled 45 per cent harder than one with wide tires; on a road with sand 2 in. deep, 25 per cent harder; and on sod, 16 per cent harder. A wagon not greased pulled 18 per cent harder than one greased."

Shrinkage of cord wood, C. D. SMITH (*Michigan Sta. Rpt.* 1896, pp. 110, 111).—Five cords of freshly cut, 18-in. green beech wood weighed 14,336 lbs. on February 7. The wood was piled out of doors, and on October 9 it weighed 7,148 lbs. "Twenty cords of 18-in. slab wood split into stove wood gained 10 per cent in bulk in the operation."

Drainage by means of fascines, R. SCHMOLDT (*Deut. Landw. Presse.* 5 (1898), No. 24, p. 262).

Windmills, M. RINGELMANN (*Jour. Agr. Prat.*, 62 (1898), 1, No. 21, pp. 761, 762).

Irrigation on our farm, R. HITTINGER (*Agr. of Massachusetts*, 1897, pp. 141, 142, *fig. 1*).—An account is given of the irrigation of a farm and greenhouses from two artesian wells, the water being raised by a windmill and a steam pump and applied through pipes and revolving sprinklers.

Irrigation in Utah, C. H. BROUGH (*Baltimore: The Johns Hopkins Press, 1898, pp. XI + 212, pls. 1*).—The book is divided into two parts. (1) economic history of irrigation in Utah, including the formation of the cooperative system (1847-48), economic development under the cooperative system (1848-1862), early legislation (1862-1867), transportation and commerce as aids to irrigation (1867-1877), recent legislation (1877-1897), capitalistic irrigation (1890-189-), development of agriculture through irrigation, development of horticulture through irrigation, and relation of irrigation to other factors of Utah's industrial system; (2) problems of irrigation in Utah, including advantages of reclaiming the remaining irrigable land, methods of reclaiming the whole body of irrigable land, administration of irrigable land already ceded to the State, State control of water, necessity for more accurate means of measuring water, and marketing of irrigation products. Miscellaneous information and data are given in an appendix.

Sewage disposal, B. F. LA RIE (*Sci. Amer. Sup., 45 (1898), No. 1171, p. 18743, fig. 1*).—Different methods of sewage disposal are discussed, broad irrigation being considered "the most satisfactory and effectual means of sewage purification yet tried where suitable land can be procured."

Notes on the employment of convicts in connection with road building, R. STONE (*U. S. Dept. Agr., Office of Road Inquiry Bul. 16, rev., pp. 21, figs. 4*).—A reprint of Bulletin 16 of the Office of Road Inquiry of this Department (*E. S. R., 7, p. 258*), with some additional matter on the subject supplied by various officers in South Carolina, California, and New York.

Swine pasture fences, S. M. EMERY (*Montana Sta. Bul. 14, p. 34*).—Barbed wire fences for pig pastures at the station have proved unsatisfactory, and board fences are objectionable because of their expense and tendency to collect snow drifts. The author recommends the use of woven wire for the purpose.

Building silos, C. D. SMITH (*Michigan Sta. Spec. Bul. 6, pp. 17, figs. 10*).—General considerations in the construction of silos are discussed and methods of construction of stave silos, round silos with horizontal lining, and rectangular and square silos are explained, with plans and specifications.

STATISTICS—MISCELLANEOUS.

Tenth Annual Report of Kansas Station, 1897 (*Kansas Sta. Rpt. 1897, pp. XX*).—This contains the financial report for the fiscal year ending June 30, 1897, and the report of the council giving an outline of Bulletins 65 to 71 published by the station during the year and an account of the work in progress of the different departments. The station staff was changed September 1, 1897, and shows an almost complete reorganization.

Ninth Annual Report of Michigan Station, 1896 (*Michigan Sta. Rpt. 1896, pp. 93-469*).—A financial statement for the fiscal year ending June 30, 1896; short reports by the director and heads of departments, including detailed reports of the apiarist, meteorologist, horticulturist, agriculturist, and botanist (noted elsewhere) on the work of the year, and reprints of Bulletins 125 to 134 of the station.

Tenth Annual Report of Tennessee Station, 1897 (*Tennessee Sta. Rpt. 1897, pp. 152-165*).—Contains the report of the treasurer for the fiscal year ending June 30, 1897, brief reports by the heads of the various departments on the work of the year, a general review of the work of the station by the secretary, and a list of the publications of the station since its organization in 1888.

Historical Sketch of the United States Department of Agriculture; its objects and present organization, C. H. GREATHOUSE and G. W. HILL (*U. S. Dept. Agr., Division of Publications Bul. 3, pp. 74, pls. 3, figs. 10*).—This sketch is compiled from the annual reports of the several Commissioners and Secretaries of Agriculture and deals with the history, work, and growth of the Department under the different administrations since its organization. It is supplemented with a statement of the origin and duties of the several bureaus, divisions, and offices of the Depart-

ment . . . and by citations from the several laws under which the Department has attained its present state of development."

Of what service are statistics to the farmer? J. HYDE (*U. S. Dept. Agr., Division of Statistics Bul. 14, misc. ser., pp. 258-270*).—A popular discussion of the value of statistical information to agricultural interests. (Reprinted from the Yearbook of the Department of Agriculture for 1897, pp. 258-270.)

Experiment station work—IV (*U. S. Dept. Agr., Farmers' Bul. 73, pp. 31, figs. 3*).—This is the fourth number of this series of popular bulletins based upon experiment station work in this and foreign countries. The following subjects are discussed: Pure water, loss of soil fertility, availability of fertilizers, seed selection, Jerusalem artichoke, Kañr corn, thinning fruit, use of low-grade apples, cooking vegetables, condimental feeding stuffs, steer and heifer beef, and swells in canned vegetables.

Trade of Porto Rico, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 13, pp. 84*).—A statistical review of the foreign trade of Porto Rico, showing the nature, amount, and value of the principal imports and exports, the countries with which most of the trade is carried on, etc., for each of the ten years ending with 1896. The total export trade of Porto Rico in 1896 amounted to \$18,341,130 and the total import trade to \$18,282,690. The principal exports of Porto Rico are sugar and coffee. These constitute fully 85 per cent of all agricultural merchandise sent from the island to foreign markets. More than 99 per cent of the coffee is sent to Spain, Cuba, and France, and less than 1 per cent to the United States. Out of 122,946,335 pounds of sugar exported from Porto Rico in 1896, 71,875,614 pounds were sent to the United States. Spain received the next largest amount, 43,600,064 pounds. The principal imports of Porto Rico are rice, wheat flour, and hog products. The two latter are obtained principally from the United States and the former from the British East Indies and through German and Spanish sources.

Crop circulars for May and June, 1898 (*U. S. Dept. Agr., Division of Statistics Crop Circ. May, pp. 3; June, pp. 4*).—The circular for May is the first of a series of crop circulars designed to take the place of the now series crop reports heretofore issued. It gives the acreage and condition of wheat, rye, cotton, meadows, and spring pasture, and notes the progress of spring plowing in the different States and Territories up to the first day of May. The June circular extends this information to June 1 and contains in addition a compiled summary of climatic conditions during the spring months of 1898.

Report on crops, live stock, etc., in Manitoba, 1898 (*Ontario Dept. Agr. and Immigr. Bul. 55, pp. 19*).—Information relative to acreage and condition of the crops, live stock, etc., the rainfall, and other climatic conditions, compiled from the reports of about 350 correspondents. A list of the creameries and cheese factories in Manitoba, with the name and address of secretary of each, is included in the report.

Crops and live stock in Ontario (*Ontario Bureau Ind. Bul. 65, pp. 8*).—A report on the rainfall and temperature of the winter months and on the status of fall wheat, clover, vegetation, live stock, farm supplies, etc., with remarks of correspondents, and farm statistics for Manitoba for 1897.

The development of agriculture in Ontario, C. C. JAMES (*Ontario Bureau Ind. Rpt. 1896, App., pp. 24-48*).—A semi-statistical paper dealing with the history and progress of agriculture in Ontario.

Brief review of the activity of the Ministry of Agriculture and Government Estates during the second year of its existence, March 30, 1895-March 30, 1896 (*St. Petersburg, 1896, pp. 234, 1; abs. in Selsk. Khoz. i Lyesor., 185 (1897), May, pp. 481, 482*).—Among the features of the work were the following: Seven new lower agricultural schools were opened. In the agricultural school at Charkov a new department has been established for the study of the methods of teaching agricultural subjects and applied natural sciences. In 42 places courses in agriculture have been introduced for the teachers in public schools. The number of instructors in dairying has been increased and the sphere of their activity widened. Of the work in

separate branches of agriculture may be mentioned the efforts to introduce improved races of cattle and hogs by buying good stock and selling it to the farmers on easy terms.—P. FIREMAN.

Description of individual Russian farms (*Selsk. Khoz. i Lyesor.*, 186 (1897), July, pp. 1-71; Aug., pp. 315-376; 187 (1897), Oct., pp. 1-95; Nov., pp. 241-280; Dec., pp. 493-577).—The Ministry of Agriculture commissioned a number of experts to describe the methods of farming in different localities of Russia by describing individual farms, especially those that present some particular points of interest. The object was two-fold: (1) to familiarize the farmers with the successful improvements and innovations, and (2) to spread information as to the places where proper seeds, fruit trees, pure-blooded animals, etc., could be directly obtained without the intervention of middlemen. Through the latter means it was hoped that direct cooperation between agriculturists would be encouraged and confidence in useful innovations increased.—P. FIREMAN.

Review of the activity of the Ministry of Agriculture and Government Estates for the third year of its existence, March 30, 1896-March 30, 1897 (*St. Petersburg. 1897.*, pp. VI, 389; *abs. in Selsk. Khoz. i Lyesor.*, 187 (1897), Oct. p. 231). Among the most important work accomplished during this period was the solution in a legislative way of the questions of granting loans for agricultural improvements and of providing the peasants with land in four Siberian governments—Tobolsk, Tomsk, Yeniseisk, and Irkoutsk. Of the measures which are proposed especial stress is laid on the spreading agricultural information, in part among women, by establishing corresponding secondary and lower schools.—P. FIREMAN.

Agricultural holdings in Germany (*Jour. Bd. Agr. [London]*, 5, No. 1, pp. 29-35).—Size and modes of tenure of agricultural land in Germany and a comparison with the holdings in Great Britain.

Finnish agriculture, N. GROTFELT (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, I.*, pp. 240-256).

Catalogue of reports and bulletins of New Jersey Stations and index of reports, 1880-1897 (*New Jersey Stat. Spec. Bul. R.*, pp. 44).

Accessions to the Department library, January-March, 1898 (*U. S. Dept. Agr., Library Bul. Apr.*, 1898, pp. 37).

The promotion of agricultural science, I. P. ROBERTS (*Proc. Soc. Prom. Agr. Sci.*, 1897, pp. 82-85).—Suggestions as to methods of making information in agricultural science available to the rural population of the country.

Agricultural association in the Scandinavian countries, P. FAHLBECK, G. TANDBERG, and J. C. LA COUR (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, I.*, pp. 490-518; *II, App. 15*, pp. 15).

Report of the Chemical and Seed Control Station at Aabo, Finland, 1895 (*Landtbr. Styr. Meddel.*, 1897, No. 19, pp. 139, 140).

Agricultural counselors in the Scandinavian countries, J. NATHORST (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, I.*, pp. 51-52).

Agricultural education in Spain (*Jour. Bd. Agr. [London]*, 5, No. 1, p. 79).—A short note giving a general description of agricultural education in Spain. The annual expenditure on agricultural education, including the payment of agricultural engineers, experts, foremen, etc., is a little over \$280,000.

Report on agricultural education in Denmark, M. HEY (*Bul. [Min. Agr. France]*, 16 (1897), No. 1, pp. 147-168).—A description of the system of agricultural education in Denmark.

Technical instruction for farm women, H. TVETER (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, I.*, pp. 282-286; *II, App. 7*, pp. 14).

Agricultural institutions in Denmark, N. HEYMAN (*Ber. Andra Nord. Landtbr. Kongr., Stockholm, 1897, I.*, pp. 207-209).

Bird day in the schools, T. S. PALMER (*U. S. Dept. Agr., Biological Survey Circ.*, 17, pp. 4).—A popular circular designed to awaken an interest in birds and establish a day on which special attention will be given to birds in schools, etc.

NOTES.

ARIZONA STATION.—C. S. Parsons has been appointed director and irrigation engineer of the station, to succeed J. W. Toumey, who has been acting director since November 1, 1897. Professor Toumey will confine himself to botany and entomology. S. M. Woodward has been appointed meteorologist of the station, to succeed N. H. Barnes, resigned.

FLORIDA STATION.—At the annual meeting of the board of control, held June 11, it was voted to build an experimental tobacco-curing barn and laboratory. The plans adopted include two curing or drying rooms, provided with artificial heat; a sweat room, and a bacteriological laboratory. The entire process of curing the crop, including all the stages from the field to the rolling of the cigar, are to be scientifically studied, with a view to discovering the causes of the changes taking place and to studying the possibility of controlling these changes and producing them at will. This laboratory is believed to be the only one in existence devoted to this work.

GEORGIA COLLEGE AND STATION.—H. N. Starnes has resigned his position as horticulturist of the station, to take effect January 1, 1899, and has been elected professor of agriculture and horticulture in the college. A. L. Quaintance, assistant biologist of the Florida Experiment Station, has been elected to fill the vacancy caused by Professor Starnes's resignation.

INDIANA STATION.—A. H. Bryan has been elected assistant chemist of the station.

IOWA COLLEGE AND STATION.—The following changes have been made in the board of trustees: Governor L. M. Shaw, and R. C. Barret, superintendent of public instruction, have become members *ex officio*, and S. H. Watkins, of Libertyville; C. S. Barclay, of West Liberty, and W. B. Penick, of Tingley, have been appointed in place of C. M. Dunbar, Hamilton Smith, and A. B. Shaw. The following additions have been made to the station staff: Joseph J. Edgerton, assistant in agricultural physics; F. W. Bouska, assistant in dairying; and Miss C. M. King, entomological and botanical artist.

A sheep barn, 32 by 40 ft., with wings 16 by 100 ft., is being built. The leading lines of railway are arranging to cooperate in running excursions to the station and college at a very low rate.

The dairy department is now furnishing the U. S. Department of Agriculture with 1,000 lbs. of butter a week for export to foreign markets. An extensive farm implement storage room is now being constructed, which will facilitate the work of instruction in agricultural physics.

NEBRASKA UNIVERSITY AND STATION.—The board of regents at their June meeting established a department of animal husbandry, to be in charge of C. H. Eluendorf. Vergil C. Barber, A. B., of the university, was appointed assistant to Dr. Peters in the department of animal pathology. R. A. Emerson, B. Sc. of the Office of Experiment Stations, was appointed assistant professor of horticulture, to succeed F. W. Card, resigned, the appointment to take effect April 1, 1899.

NEW YORK CORNELL STATION.—Wilhelm Miller has been appointed assistant in horticultural work and has charge of experiments with chrysanthemums.

OREGON STATION.—B. L. Pague, of Portland, has been elected a member of the board of regents, *vice* Samuel Hughes, deceased.

TEXAS COLLEGE AND STATION.—At the annual meeting of the board of directors L. L. McGinnis, of Bryan, was elected treasurer, *vice* L. L. Foster.

The first Farmers' Congress was held at the college July 13-15. In connection with this congress meetings were held of the Texas State Horticultural Society, the State Swine Breeders' Association, and the State Dairymen's Association. The congress was well attended and successful in every way.

WYOMING UNIVERSITY AND STATION.—E. E. Smiley has been elected president of the university and director of the station, *vice* F. P. Graves, who has resigned, to accept the presidency of the University of Washington.

STATION FOR PLANT PROTECTION AT HAMBURG, GERMANY.—A station for plant protection has been established at Freihafen, near Hamburg. Dr. C. Brick, of the Botanical Museum of Hamburg, has been appointed director of the station and Dr. L. Reh, zoologist. The establishment of the station grew out of the discussion of the danger of the introduction of the San José scale by means of American fruits. It will also be the duty of the station to control the importation of live plants from foreign countries, investigate means of repression in the case of outbreaks of plant diseases, and exercise control over the great nurseries, vineyards, and fruit orchards in the region.

EXPERIMENT STATION RECORD,

EDITED BY

A. C. TRUE, PH. D., *Director.*

AND

E. W. ALLEN, PH. D., Assistant Director—Chemistry, Dairy Farming, and Dairying.
W. H. BEAL—Meteorology, Fertilizers (including methods of analysis), Soils, and
Agricultural Engineering.

Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. X, No. 3.

Editorial notes:	Page.
Irrigation investigations	201
An Egyptian school of agriculture	202
Physical and meteorological researches, principally on solar rays, made at the station of agricultural climatology at the observatory of Juvisy, C. Flam- marion	203
Recent work in agricultural science	214
Notes	299

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

Legumin and other proteids of the pea, lentil, horse bean, and vetch, T. B. Osborne and G. F. Campbell	214
Proteids of the soy bean, T. B. Osborne and G. F. Campbell	218
On the solubility of tricalcium phosphate and apatite in water, J. Joffrè	218
A method for distinguishing bone phosphate from mineral phosphate, F. Mar- tinotti	219

BOTANY.

Investigations on the native vegetation of alkali lands, J. B. Davy	220
Investigations on various economic plants, J. B. Davy	222
Acidity of the root sap of citrus trees, E. W. Hilgard	223

METEOROLOGY.

Meteorological observations, A. O. Leuschner and C. H. Shinn	224
Meteorological record for 1896	225

WATER—SOILS.

	Page.
Analyses of waters.....	228
Alkali and alkali soils, R. H. Loughbridge.....	225
A chemical study of some typical soils of the Florida peninsula, A. A. Persons.....	226
Soils of San Joaquin Valley Substation, California, C. H. Shinn.....	229
Physical effects of lime on soils, J. B. Reynolds.....	228
Experiments in capillarity with long tubes, J. B. Reynolds.....	228
Soil temperatures.....	229
Rocks, clays, coals, plants, and miscellaneous substances.....	229
Examination of soils.....	229

FERTILIZERS.

Improvement and fertilization of land, E. W. Hilgard.....	235
Commercial fertilizers.....	229
Composition of the ashes of different woods, R. Harcourt.....	232
Experiments on the availability of fertilizer nitrogen, S. W. Johnson, E. H. Jenkins, and W. E. Britton.....	232
Alkali, C. H. Shinn.....	235

FIELD CROPS.

Report of the agricultural department, W. C. Latta.....	236
Chicory growing as an addition to the resources of the American farmer, M. G. Kains.....	236
Analyses of cañaigne or tanners' dock, G. E. Colby.....	244
Experiments with field roots, silage, and forage crops, C. A. Zavitz.....	237
Report of grasses and fodder plants, A. B. Leckenby.....	244
Report on grasses and forage plants, E. J. Wickson.....	245
Notes on hay growing, C. H. Shinn.....	245

EXPERIMENT STATION RECORD.

VOL. X.

No. 3.

In the appropriation act for this Department for the current fiscal year ten thousand dollars was provided by Congress "for the purpose of collecting from agricultural colleges, agricultural experiment stations, and other sources, including the employment of practical agents, valuable information and data on the subject of irrigation, and publishing the same in bulletin form." The general supervision of this work has been assigned to the Director of this Office. It was decided that the best way in which the Office could get the advice which it needed for the formulation of plans of work along the most useful lines was to call a conference in the irrigated region of experiment station officers and irrigation engineers who had been most largely engaged in recent years in making experimental inquiries in irrigation, or in dealing with the administrative and practical problems involved in the use of water for irrigation in the West. This conference was held at Denver, July 12 and 13, 1898, and was attended by experiment station officers from California, Nebraska, Colorado, Utah, Montana, and Wyoming, and the State engineers of Wyoming and Colorado.

After careful consideration it has been determined to confine the work on irrigation for the present to two general lines: (1) The collation and publication of information regarding the laws and institutions of the irrigated region in their relation to agriculture, and (2) the publication of available information regarding the use of irrigation waters in agriculture as shown by actual experience of farmers and by experimental investigations, and the encouragement of further investigations in this line by the experiment stations.

The proposed investigation of the actual amounts of water used by successful farmers in different parts of the irrigated region on different soils and in the growing of different crops is believed to be a fundamental inquiry. If sufficient funds are provided for its accomplishment on an adequate scale, it will furnish the basis not only for just court decisions and the equitable apportionment of water by administrative officers, but also for the more systematic and scientific inquiries with a view to the determination of the minimum amounts of water required for successful agriculture under different conditions, and the maximum area which can be properly irrigated in any given locality.

This investigation should be planned and prosecuted in a manner which its importance demands. The work should be begun at once and pushed rapidly to completion. Every year's delay in this undertaking makes the task of a proper settlement of the great water problems of the semiarid region more difficult and perplexing.

The experiment stations are already conducting considerable useful work on problems relating to irrigation farming. They need, however, in several States to concentrate their energies and funds more fully on these problems. And in the larger enterprises they might well have the aid of this Department if means were provided by Congress for this purpose.

We have received the regulations and syllabus of the School of Agriculture, Ghizeh, Egypt, as approved by the minister of public instruction August 14, 1898. From this document we learn that the course of study extends over four years and includes practical and theoretical agriculture, agricultural chemistry, natural science, theoretical and practical chemistry, farm bookkeeping, land surveying, hydraulics, veterinary science, physics, arithmetic, algebra and geometry, trigonometry, Arabic language, and English language. Eight hours a week throughout the course are given to practical exercises in agriculture. Each pupil is allotted a plat of land which he must cultivate with his own hands, "the employment of hired labor or other assistance being absolutely prohibited." This plat consists of one-quarter of a feddan (1.038 acres) the first year, half a feddan the second year, and three-fourths the third and fourth years. "Every pupil shall be allowed to dispose of the produce of his plat, subject to the approval of the principal."

To be admitted to the school the pupils must be at least 14 years of age and must pass an entrance examination. The annual fees for tuition and other expenses are £15 for day pupils and £25 for boarders. The fee for day pupils covers the cost of a mid-day meal provided at the school. Pupils may be admitted to the school free of charge, at the discretion of the minister, provided they are in needy circumstances.

The instruction in theoretical agriculture includes such subjects as soils, climate, tillage, manuring, the feeding and breeding of farm animals, dairying, culture of different crops, construction and sanitation of farm buildings, and agricultural implements. Special attention is given to irrigation and the culture of crops especially suited to local conditions, among which are rice, cotton, sugar cane, berseem (Egyptian clover, *Trifolium alexandrinum*), beans, wheat, barley, maize, peanuts, flax, potatoes, sesame, indigo, fenugreek, chick-peas, and alfalfa. Sugar making and the extraction of cotton-seed oil and indigo are also taught. A special topic is the treatment of the salt lands in upper and lower Egypt, including washing, reclaiming, and cropping.

PHYSICAL AND METEOROLOGICAL RESEARCHES, PRINCIPALLY ON SOLAR RAYS, MADE AT THE STATION OF AGRICULTURAL CLIMATOLOGY AT THE OBSERVATORY OF JUVISY.¹

CAMILLE FLAMMARION,
Director of the Station.

THE SUN AND THE TEMPERATURE.

There appears to be a very curious relation between the annual temperature and the variation of the sun spots, which seems to indicate a certain correlation between the two phenomena. It is known that in the manifestation of its activity the sun exhibits a certain periodicity: there are dark spots, facule or illuminated spots, and eruptions. This period is about 11 years. The last maximum occurred in 1893 and corresponded with the maximum temperature, not only in France, but in many other parts of Europe. The last minimum occurred from 1887 to 1890. This corresponded with a series of cold years. Below is given the extent of the spotted solar surface in millionths of the visible solar hemisphere, calculated from data collected at Greenwich, Dehra-Doon (India), and the island of Mauritius, and the average temperatures of each year in Paris.

Relation between sun spots and temperature.

Year.	Aver. annual temperature.	Extent of sun spots.	Year.	Aver. annual temperature.	Extent of sun spots.
	<i>Deg. C.</i>			<i>Deg. C.</i>	
1878	10.0	22	1888	8.9	89
1879	8.2	45	1889	9.5	78
1880	10.6	408	1890	9.3	99
1881	9.8	740	1891	9.5	569
1882	10.2	1,002	1892	10.2	1,214
1883	9.9	1,155	1893	10.8	1,464
1884	10.5	1,079	1894	10.4	1,282
1885	9.8	811	1895	9.9	974
1886	10.3	381	1896	9.8	530
1887	8.8	178			

The data are shown graphically in fig. 5 (see p. 204).

By adding the years by complets the effects of local disturbances and

¹ Continued from page 114.

the great irregularities of temperature will be equalized. Taking the

FIG. 5.—Relation between annual temperature and sun spots.

average of each couplet, the following figures will be obtained in regard to temperature and sun spots:

Relation between sun spots and temperature.

Year.	Temperature.	Sun spots.	Year.	Temperature.	Sun spots.
1878-79	Deg. C.	34	1887-88	Deg. C.	133
1879-80	9.1	227	1888-89	8.9	83
1880-81	9.4	574	1889-90	9.2	88
1881-82	10.2	871	1890-91	9.4	334
1882-83	10.0	1,078	1891-92	9.9	892
1883-84	10.9	1,117	1892-93	10.5	1,339
1884-85	10.2	945	1893-94	10.6	1,407
1885-86	10.1	596	1894-95	10.2	1,128
1886-87	9.6	279	1895-96	9.9	752

If these figures are represented graphically they will give the diagram in fig. 6. This data is submitted without comment to the judgment of astronomers and meteorologists. Observations at Brussels, London, Edinburgh, Berlin, Prague, Lyons, Bordeaux, Toulouse, Arles, Marseilles, Perpignan, and Montpellier agree with the results at Paris, while other European stations show contradictory results. The sun

spots, the faculae, and the eruptions are certainly an indication of a greater activity of the sun. It is not surprising, then, if the epochs of the maximum correspond with years of higher temperature. An increase of heat may, however, produce cold; for instance, the melting

FIG. 6.—Relation between temperature and sun spots, using 2-year averages.

of ice in the polar regions, resulting in the detaching of icebergs by causing cold currents in the sea, will produce a low temperature in some region.

STUDY OF THE SOLAR RADIATION.

It is possible, by means of proper apparatus, to measure the caloric and luminous radiations of the sun. This can be effected either by allowing the radiations to act together or by separating and distinguishing their relative actions. The apparatus at the station consisted of a Violle actinometric register, a brilliant gilded and black combined thermometer, two vaporizing actinometers, a sunshine register, an horal photometer, and a Cooke radiometer. A record made in 1896 showed the following amounts of heat, by months:

Total amount of heat at Jurisy during 1896.

Month.	Calories.	Month.	Calories.
January	2,582	August	11,918
February	6,467	September	9,368
March	9,862	October	5,477
April	11,776	November	3,576
May	18,606	December	2,034
June	14,778		
July	15,393	Total	111,837

The year 1895 gave 144,411 calories. By means of silver-print paper, which is more sensitive than the paper prepared with prussiate of iron, the number of hours of sunshine are registered. The following table shows the total number of hours of sunshine and the theoretical number—i. e., the number of hours between sunrise and sunset:

Hours of sunshine at Juvisy in 1896.

Month.	Actual.	Theoretical.	Month.	Actual.	Theoretical.
January.....	15.07	268.04	August.....	122.50	436.48
February.....	77.40	280.40	September.....	120.30	371.28
March.....	92.23	364.30	October.....	90.35	328.38
April.....	126.30	407.52	November.....	55.40	269.16
May.....	269.00	468.29	December.....	25.00	251.35
June.....	191.15	476.25			
July.....	212.05	478.57	Total.....	1,398.35	4,402.72

The proportion of hours of actual sunshine was but 32 per cent. The greatest amount of sunshine occurred during May and the least during January and December. In 1895 the register showed 1,817.15 hours of sunshine.

TEMPERATURE OF THE AIR.

The temperature of the air in the shade was observed and registered daily by means of a standard thermometer and with maximum and minimum thermometers.

Average temperature of the air at Juvisy during 1896.

Month.	Average for 24 hours.	Average of maximum and minimum.	Remarks.
	<i>Deg. C.</i>	<i>Deg. C.</i>	
January.....	2.68	2.76	Mild.
February.....	2.65	2.82	Cold.
March.....	8.36	8.60	Warm.
April.....	9.39	9.97	Normal.
May.....	13.01	12.62	Do.
June.....	17.48	17.50	Warm.
July.....	19.20	18.80	Very warm.
August.....	15.82	15.91	Cold.
September.....	14.42	15.00	Fresh and rainy.
October.....	8.34	8.82	Do.
November.....	2.82	3.13	Cold.
December.....	3.50	3.74	Mild.
Average.....	9.80	9.98	

If the average of 365 days of the year be taken, the annual temperature will be 9.84° instead of 9.80°. In 1896 January was very warm, 0.7° above the normal. February was very dry and relatively cold, 1° below the normal. In conclusion, the winter was warm and the rainfall much less than normal. Spring was warm and dry. During May the rainfall at Juvisy was only 3.2 mm., the smallest rainfall during May for a century, except May 1880, when a lighter rainfall, 1 mm., was recorded, with the same temperature. The drought was extreme almost all over France and the harvest was threatened. During June

heavy rains revived the meadows and permitted the culture of a middling harvest. Hay was scarce. The temperature was very favorable during the period of growth but the rainfall was deficient. The long drought was followed by a period of rain, storms, and cyclones, which lasted until the end of autumn. These abundant rains retarded the autumn sowing and seriously affected the vintage which had promised so magnificently. Wine was plenty, but of poor quality. The autumn temperature was very cold and considerably lower than normal. Winter and spring until May were warm and dry, the summer almost normal, while autumn was cold and rainy. Comparing the annual temperatures for the last 12 years, it is seen that the years 1887 to 1891 were very cold and 1893 was very warm. Since then the curve has declined. The relation which seems to exist between the temperature and the sun spots has already been pointed out.

TEMPERATURE AT AND BELOW THE SURFACE OF THE SOIL
COVERED WITH GRASS.

The temperature of the interior of the soil plays an important part in the phenomena of plant growth. It affects a large number of food plants which are produced under the surface as well as the roots of the trees, which develop at various depths. One of the first duties of the climatological station of Juvisy was the construction of thermometers, registering instruments, etc., to be placed at various depths under the surface of the soil to register the variations in temperature. The temperature was recorded by an apparatus one meter above the soil, which could be read and compared constantly. Five thermometers composed of metallic cylinders filled with spirits of wine were placed at depths of 0.05, 0.10, 0.25, 0.50, and 1 meter, to constantly register the temperature. The comparison of daily curves gives results which are curious as well as important. Thus it can be seen that the amplitude of the curve varies with the depth, being very large at 0.05 and nothing at 1 meter. The following table shows the monthly average temperature observed at the surface of the soil and at different depths in 1896:

Average temperature of soil and air at Juvisy during 1896.

Month.	In the air.	At surface of ground.	Below the surface of the ground.				
			0.05 meter.	0.10 meter.	0.25 meter.	0.50 meter.	1 meter.

Average.....	9.80	12.78	11.75	11.35	11.69	11.91	12.61

Figure 7 gives a graphic representation of the temperature at different depths. Temperature affects plants differently according to the depth of their roots. At 0.05 meter, for instance, is given the temperature for the germination of seed. The maximum, and especially the minimum, temperatures are most important. The highest average temperatures in winter were those at a depth of 1 meter, while in summer the highest temperatures were at the surface of the soil and the lowest at a depth of 1 meter. There is an inversion in the spring and in the autumn.

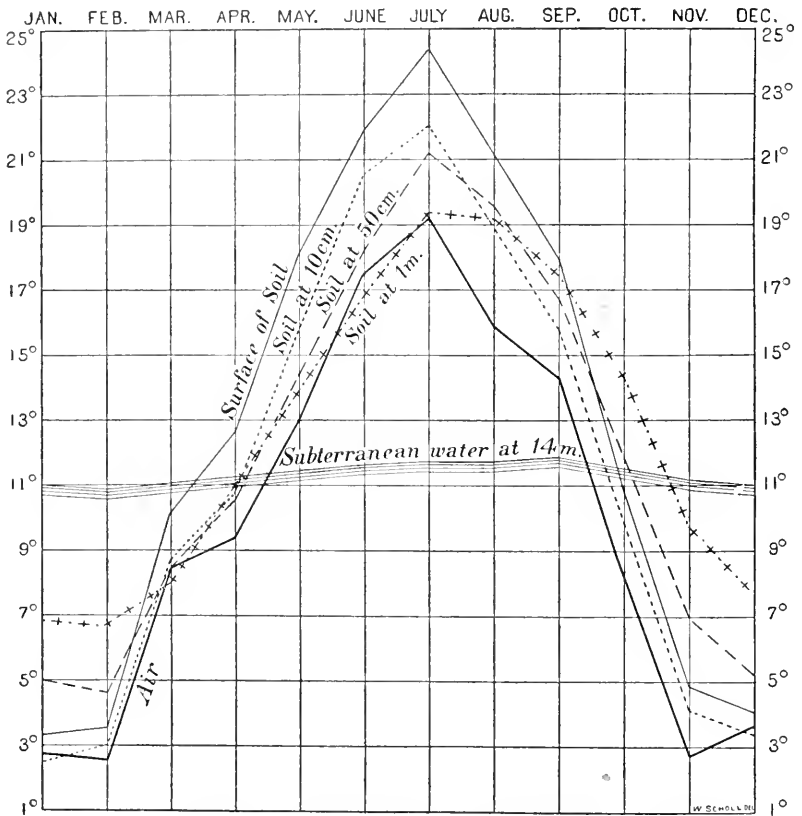

FIG. 7.—Temperature of subterranean water and of the soil at different depths.

On this account the average annual temperature is about the same for all the depths. These phenomena vary somewhat from one year to another, the inversions being produced more or less slowly according to the heating or cooling of the soil. At times this inversion is remarkable, as was the case in the spring of 1896. Sometimes it is very incomplete, as in the winter of 1896. The minimum was observed in February and the highest temperature was attained in July. Hot days completely dry out the superficial layers of the soil, and high temperatures are, unless accompanied by a sufficient rainfall, injurious to plants.

May and June were hot and dry, and plants did not get the necessary moisture. If the average annual temperatures of the soil at different depths are compared, it will be seen that the temperatures diminish from the surface of the soil as far down as 0.10 meter, where it reaches a minimum, from which it rises as far as 1 meter. The increase in temperature is less rapid from 0.10 to 1 meter than the decrease from the surface of the soil to 0.10 meter. This phenomena, which at first might appear abnormal, is easily explained. The sun's heat is transmitted through the soil by conductivity. The heating of the soil is either effected through the contact with the warmer air or by the direct action of the sun's rays. The heat is transmitted to the different depths by warming successively the different layers of the soil. The cooling is effected by contact with the colder air, and also by the radiation. The layers of the soil cool from the surface toward the interior, and there is a certain depth where the temperature reaches a minimum. This depth where the temperature is lowest varies according to the different meteorological conditions during the day. The annual average is 0.10 meter below the surface. Wind, rain, and the condition and the humidity of the soil are factors which influence heat and cold. These agents influence specially the superficial layer of the soil and modify its temperature. It is not possible therefore to state with any precision whether the soil is warmer or colder at this or that depth. The fluctuation of the temperature of the soil at different depths is shown in the following table:

Variation in temperature of soil at different depths.

Date.	In the air.	At surface of ground.	Below the surface of the ground.				
			0.05 meter.	0.10 meter.	0.25 meter.	0.50 meter.	1 meter.
	Deg. C.	Deg. C.	Deg. C.	Deg. C.	Deg. C.	Deg. C.	Deg. C.
August 4.....	18.1	26.7	22.5	22.5	22.4	21.0	19.5
5.....	16.8	25.5	22.5	22.2	23.1	21.0	19.6
6.....	15.1	20.7	19.7	19.9	21.3	20.7	19.6
7.....	14.3	19.5	18.1	18.2	19.8	20.4	19.6
8.....	14.8	18.0	17.8	17.6	18.8	20.0	19.5
9.....	15.1	18.6	18.1	17.8	19.2	19.5	19.5
10.....	15.4	19.2	18.1	17.8	18.8	19.1	19.2
11.....	17.0	22.2	20.0	19.4	19.6	18.7	19.0
12.....	17.8	22.9	21.0	20.4	20.5	20.3	19.0
13.....	17.5	22.7	21.3	20.2	20.7	20.6	19.0
14.....	16.5	23.6	20.7	19.9	20.5	19.6	19.0

On August 4 the temperature of the soil was the same at 0.05, 0.10, and 0.25 meter below the surface, but it was considerably modified the next day. August 8 the temperature at 0.10 meter was lower than at 0.05 and higher at 0.25 than at 0.05. At this time there was a general cooling off, which acted rapidly on the superficial layers as far as 0.10, but it was of little effect at the lower depths. Other modifications followed, and the rise and fall of temperatures at different depths were according to the rapidity and the duration of the atmospheric changes. The temperature of the soil follows that of the air, but it gives better

and more precise indications in regard to the life of the plants. It is considered preferable to take the temperature of the soil, which shows the intensity and the variation of the solar radiation, as well as indicates the quantity of heat received during the day and the amount lost by radiation.

RAINFALL

The monthly rainfall collected by the two pluviometers for 1896 was as follows:

Rainfall during 1896, by months.

Month.	Rainfall.	Month.	Rainfall.
	<i>Mm.</i>		<i>Mm.</i>
January	18.0	August	36.8
February	4.9	September	140.6
March	51.9	October	154.0
April	18.2	November	50.1
May	3.2	December	77.7
June	83.1		
July	28.5	Total	667.0

In 1893 the precipitation was 526 mm.; in 1894, 503.4 mm.; in 1895, 493 mm. In 1896 the first part of the year was dry, followed in the summer and autumn by cyclones, storms, and waterspouts, which are

FIG. 8.—Annual rainfall at Paris since 1689.

very unusual in France. The rainfall in September was 140.6 mm.; in October, 154.1 mm., an amount not exceeded since 1689, when the first observations were recorded. On account of the continued rains, which were remarkable for the region, the author conceived the idea of comparing the results of all the observations made at Paris since the foundation of the observatory. The first pluviometer was installed on the terrace of the observatory in Paris in 1688, and regular measurements of the rainfall were made from January, 1689, to December 31, 1754,

except during 1698. Other periods of observations extended from 1773 to 1797 and from 1804 to 1872. After January 1, 1873, the observations were made at Montsouris, 3 kilometers south of the observatory of Paris. The conditions at each place are nearly the same. In fig. 8 the rainfall is represented by vertical lines, the height of which corresponds to the quantity of water which fell at Paris from 1689 to 1896, except during the three intervals already mentioned. The diagram is interesting, not only as an exact record, but because it indicates the gradual increase in the rainfall of Paris for the last 200 years. This increase can be seen in the accompanying table, where the averages are given for certain periods:

Annual rainfall at Paris since the year 1689.

Year.	Rainfall.	Year.	Rainfall.
	<i>Mm.</i>		<i>Mm.</i>
1689 to 1719	485.7	1825 to 1844	507.5
1720 to 1754	409.4	1845 to 1872	522.4
1773 to 1797	492.5	1873 to 1896	557.4
1804 to 1824	503.7		

It appears that the rainfall in Paris has increased from period to period, or that the older observations were not carefully made at the observatory at Paris.

The condition of the sky during the 24 hours of each day for the year 1896 was noted as follows:

Condition of the sky during the year 1896.

Designation.	Jan.	Feb.	Mar.	Apr.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Clear	2	3	0	1	6	1	2	0	0	1	2	0
Somewhat cloudy	0	3	4	1	15	8	9	7	5	2	4	0
Cloudy	4	7	6	15	5	9	7	11	5	9	7	3
Very cloudy	7	8	13	10	5	11	12	10	17	13	9	11
Covered	18	8	8	3	0	1	1	3	3	6	8	17
Total	31	29	31	30	31	30	31	31	30	31	30	31
Number of rainy days.....	3	6	18	9	5	11	9	6	19	20	5	15

It is seen that the cloudiness was very great during the year. The sky was beautiful in May but almost entirely overcast during January and December. There was on an average one rainy day to two days without it, and during 202 days the sky was completely overcast or very cloudy.

SUBTERRANEAN WATERS.

The thickness of the water sheets of wells and the temperature of these waters have important climatological bearing. Observations were continued on two wells, the first 13.56 meters and the second 14.08 meters deep. The temperature of the water in each well was as follows:

Temperature of water in two wells at Jurisy.

Month.	Well A.	Well B.	Average.
	<i>Deg. C.</i>	<i>Deg. C.</i>	<i>Deg. C.</i>
January.....	11.3	10.8	11.0
February.....	11.2	10.7	10.9
March.....	11.2	10.8	11.0
April.....	11.4	10.9	11.2
May.....	11.4	11.3	11.4
June.....	11.8	11.4	11.6
July.....	11.9	11.4	11.7
August.....	11.8	11.6	11.7
September.....	11.8	11.8	11.8
October.....	11.5	11.2	11.4
November.....	11.3	10.8	11.1
December.....	11.1	10.9	11.0
Annual average.....	11.47	11.14	11.32

We have here two different sheets of water which, notwithstanding their proximity and almost equal depth, have not exactly the same temperature, it being a little higher in well A (the more shallow one), the difference varying from 0.2 to 0.9°. These sheets differ also chemically. The water in well B is less potable and contains more lime. The annual difference of temperature of the two wells averages 0.33°.

The average temperature of air, soil, and water for 1896 was as follows: Air, 9.80°; at the surface of the soil, 12.78°; the soil at a depth of 0.10 meter, 11.35°; at a depth of 0.50 meter, 11.91°; at a depth of 1 meter, 12.61°; water at a depth of 14 meters, 11.32°. The temperature of the waters of the two different wells varies but little in the course of the year, the cold of winter and the heat of summer being slightly felt.

ACTION OF ELECTRICITY UPON PLANT GROWTH.

The question of the influence of electricity on plants has been the subject of much discussion during the last few years. The results obtained from experience were frequently contradictory. For this reason some experiments were conducted in which copper and zinc plates of 0.70 meter length and 0.45 meter width, bent at right angles, were placed at the extremities of a plate 2 meters wide and 4 meters long and stuck into the ground, the top being a little above the surface. The plates were joined by insulated copper wires. There were thus created zinc-soil-copper piles on which it is supposed that an electric current could be established. The current was rendered more active by adding a Le Clanché pile of three elements and its influence on the germination of seeds tested. August 31, 1894, 56 beans were put in rows on each plate. The current was passed through for ten hours. After this an interrupted current, sometimes during the night and sometimes during the day, was passed through the apparatus. The results are worthy the attention, as the evidence of an electric action is positive.

Effect of electricity on the germination of beans.

Date.	Number of grains germinating.	
	Electric band.	Non-electrified.
September 4.....	4	0
5.....	16	2
10.....	54	34
11.....	54	40
13.....	56	45

This experiment shows that the germination was more rapid in the electrified seed and also that a greater number had germinated. We repeated the experiments in 1895 and 1896 on peas and beans with the following results: May 11, 1895, the same number of seeds were placed in each plate. No difference could be seen during the time of germination. The peas bloomed June 16; the flowers at that time were more numerous and the plants better developed in the electrified plates than in those without. The beans bloomed July 2 over all the plates. The growth of the beans was better in the electrified portion. The peas were gathered twice and gave the following results: Average of electrified portions, 941 gm.; check, 820 gm. Part of the beans were gathered twice and yielded: Electrified, 2,900 gm.; check, 2,250 gm. For the other parts there was but one harvest, which yielded as an average for the electrified portions 1,410 gm., and check, 1,445 gm. One of the electrified portions gave a yield of 375 gm. less than the check. The results of these experiments show that the parts electrified by piles yielded a harvest from 20 to 28 per cent greater than the natural one.

OBSERVATIONS ON TREE TEMPERATURES.

To solve some of the questions relative to tree temperatures, elbow-thermometers were constructed, the bulbs of which were inserted in the heart of the tree. Numerous observations made in 1894, 1895, and 1896 permit the following statements: The internal temperature of trees follows that of the air. The temperature of the air is led into the interior parts, and this transmission is more or less rapid according to the diameter of the tree and the conditions of the tissues. The temperature varies with the diameter of trees of the same species and exposure. In conclusion, conductivity differs according to species. The sudden variations of the temperature in the interior of the trees are avoided by the modification of the sun.

The foregoing are summarized statements of the researches which have been made at the agricultural-climatologic station at the observatory of Juvisy. The author believes that much remains to be discovered in the lines indicated.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Legumin and other proteids of the pea, lentil, horse bean, and vetch, T. B. OSBORNE and G. F. CAMPBELL (*Connecticut State Sta. Rpt. 1897, pp. 321-373*).—The authors give in detail the methods and results of extensive investigations on the proteids of these seeds. They find that they all contain legumin, legumelin, and proteose, and that in addition the seeds of the pea, lentil, and horse bean contain vicilin. No difference was found in the reactions and properties of preparations of each of these proteids from the different seeds.

The results of the investigation are summarized as follows:

“*Legumin*.—Legumin forms the chief proteid constituent obtainable from the vetch, pea, lentil, and horse bean. In the first-named seed about 10 per cent of the meal was found to consist of legumin; in the three other seeds this proteid is associated with vicilin, from which we have no method for its quantitative separation. From the pea about 10 per cent, from the lentil 13 per cent, and from the horse bean about 17 per cent of these mixed proteids were obtained. The lentil contains the least proportion of legumin, which seems to form about two-thirds of the mixed proteids, while the horse bean contains the greatest, as in this seed vicilin is present in relatively small amount.

“Legumin is a globulin, for it dissolves readily in saline solutions and is precipitated therefrom either by dialysis, dilution, or cooling. By dialysis or by cooling it separates in the form of spheroids, which, after settling from the solution, unite to form a plastic mass. By diluting its concentrated solutions the legumin separates as a viscid translucent fluid. This fluid when treated with water becomes opaque and solid, so that the legumin can be converted into a coarse meal by rubbing with a glass rod under water. Conglutin from lupine seeds and amandin from almonds behave similarly, as do gliadin of wheat and rye and hordein of barley when precipitated from alcoholic solutions by dilution with water.

“Solutions containing more than 2 per cent of sodium chlorid dissolve legumin abundantly, those containing less salt have a solvent power rapidly decreasing with the diminishing salt content, so that a 1 per cent salt solution dissolves very little. Saturation with sodium chlorid or magnesium sulphate does not precipitate legumin from its solution in brine, but saturation with sodium sulphate at 34° precipitates it almost completely.

“In pure water legumin is entirely insoluble, but if the solution from which the legumin is precipitated contains acid, this may combine with the legumin and the resulting preparation, like other acid globulins, will then dissolve in pure water.

“If seeds containing legumin are extracted with water, more or less of the legumin is dissolved; from the pea about 4 per cent, from the vetch 2.5 per cent, from the lentil 10 per cent, and from the horse bean 16 per cent. The legumin thus dissolved is largely precipitated by dialysis in water, by the addition of acids and by lime salts, and very slightly by great dilution with water. These aqueous

extracts react strongly acid with litmus, and alkaline with laemoid, a behavior doubtless due to acid potassium phosphates together with organic acids or acid salts. . . .

"In consequence of the varying proportions of these substances in the different kinds of seeds, different amounts of legumin are thus extracted from them. As the proportion of phosphoric acid to potash in these leguminous seeds is much smaller than in most of the other seeds which we have examined, the character of the salts present may fairly be supposed to differ, and consequently the solubility of the proteids would also differ when the seeds are extracted with water. . . .

"Dissolved in dilute sodium chlorid solution, legumin is precipitated by a little acetic acid, the precipitate being soluble in an excess of sodium chlorid. The solubility of precipitates so produced depends on the relative proportions of salt and acid.

"Legumin extracted without neutralizing the natural acid of the seed and precipitated by dialysis, either directly or after precipitation with ammonium sulphate, is usually converted to a large extent into insoluble 'albuminate.' This 'albuminate' differs from the similar insoluble products obtained from most other globulins, for when treated with salt solution it becomes gelatinous, can not be filtered, and on washing with water shrinks, becomes opaque, and finally granular so that it can be very readily washed on a filter. This substance appears to become hydrated by salt solution and dehydrated by pure water.

"If the acid of the seed is previously neutralized, the globulin extracted by salt solution yields very little if any insoluble 'albuminate,' which indicates that the latter is a product of the action of the acid of the seed. This fact is in harmony with experiments described in a former paper of ours on the action of minute quantities of acid on globulins.¹ In very dilute acids and alkalies in the absence of salts, legumin dissolves readily and abundantly to solutions from which, if at once neutralized, it is precipitated in a form soluble in sodium chlorid solution. By this treatment no evidence of change has been detected. Solutions made with hydrochloric acid are precipitated by a small excess of acid, but those made with acetic acid are not precipitated by any excess of acid.

"Solutions of legumin in 10 per cent sodium chlorid brine are not rendered turbid by long heating in a boiling water bath.

"Dissolved in 10 per cent sodium chlorid brine, legumin is precipitated by a very little hydrochloric acid, but a relatively considerable amount of acetic acid is required to produce a precipitate in such solutions.

"Sodium chlorid solutions of legumin give large precipitates with tannic acid as well as with picric acid, those formed by the latter dissolving in an excess of salt solution if too much picric acid had not been previously added. With mercuric chlorid no precipitate is produced.

"With nitric acid, Millon's and Adamkiewics' tests, proteid reactions are obtained. With the biuret test a violet color is given, which on standing becomes a deep rose red, like that given by peptones.

"Legumin has been supposed by some investigators to contain phosphorus, and therefore to belong with the nucleo-proteids. A careful testing of thoroughly purified samples by fusing with caustic soda and nitrate, and treating the solution of the fusion acidified with nitric acid, with ammonium molybdate, showed that in some of the preparations only just detectable traces of phosphorus were present, while other preparations contained none whatever.

"Although we have examined large numbers of our preparations of the different plant proteids for phosphorus, we have as yet found none which, in carefully purified samples, contained more than a few hundredths of a per cent of phosphorus; a quantity so small that it is reasonable to consider it as a constituent of the ever-present ash.

¹ Connecticut State Sta. Rpt. 1896, p. 369 (E. S. R., 9, p. 515).

“The composition of legumin is shown by the following figures, which, except those for the pea, are averages of a number of preparations from each of the different seeds:

Composition of legumin from different seeds.

	Pea.	Lentil.	Horse bean.	Vetch.	Average.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Carbon.....	51.74	51.73	51.72	51.69	51.72
Hydrogen.....	6.90	6.89	7.01	6.99	6.95
Nitrogen.....	18.04	18.06	18.06	18.02	18.04
Sulphur.....	.42	.39	.39	.43	.41
Oxygen.....	22.90	22.92	22.82	22.87	22.88
Total.....	100.00	100.00	100.00	100.00	100.00

Vicilin.—Vicilin is a globulin associated with legumin in the pea, lentil, and horse bean. But as we have no means of separating vicilin and legumin quantitatively, we can state nothing respecting the amount in which it occurs in these seeds further than that the lentil contains the most and the horse bean the least. In the lentil it probably forms about one-third of the mixed globulins. That vicilin is not a derivative of legumin is almost conclusively proved by the fact that no vicilin can be obtained from the vetch.

“The most remarkable characteristic of vicilin is its content of sulphur, less than that of any other known proteid. This element, it may be noticed, diminishes in quantity with repeated precipitation. . . .

“It would seem possible by sufficiently repeated precipitation to obtain from this proteid preparations free from sulphur.

“In salt solution, vicilin is much more soluble than legumin, so that by repeated precipitation from diluted solutions the two globulins can be separated.

“When solutions of vicilin in 10 per cent brine are heated in a water bath they become turbid at 90° and at 95° flocks separate. When heated for some time at 100° this globulin is almost completely coagulated. In water vicilin is insoluble. In 1 per cent sodium chlorid solution it dissolves considerably, while in slightly stronger solutions it is much more soluble, the solution of the globulin appearing to depend on the presence of enough salt to form a soluble compound.

“In its other reactions it very closely resembles legumin.

“The composition of vicilin we found to be as follows:

Composition of vicilin from different seeds.

	Pea.	Lentil.	Horse bean.	Average.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Carbon.....	52.36	52.13	52.38	52.29
Hydrogen.....	7.03	7.02	7.04	7.03
Nitrogen.....	17.40	17.38	17.52	17.43
Sulphur.....	.18	.17	.15	.17
Oxygen.....	23.03	23.30	22.91	23.08
Total.....	100.00	100.00	100.00	100.00

Legumelin.—We have found legumelin in all the leguminous seeds which we have examined, with the exception of the white bean (*Phaseolus vulgaris*) and the blue and yellow lupines.

“It is difficult to decide whether this proteid should be considered an albumin or a globulin. . . . We now consider legumelin to be more properly classed with the albumins.

“The amount of legumelin which we have found in the seeds discussed in this paper was in the pea 2 per cent, vetch 1.5 per cent, lentil and horse bean 1.25 per cent.

“No definite coagulation point can be stated for legumelin, for the presence of

"46. Precipitated by saturating with salt and adding acetic acid.

"47. From the filtrate from 46.

"68. Total proteose precipitated by alcohol.

"89. Ditto.

"98. Precipitated from salt saturated solution by acetic acid.

"22. Total proteose precipitated by alcohol

"If the difficulty encountered in purifying these preparations of proteose and the different methods by which they have been obtained are considered, the agreement between them, except for the sulphur in those from the horse bean, makes it probable that these figures quite nearly represent the composition of this substance."

Proteids of the soy bean, T. B. OSBORNE and G. F. CAMPBELL (*Connecticut State Sta. Rpt. 1897, pp. 374-382*).—The seeds of 2 varieties were studied, the yellow soy bean and the variety known in Japan as kiyusuki diadzu. From the results of the investigations, which are given in detail, the author deduces the following conclusions:

"The soy bean contains as its chief proteid constituent glycinin, a globulin similar in properties to legumin, but of somewhat different composition, containing nearly twice as much sulphur, 0.4 per cent more carbon, and 0.5 per cent less nitrogen.

"We give as the composition of this proteid the results of our analysis of preparation 9, which was obtained from a neutral and perfectly clear extract, for we believe that this represents more accurately the true composition of glycinin than the average of all the preparations: Carbon, 52.12; hydrogen, 6.93; nitrogen, 17.53; sulphur, 0.79; oxygen, 22.63 per cent.

"The soy bean contains a more soluble globulin which resembles phaseolin in composition, and, so far as we could ascertain, also in its reactions. The amount of this proteid is small and the evidence that it is in reality phaseolin was not wholly satisfactory.

"Besides these globulins about 1.5 per cent of the albumin-like proteid legumelin was obtained. We have found legumelin in a number of other leguminous seeds, the pea, vetch, horse bean, lentil, adzuki bean and cowpea. The properties of legumelin are given in our paper [noted above]. The composition of legumelin as found in the soy bean is as follows: Carbon, 53.06; hydrogen, 6.94; nitrogen, 16.14; sulphur, 1.17; oxygen, 22.69 per cent.

"A small quantity of proteose was also obtained from the soy bean, having the following composition: Carbon, 48.76; hydrogen, 6.28; nitrogen, 16.14; sulphur and oxygen, 28.82 per cent.

"Owing to the small amount of proteose no evidence was obtained as to the purity or individuality of this preparation."

On the solubility of tricalcium phosphate and apatite in water, J. JOFFRE (*Bul. Soc. Chim. Paris, 3. ser., 19 (1898), No. 9, pp. 372-375*).—Tricalcium phosphate was subjected to the action of water for two months. The solution obtained was filtered, evaporated to dryness, and phosphoric acid determined in the residue. The solubility of the phosphate was found to be 0.009 gm. per liter of water. When the phosphate was subjected to the action of water charged with carbon dioxid for the same length of time the solubility was found to be 0.153 gm. per liter. Apatite treated in the same way showed a solubility in pure water of 0.002 gm. per liter; in water saturated with carbon dioxid 0.014 gm. per liter. It is thus seen that the apatite is much less soluble than tricalcium phosphate. Monocalcium phosphate was mixed with carbonate of lime. After three or four days the phosphoric acid

soluble in water was extracted and the residue treated with a large quantity of water charged with carbon dioxid. By this means 0.161 gm. of tricalcium phosphate per liter was dissolved from the residue insoluble in water, an amount very nearly identical with that dissolved by treating tricalcium phosphate in the same way.

These results indicate that when superphosphates are applied to the soil, although a large part of the soluble phosphoric acid is converted into the tricalcium form, it is so uniformly distributed throughout the soil that it is readily dissolved by the carbon dioxid present in the soil or by the acids secreted by the roots of plants.

A method for distinguishing bone phosphate from mineral phosphate, F. MARTINOTTI (*Stat. Sper. Agr. Ital.*, 30 (1897), No. 8, pp. 663-668).—The method is based upon the difference in silica content of the different kinds of phosphates. The silica is removed before the determination of phosphoric acid by evaporating the acid solutions to dryness. In the large series of analyses reported the smallest amount of silica found in mineral phosphates was 5.25 per cent, while the greatest amount found in bone phosphates was 0.9 per cent. In bone ash as high as 3 per cent of silica was found. In superphosphates prepared from mineral phosphates the minimum amount of silica was 1.2 per cent. In case of bone ash superphosphates the maximum silica content was 0.8 per cent. Double superphosphates were found to contain about 3 per cent of silica. In a mixture of bone superphosphate and mineral superphosphate the smallest amount of silica found was 2.26 per cent.

From his investigations the author draws the conclusions that (1) mineral phosphates can be distinguished from bone phosphates by the relative quantities of silica which they contain; and (2) bone phosphates and bone superphosphates that contain more than from 0.8 to 1 per cent of silica are adulterated with mineral phosphates and mineral superphosphates.

Proteids of the soy bean, T. B. OSBORNE and G. F. CAMPBELL (*Jour. Amer. Chem. Soc.*, 20 (1898), No. 6, pp. 419-428).—Reprinted from Connecticut State Station Report for 1897 (see p. 218).

BOTANY.

Investigations on the native vegetation of alkali lands, J. B. DAVY (*California Sta. Rpt. 1895-1897, pp. 53-75, pls. 8, fig. 1*).—The object of this investigation was to ascertain if possible whether the characteristic plants of alkali plats would indicate the kind of alkali present and the degree of its impregnation, so as to enable any one to determine the possibility of reclamation without reference to the station.

An introductory note by E. W. Hilgard reviews the previous investigations of the station regarding alkali lands which, summed up, shows that the salts found impregnating alkali lands consist in the main of varying proportions of sodium sulphate, sodium carbonate, and common salt. The total content of this mixture varies from a small fraction of 1 per cent to more than 12 per cent of the total weight of the soil taken to a depth of 4 ft. Of the three compounds named, sodium carbonate, or black alkali, is the most injurious to vegetable growth and to the tilling qualities of the soil. In reclaiming alkali lands for cultural purposes the first thing necessary is a transformation of the carbonate into sulphate of soda by the addition of gypsum. In addition to the salts already mentioned other alkalies are found in varying proportions, but as most of these are in the form of soluble plant food they are available for plant growth as soon as the injurious effects of the surplus of other constituents is removed.

The resistance or tolerance of the several salts by plants varies greatly for the different plants and for the different salts. Thus chenopodiaceous plants are in general very resistant, while, on the other hand, leguminous plants resent even small quantities of any of the injurious alkalies. The Compositæ are rather tolerant of alkali, while most cultivated grasses are sensitive to it.

With a few exceptional cases, the investigations of the station have shown that the bulk of the salts in alkali lands may at all times be found within about 4 ft. of the surface, and sometimes, as during a very dry season, they may accumulate almost wholly within 6 in. of the surface. Upon the basis of these facts it is thought an estimate of the aggregate amount of alkali liable to influence vegetable growth on any land can be made and the methods of reclamation determined. This might be determined by chemical analysis of the soil, but to avoid this expense to the landowners a simpler method was sought, a preliminary summary of which is given in the report. The author collected samples of alkali soils upon which various plants grew at a number of places, and these samples, 58 in number, were analyzed and are reported upon by the agricultural chemist, R. H. Loughridge.

In studying the natural vegetation of alkali lands the author made several visits to parts of California that are noted for their alkali soils, and in addition to the soil samples taken collected over 1,500 sheets of

botanical specimens, a number of samples of water, and native seeds, roots, etc.

From a careful study of the plants collected it was found that most of them were confined to particular soils, at least when in the wild state. These plants are therefore designated as characteristic alkali plants, the most conspicuous of which are *Sesuvium*, samphire, saltwort, *Kochia californica*, yerba mansa (*Anemopsis californica*), *Nitropila occidentalis*, tall tar weed (*Centromadia pungens*), several species of *Atriplex*, alkali heath (*Frankenia grandifolia campestris*), tussock grass, salt grass, fine top salt grass (*Sporobolus asperifolius*), bushy golden-rod, grease wood (*Allenrolfea occidentalis*), and several species of Tissa. In addition to these were found a number of introduced plants which occur as weeds and which tolerate the abnormal conditions of soil and climate. Among these are the common sunflower, sow thistle, mallow, bitter melilot, plantain, Bermuda grass, and *Erigeron canadensis*. In all there are known to be at least 197 species of plants natives of California which are restricted to alkali soils.

One of the striking features of the alkali plats is said to be the gregarious nature of the plants found upon them. Some species are rare and may be described as local, while others occur in distinct belts or zones of vegetation forming the principal and often exclusive vegetation over large areas, while at least two species, salt grass and alkali heath, may be called cosmopolitan.

Particular studies were made of the different belts or zones as indicated by the plant growth, and samples of soil in these characteristic belts were collected and analyzed. The minimum and maximum of alkali salts tolerated by each plant are given, although the figures are not necessarily from one and the same soil. The observations and analyses when summarized show among other results the following:

Pounds of alkali per acre in one foot of soil from the different belts.

Belts.	Sulphates.		Carbonates.		Chlorids.		Total salts.	
	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.
Scrub saltbush (<i>Atriplex poly-</i> <i>carpa</i>)	Trace.	37,880	240	19,000	None.	21,360	840	78,240
Bushy Golden-rod (<i>Bigetovia ve-</i> <i>vela</i>)	680	15,360	None.	7,480	None.	3,720	1,800	24,320
Saltwort (<i>Sueda</i> sp.)	36,000	176,000	360	24,240	26,000	105,800	74,480	306,040
Tussock grass (<i>Sporobolus air-</i> <i>oides</i>)	3,440	98,920	680	13,480	360	55,680	6,600	155,280
Grease wood (<i>Allenrolfea occi-</i> <i>dentalis</i>)	7,440	146,000	160	3,400	10,400	85,880	27,320	194,760
Samphire (<i>Salicornia</i> sp.)	55,320	176,000	320	24,240	5,560	105,800	61,240	306,040

The last two belts indicated in the table contain such a large amount of injurious salts as to seem incapable of profitable reclamation. Of the belt characterized as the tussock-grass belt, while the total content of alkali in the soil is high, the grass, which grows abundantly, is said

to be readily eaten by stock, and further investigations are desired relative to its adaptation and possible use.

Summing up the results as far as possible, the distribution of plants in belts or zones is believed to be due to physical and chemical conditions of the soil, and these plants may be used as indicators of soil conditions. The Biglowia and scrub saltbush indicate, from the data at hand, a light gravelly soil with apparently a low alkali content chiefly composed of sulphates. The minimum of sulphates is least and the maximum highest in the scrub saltbush belt, but black alkali and chlorids are least in the Biglowia belt. Samphire indicates a moist soil with excessive chlorids and sulphates. Grease wood, so far as determined, occurs only in a moist soil where sulphates and common salt are heavy and carbonates light. Saltwort depends on heavy chlorids and heavier chlorates with carbonates varying between 360 and 24,000 lbs. per acre. The full extent of the value of these and other plants as alkali indicators can not yet be determined.

The author suggests quite a number of plants that may be cultivated on alkali soils. Among these are the saltbushes, samphire, sugar beet, spinach, mangel-wurzel, *Chenopodia quinoa*, Australian saltbushes, etc. Sunflowers are reported growing wild on a soil which contains 9,820 lbs. sulphates, 1,400 lbs. carbonates, 920 lbs. chlorids, and 1,440 lbs. nitrates in the first foot of soil. Other plants belonging to this same family which grow wild on moderately alkali lands are the Jerusalem artichoke, oyster plant, chicory, true artichoke (*Cynara scolymus*). Valuable fodder plants which are known to grow on decidedly alkaline soils are mentioned, among the more promising of which are *Modiola decumbens*, quack grass, tussock grass (*Sporobolus airoides*), and water grass (*Beckmania eruciformis*). In conclusion the author gives a preliminary list of plants suitable for cultivation on alkali soils, dividing them into those which are adapted to strong alkali and those which are not tolerant of the strongest alkali. The list is as follows:

On strong alkali.—Saltbushes, modiola, wild millet or water grass, *Kolreuteria paniculata*, sac-saoul (*Haloxylon ammodendron*), *Salsola soda*, and *S. indica*, and kochia (*Kochia* spp.).

Apparently not tolerant of the strongest alkali.—Sunflower, Jerusalem artichoke, beets, spinach, onion, celery, asparagus, *Elaeagnus angustifolius*, and the Peruvian ground cherry (*Physalis peruviana*).

Fodder plants.—Slender grass (*Leptochloa imbricata*), Johnson grass, quack grass, tall smooth panic grass (*Panicum virgatum*), smooth bunch grass (*Atropis larvis* and *A. californica*), obtuse meadow grass (*Eragrostis obtusiflora*), wild rye (*Elymus condensatus*), alkali saccatone (*Panicum bulbosum*), fiorin, Bermuda grass, jointed barley grass, tea tree, and myall (*Acacia* spp.).

Investigations on various economic plants, J. B. DAVY (California Sta. Rpt. 1895-1897, pp. 265-270).—This is the report of the assistant botanist. Among other economic notes the author suggests as bee plants for late winter and early spring in California the follow-

ing: Tagasaste (*Cytisus proliferus albus*), *C. canariensis*, borage (*Borago officinalis*), honey flower (*Melianthus major*), and *Colletia ephedra*.

Brief notes are given on several forage plants which seem promising for different parts of the State. *Aristida oligantha* is considered an excellent grass, and what, from an incomplete specimen, appears to be *Bromus sterilis* is also considered promising for the sage-brush lands in certain parts of the State.

Notes are given on several weeds and on an unidentified fiber plant said to occur very abundantly in Monterey County. The latter will be further investigated.

Suggestions are made for tree planting in the streets around San Francisco Bay. Numerous trees are suggested and described.

Investigations concerning chlorophyll, G. BODE (Inaug. Diss., Jena, 1898).

Concerning protoplasm and active albumen, O. LOEW (Bot. Centbl., 74 (1898), No. 1, pp. 5-13).

On the reaction of protoplasm to thermal stimuli, K. L. SCHAEFER (Flora, 85 (1898), No. 2, pp. 135-140).

Researches on the presence of hydrocyanic acid in different plants, A. HÉBERT (Bul. Soc. Chim. Paris, 3. ser., 19 (1898), No. 7, pp. 310-313).

Concerning proteid formation in plants, W. ZALESKI (Ber. Deut. Bot. Gesell., 15 (1897), No. 10, pp. 536-542).

A compendium of botany, T. BOKORNY (Lehrbuch der Botanik. Leipzig, 1898, pp. VI + 226, figs. 170).

FERMENTATION—BACTERIOLOGY.

Spore formation among Russian wine yeasts, A. NASTUKOFF (*Centbl. Bakt. u. Par.*, 2. *Abl.*, 4 (1898), No. 10, pp. 420, 421).—Out of 35 specimens of yeasts studied 15 formed spores at 25° C. in 48 hours and 13 at 15° C. in 72 hours.

On the question of alcoholic fermentation without living yeast cells, M. VON MANASSEIN (*Ber. Deut. Chem. Gesell.*, 30 (1898), No. 19, pp. 3061, 3062).

On some micro-organisms of wine, F. BORDAS, JOULIN, and DE RACZKOWSKI (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 14, pp. 1050-1053).

Introduction to the study of bacteriology with special reference to microscopical technique (*Einführung in das Studium der Bakteriologie mit besonderer Berücksichtigung der Mikroskopischen Technik*. Leipzig: Geo. Thieme, 1898, 5. ed., pp. VIII + 631, pls. 90).

On the biology of bacteria, G. SCHLATER (*Biol. Centbl.*, 17 (1897), No. 2, pp. 833-846; *abs. in Bot. Centbl.*, 74 (1898), No. 1, pp. 17, 18).

Concerning the biology of *Bacillus baccharinii*, L. MACCHIATI (*Centbl. Bakt. u. Par.*, 2. *Abl.*, 4 (1898), No. 8, pp. 332-340).—The author gives a sketch of the biology of the organism which is said to be the cause of "mal nero" or the bacterial gummosis of grapes.

Concerning the species of acetic bacteria, M. W. BELJERINCK (*Centbl. Bakt. u. Par.*, 2. *Abl.*, 4 (1898), No. 6, pp. 209-216).

Concerning the occurrence of *Bacillus baccharinii*, especially of the tubercle bacteria in living plant tissues, O. ZINSSER (*Inaug. Diss.*, Leipzig, 1897, pp. 30; *Bot. Centbl.*, *Beihfte*, 7 (1898), No. 5, pp. 337-339).

New methods of bacterial investigation, N. J. C. MÜLLER (*Neue Methoden der Bakterienforschung*. Sep. Abdr. Beitrag. Wiss. Bot., pt. 2, pp. 97-176, pls. 20. Stuttgart: E. Nägele, 1898).

METEOROLOGY.

Meteorological observations, A. O. LEUSCHNER and C. H. SHINN (*California Sta. Rpt.* 1895-1897, pp. 304-306, 326-328, 330-332, 352, 353, 365-367, 414, 415).—The data reported include a synopsis of observations at Berkeley during 10 years (June 30, 1887, to June 30, 1897) on temperature, pressure, humidity, precipitation, and direction of the wind; at the Footbill Substation on seasonal rainfall (1889-1896), mean monthly rainfall (1893-1896), dates of killing frosts (1893-1896), sunshine and cloudiness (October, 1894, to June, 1896), and temperature (October, 1894, to June, 1896) at two points having a difference of 180 ft. in elevation; at the Southern Coast Range Substation on the character of the seasons of 1886-1896, rainfall (October, 1895, to May, 1896), and temperature (July 1, 1895, to June 30, 1896); at the San Joaquin Valley Substation on seasonal (October to May) rainfall at Tulare (1892-1897), the average and extreme temperatures at Tulare for 20 years, and dates of frosts (1892-1896); at the Southern California Substation on temperature, precipitation, and cloudiness (July 1, 1894, to June 30, 1896); and at the Santa Monica Forestry Substation on maximum, minimum, and average temperature (July, 1893, to April, 1897), and rainfall (1893-1897).

The summaries of observations at Berkeley for the years ending June 30, 1896, and June 30, 1897, are as follows:

Meteorological summaries for 1896 and 1897.

	1896.	1897.
Pressure (inches):		
Mean	30.048	30.034
Highest	30.533 (Dec. 30)	30.399 (Jan. 2, Feb. 23)
Lowest	29.701 (Apr. 23)	29.466 (Feb. 18)
Temperature (degrees F.):		
Mean of the year	53.6	53.9
Maximum	92.5 (May 26)	91 (May 19)
Minimum	34 (Dec. 22, Mar. 3, 4)	33.7 (Nov. 27)
Precipitation (inches):		
Total rainfall	28.713	28.944
Dew and fog	0.055	0.080
Humidity (per cent):		
Mean	83.2	86.1
Maximum	98 (May 11)	99 (Oct. 5, Apr. 7, May 7)
Minimum	32 (Nov. 16)	51 (Oct. 18, 22)
Number of clear days	202	145
Number of fair days	70	106
Number of cloudy days	94	114
Number of foggy days	138	67
Number of days on which rain fell	63	71

Meteorological record for 1896 (*New York State Sta. Rpt. 1896, pp. 695-711*).—Tabulated daily and monthly summaries of observations on sunshine and temperature and a monthly summary of observations on precipitation for the period from 1882 to 1896.

The practical importance of agricultural-meteorological observations and brief instructions for carrying them out, P. I. BROUNOV (*Rpt. Met. Bureau Sci. Committee Min. Agr. and Gov. Estates. St. Petersburg, 1897, pp. 137, figs. 25; abs. in Selsk. Khoz. i Lyesov., 186 (1897), July, pp. 239, 240*).

WATER—SOILS.

Alkali and alkali soils, R. H. LOUGHRIDGE (*California Sta. Rpt. 1895-1897, pp. 38-53*).—The causes of failure of gypsum to correct alkali in certain cases are discussed. Three of the principal causes are noted: (1) Ignorance of the character of the alkali, gypsum being ineffective on white alkali; (2) the impurity of the gypsum used; (3) insufficient applications of gypsum. Theoretically the amount of gypsum applied should be about one-third more in weight than the amount of carbonate of soda present in the alkali. In experiments it was found “(1) that the amount of gypsum to be applied to alkali soils must be about double that of the carbonate of soda present; (2) that the effect is then apparent within 2 or 3 days; and (3) that the effect is probably permanent in the conversion of the carbonate of soda into the sulphate.”

The results of examinations of alkali soils used for experiments with various plants at Tulare and Southern California substations are reported in detail. From the data thus secured the following preliminary statement as to the ability of different crops to withstand the various salts contained in alkali has been prepared.

Tolerance of plants for the several salts of alkali.

	Maximum of each in pounds per acre, one foot in depth.				
	Sodium sulphate.	Sodium carbonate.	Sodium chlorid.	Sodium nitrate.	Total alkali.
GRASSES.

“Continued observation and experiments will without doubt enlarge the limits of tolerance as given in the tables. . . . The results represent the maximum amount per acre of each salt found in any soil where that particular plant was found growing, and without reference to the other salts in the same soil. Thus for the cowpea the maximum of carbonate of soda was found in one soil, that of the sulphate in another, and the chlorid in still some other soil.”

Analyses are given of a number of samples of alkali soils sent to the station for examination from different parts of the State.

A chemical study of some typical soils of the Florida peninsula, A. A. PERSONS (*Florida Sta. Bul. 43, pp. 601-714*).—The first part of the bulletin is devoted to a popular discussion of the following

topics: The development of scientific agriculture, the value of a chemical analysis, the origin of soils, the composition of soils, the inorganic soil constituents, description of the organic soil elements, distinction between nitrogen and ammonia, seaweed as a source of nitrogen, the inorganic soil elements, the effect of lime on soils, explanation of the different forms of phosphoric acid, the home manufacture of acid phosphate, the classification of soils, influence of mechanical condition on soil fertility, average weight of different types of soil, humus and its influence on soil fertility, peninsular soils deficient in humus, leguminous crops—beggard weed and velvet bean, nitrification and rotation of crops, irrigation and drainage, and effects of subsoiling.

The second part is devoted to analyses by the author and his assistant, J. P. Davies, of pine, hammock, and sand soils and subsoils, showing coarse earth, fine earth, humus, nitrogen, and moisture at 100° C., and water and organic matter and the mineral constituents in the fine earth. The principal results are given in the following table:

Important soil ingredients in the soils of the central and southern portions of the Florida peninsula.

County.	Insoluble residue.	Hu-mus.	Nitrogen.	Potas-sium oxid.	Phos-phoric acid	Calcium oxid.

Similar analyses are given of 11 samples of muck soils taken at depths of from 6 in. to 4 ft.

The analyses show that the pine, hammock, and sand soils are essen-

tially of a sandy character, and are most deficient in potash and least in phosphoric acid. Frequently they are deficient in humus.

"The muck soils of the peninsula are uniformly of a fertile character. The purest muck beds, occupying vast areas in the central and southern peninsula, extending from Osceola County southward into the Everglades, are unusually rich in nitrogen, but, in most cases, are deficient in potash, phosphoric acid, and lime. Vast tracts of this land in Osceola and Dade counties have already been drained by cutting canals through the muck beds, and are now in a high state of productiveness. Other rich muck areas lie along either bank of the Kissimmee River, which connects Lake Okeechobee with Lake Kissimmee. Still other vast muck deposits occur south of Lake Okeechobee and extend into the Everglades. In addition to the above, muck deposits of varying areas occur all over Florida.

"As a rule, the purest muck deposits contain the smallest stores of mineral plant food, but are richest in nitrogen. Many samples are reported in this bulletin, however, which are very pure mucks and which, in addition to nitrogen, contain noticeably large supplies of both phosphoric acid and lime. Only in potash do they appear to be very deficient.

"The average amounts of the several so-called essential plant foods occurring in all muck analyses reported are as follows: Nitrogen, 1.9411 per cent; potash, 0.0443 per cent; phosphoric acid, 0.0897 per cent.

"In some instances the muck soils contain excessive amounts of chlorin in the form of common salt."

Physical effects of lime on soils, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 2, 3, fig. 1*).—Series of zinc cylinders, the bottoms of which were closed with wire gauze, were filled in different cases with clay (80 per cent) and humus (20 per cent), clay (80 and 90 per cent) and lime (10 and 20 per cent), and sand (90, 94, 98, 99, and 99.5 per cent) and lime (0.5, 1, 2, 6, and 10 per cent). These cylinders were placed in water just deep enough to come in contact with the bottom of the soil, and the time required for the water to reach the surface of the soil, the water content of the soil thus moistened by capillarity, and the condition of the soil after drying were noted. The conclusions reached were that lime increases the water capacity of all soils and that it makes clay more pervious and friable and sand closer and more adhesive.

Experiments in capillarity with long tubes, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 4, 5, fig. 1*).—A brief record is given of observations on the rise of water in long tubes filled with loam from different depths (0 to 6, 6 to 12, and 12 to 18 in.) in the soil, and with pure sand, sandy soil, and clay loam. The rapidity of rise of water increased but the percentage of water absorbed decreased with the depth at which samples of loam were taken. The capillary rise was most rapid in the pure sand, but ceased when a height of 26.6 in. above the level of the standing water was reached, this limit being attained in 5 days. The rate of capillary rise in all cases decreased with the height above the level of free water. The fine clay soil absorbed about 35 per cent more water than either of the other samples.

Analyses of waters (*California Sta. Rpt., 1895-1897, pp. 76-102*).—Analyses showing mineral constituents in 16 samples of lake and stream waters, 32 samples of spring waters, and 44 samples of well waters are reported.

Engineer's report on waterworks, A. MARSTON (*Iowa State College Agr. and Mech. Arts Rpt. 1896-97*, pp. 39-48, pls. 4).—An account of the water plant recently constructed at the college.

Soils of San Joaquin Valley Substation, California, C. H. SHINN (*California Sta. Rpt. 1895-1897*, pp. 348-350).—The character of the strata passed through in boring a 60-foot well is noted. The different soil belts of the region east of Tulare Lake to the Sierra foothills are described and analyses of 3 samples of typical soils are reported. Analyses of an alkali crust and of water from a bored well are also given.

Rocks, clays, coals, plants, and miscellaneous substances (*California Sta. Rpt. 1895-1897*, pp. 103-106).—Analyses of asphalt, sepiolite (meerschauum), shell rock, and concentrated lye, and tests of the behavior of asphaltum bricks at different temperatures are reported, with a list of a large number of rocks, minerals, plants, etc., sent to the station for identification.

Catalogue of the collection of Russian soils, V. V. DOKOUCHAYEV (*St. Petersburg, pp. 166; abs. in Selsk. Khoz. i Lyesov., 184 (1897), Mar., p. 714*).—Classified according to different Governments and districts.

The analytical results of the specimens of soils exhibited by the Geological Survey of Japan at the Seventh International Geological Congress, at St. Petersburg, Russia (*Imp. Geol. Survey Japan. Tokio, 1897, pp. 28*).

The most recent works on soils (*Selsk. Khoz. i Lyesov., 187 (1897), Oct., pp. 187-216*).

Variations of soil moisture through May, June, and July, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 5-7, chart 1*).—The results of a series of moisture determinations in a plat of soil during these months, together with the rainfall and average temperature, are shown in a chart.

Soil temperatures (*New York State Sta. Rpt. 1896, pp. 712-717*).—A tabulated summary of tridaily observations during 1896 at depths of from 1 to 18 in.

Analyses of soils, A. K. SABANINE (*Contrib. Agr. Lab. Univ. Moscow, 1896, pp. 47; abs. in Selsk. Khoz. i Lyesov., 185 (1897), Apr., p. 242*).—Analyses of chernozem soils from different localities of Russia indicate that these soils increase in water content, humus, nitrogen, clay, and silt as one proceeds from West to East.—P. FIREMAN.

Examination of soils (*California Sta. Rpt. 1895-1897, pp. 29-37*).—Analyses showing coarse material, fine earth, hygroscopic moisture absorbed at 15° C., moisture and organic matter, humus, nitrogen, and mineral constituents in 2 samples of soil from the Foothill region, 5 from the Great Valley region, and 7 from southern California are reported. A list of soils received for examination is also given.

Examination of soil from Lake Temiscaming, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 7-9*).—The results of mechanical and chemical analyses of a sample of soil from this region are reported and its water capacity, texture, and fertilizer requirements discussed.

Survey of the literature on the culture of moors (*Selsk. Khoz. i Lyesov., 187 (1897), Nov., pp. 413-434*).

FERTILIZERS.

Commercial fertilizers (*Connecticut State Sta. Rpt. 1897, pp. 65-157*).—This includes abstracts of the State laws relating to fertilizers, a list of the manufacturers complying with the provisions of the fertilizer law, a brief summary of the work of fertilizer control in sampling, collecting, and analyzing fertilizers during the year, explanations concerning the analysis and valuation of fertilizers, fertilizer sales in Connecticut, a review of the fertilizer market for the year ending October 31, 1897, by E. H. Jenkins, and tabulated analyses and valuations of

548 samples of fertilizing materials, classified as follows: (1) Raw materials containing nitrogen as the principal ingredient—nitrate of soda, sulphate of ammonia, dried blood, cotton-seed meal, linseed meal, castor pomace, horn, and hoof; (2) raw materials containing phosphoric acid as the principal ingredient—dissolved boneblack and acid phosphate; (3) raw materials containing potash as the principal ingredient—high-grade sulphate of potash, double sulphate of potassium and magnesium, muriate of potash, kainit, and soap boilers' "potash"; (4) raw materials containing nitrogen and phosphoric acid—bone manures, tankage, and dried fish; (5) mixed fertilizers—bone and potash, nitrogenous superphosphates, guanos, special manures, bone and wood ash fertilizer, and home mixtures; (6) miscellaneous fertilizers and manures—cotton-hull ashes, wood ashes, limekiln ashes, lime, tobacco stems, garbage fertilizer, and earth impregnated with sewage.

In the 13 samples of nitrate of soda examined, the percentage of nitrogen varied from 15.02 to 16.27, the cost per pound of nitrogen from 13.7 to 15.6 cts. with an average of 14.6 cts. The cost per pound of nitrogen in 2 samples of sulphate of ammonia was 14.4 cts. "Sulphate of ammonia, which of late years has been too costly to warrant its use as a fertilizer, is not now more expensive than nitrate of soda as a source of nitrogen."

In 65 samples of decorticated cotton-seed meal examined during the year the percentage of nitrogen varied from 6.92 to 8.02, averaging 7.4. The average cost per pound of nitrogen in these samples was 11.6 cts. In one sample of undecorticated cotton-seed meal examined the percentage of nitrogen was 4.48 and its cost per pound 16.4 cts. "Decorticated cotton-seed meal continues to be the cheapest source of quickly available organic nitrogen. Its use is becoming more general in the tobacco growing sections of this State, but it deserves the attention of farmers generally."

The percentages of nitrogen in 2 samples of castor pomace were 4.51 and 4.02, and the cost per pound of nitrogen 18.5 and 21.1 cts., thus showing this fertilizer to be "the most expensive form of organic nitrogen in our market."

Analyses of 7 samples of dissolved boneblack showed a variation in cost per pound of available phosphoric acid of from 5.9 to 6.8 cts., and in 6 samples of dissolved rock phosphate of from 4.4 to 8 cts. "Available phosphoric acid almost invariably costs more in the form of dissolved boneblack than in the form of dissolved rock phosphate," the average price per pound in the former case being about 6½ cts., in the latter 5 cts.

The average cost per ton of the bone manures examined during the year was \$29.61; the average station valuation, \$28.03, "showing that the station schedule of values for bone has been scarcely lower than is justified by the average selling price of bone."

"The retail cash cost of potash in cents per pound in the various potash salts whose analyses are given . . . [was] as follows:

Retail cash cost per pound of potash in different forms.

	Highest.	Lowest.	Average.
	<i>Cents.</i>	<i>Cents.</i>	<i>Cents.</i>
In high-grade sulphate.....	5.5	4.7	5.4
In double sulphate.....	6.0	4.7	5.7
In muriate.....	4.5	3.9	4.2
In kainit.....	5.4	4.8	5.1

"Of the 101 analyses of nitrogenous superphosphates [reported], 20 are below the manufacturers' minimum guarantee in respect of one ingredient and 2 in respect of two ingredients. The number which failed to come up to the guarantee is considerably smaller than in the previous year. The average cost of the nitrogenous superphosphates is \$30.41. The average valuation is \$20.71, and the percentage difference 46.9."

Of the 100 samples of special manures examined 25 failed to conform to the manufacturers' guarantee as regards one ingredient and 4 were deficient in two ingredients. The discrepancies were specially marked in cases of mixtures of ground bone and chemicals.

"These inequalities are due to the nature of the materials used. It is extremely difficult to uniformly mix dry bone—or some kinds of blood tankage—with fertilizer chemicals, and when once mixed the slight jarring incident to storage and transportation is sufficient to cause considerable mechanical separation of the particles of bone or tankage from the chemicals. Even when a small sample has been very finely pulverized for analysis great care is necessary to avoid this separation of the different ingredients."

The average cost per ton of the special manures examined was \$34.34, the station valuation \$24.28, and the percentage difference 41.4.

Of 10 samples of home-mixed fertilizers examined, the average cost per ton was \$29.16 (including \$2 per ton for mixing), and their average valuation on the basis of the station's schedule was \$29.07.

[In 55 samples of cotton-hull ashes] the highest percentage of potash was 36.45, the lowest 10.26, while the average percentage was 22.4, slightly lower than the average in the previous year (23.1). Allowing 5½, 5, and 2 cts. per pound, respectively, for water-soluble, citrate-soluble, and insoluble phosphoric acid, the water-soluble potash has cost from 5.1 to 17.6 cts. per pound, or 7.9 per pound on the average.

The percentage of potash [in 20 samples of wood ashes] ranged from 3.44 to 8.60, and that of phosphoric acid from 0.97 to 2.69. Lime has ranged from 27.29 to 50.96, and sand and soil from 5.85 to 20.39. . . . As respects the cost of lime in these ashes, we find that on the average a ton of unleached wood ashes this year has contained 108 lbs. of water-soluble potash, 24 lbs. of phosphoric acid, and 650 of lime. Allowing 5 cts. per pound each for potash and phosphoric acid, the pure lime (calcium oxid) in the 20 samples would cost 57 cts. per 100 lbs., or 10 cts. more per hundred than in limekiln ashes.

The number of fertilizer firms doing business in Connecticut in 1897 was 56; the number of brands offered for sale, 281. There has been no great increase in the number of firms during 15 years (1883-1897), but a decided increase in the number of brands, mainly of special manures.

Composition of the ashes of different woods, R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 27-31*).—In continuation of previous work (E. S. R., 9, p. 435), the following analyses of ashes of different woods were made:

Composition of the ash of different kinds of wood and of coal and garbage.

	Potassium oxid.	Sodium oxid.	Phosphoric acid.	Calcium oxid.	Magnesium oxid.	Oxid of iron.	Sulphuric acid.

“The fact that these ashes were pure and prepared from the wood only, explains why the percentages of mineral constituents are so much higher in those found in the average ashes in the market.”

Some of the ashes were digested in 1 per cent citric acid¹ with the following results:

Percentages of available potash, phosphoric acid, and lime in different kinds of ashes.

Kind of ashes.	Potassium oxid.	Phosphoric acid.	Calcium oxid.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>

“Nearly 80 per cent of the total potash of the birch ash was found in the solution and practically the whole of that of the walnut ash. An average of the 9 samples experimented with shows that 87.5 per cent of the total potash of the different ashes was soluble in the citric-acid solution. According to this method of determining availability of plant food, all but 12.5 per cent of the potash would be in a form in which growing plants could make use of it at once. Smaller amounts of the phosphoric acid and lime appeared to be soluble. In some cases the amount of phosphoric acid was so small that it was not determined, but simply entered as traces.”

Experiments on the availability of fertilizer nitrogen, S. W. JOHNSON, E. H. JENKINS, and W. E. BRITTON (*Connecticut State Sta. Rpt. 1897, pp. 257-277*).—This is a continuation of work of previous

¹See also Canada Expt. Farms Rpt. 1896, p. 201 (E. S. R., 9, p. 825).

years (E. S. R., 9, p. 540). The apparatus and methods employed were essentially the same as in the earlier experiments, except that the soil used was taken from the field which has been devoted to experiments on the continuous growth of maize on the same land (E. S. R., 9, p. 551). Three series of experiments were undertaken: (1) With oats followed by Hungarian grass; (2) with Hungarian grass; and (3) with rye and oats followed by Hungarian grass. The soil used was a sandy loam on which maize had been grown continuously for 8 years and which had received no fertilizing material of any kind for 6 years. With the exception of nitrate of soda and ground bone, the fertilizing materials used were the same as in the experiments of 1896. At the beginning of the experiment the moisture content of the soil in the pots was kept between 10 and 15 per cent. When the heads first began to appear the quantity of water was increased so that the moisture content of the soil was between 15 and 20 per cent. After the removal of the oat crop (both roots and above-ground part) from the pots, the soil was returned to the pots without further addition of the fertilizers and Hungarian grass was planted. Details as to fertilizers applied and the weight and nitrogen content of the crops produced are given in full in a table. The principal results are summarized as follows:

Percentage availability of different forms of nitrogen in pot experiments with oats and Hungarian grass.

	Experiments in 1897.				Average of experiments, 1894-1896.	Nitrogen availability reckoned on nitrate, 1897.
	1.6 gm. fertilizer.	1.2 gm. fertilizer.	0.8 gm. fertilizer.	Average.		
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Nitrate of soda	(79.6)	(89.3)	102.5	102.5	64	100.0
Dried blood	(65.1)	73.1	77.3	75.2	43	73.3
Dry ground fish	(60.3)	57.3	63.6	65.5	44	63.9
Ground bone		18.3	16.1	17.2		16.7
Tankage	49.8	48.8	53.4	50.7	38	49.4
Horn and hoof	(68.8)	67.9	72.1	70.0	42	68.3
Linseed meal	(60.4)	68.7	72.4	70.6	45	68.9
Cotton-seed meal	(59.2)	65.1	67.7	66.4	46	64.8
Castor pomace	(59.9)	66.4	66.0	66.2	47	64.6

"It appears that in every case a much larger percentage of the fertilizer nitrogen was taken by the crops in the experiments of 1897, natural soil, than in the previous cultures made in coal ashes and peat. Part of this increase is due to the inclusion of roots with the crops in 1897.

"The percentage availability of nitrogen to the oat crop of 1897 would have been made less by about 12 per cent on the average if the roots had been excluded.

"If we may assume that a like percentage added to the percentage availability as determined in the experiments of 1894, 1895, and 1896 will correctly compensate for the exclusion of the roots in those experiments, it still appears that on the average a larger percentage of nitrogen was assimilated in the experiments of 1897 than in the earlier ones. This is particularly noticeable in the case of nitrate and of dried blood.

"In these experiments of 1897 the nitrogen of raw knuckle bone, ground to pass a sieve with circular holes one-fiftieth of an inch in diameter, had only one-sixth of the availability of the nitrogen of nitrate, one-quarter of that of linseed, cotton seed,

castor pomace, steamed horn and hoof, and fish, and about one-third of that of tankage. The bone used was very dense and hard, unlike most of the ground bone which is sold in our market as a fertilizer, and presumably less readily available. The subject is further discussed in the following paper. . . .

"The nitrogen of tankage (which contains considerable bone, 'bone tankage') has an availability, compared with that of nitrate-nitrogen, of 49 per cent, while the nitrogen of cotton seed, linseed, and castor pomace, as well as that of horn and hoof and in fish, had an availability of from 61 to 69 per cent.

"The experiments of 1897 shew but little difference in the availability of nitrogen in cotton seed, linseed, castor pomace, horn and hoof, and fish. In this year the nitrogen of blood had a higher availability than that of the materials just named."

In the second series of experiments (with Hungarian grass) "the apparatus and method, kind and amount of soil, method of mixing and filling, watering and care during growth" were the same as in the above experiments. With the soil of each pot were carefully mixed 50 gm. of carefully precipitated calcium carbonate and 5 gm. of potassium phosphate containing 0.1971 gm. of phosphoric acid and 0.2629 gm. of potash. The nitrogenous materials used were nitrate of soda, cotton-seed meal, and bone in three different grades of fineness ($\frac{1}{150}$ in., $\frac{1}{50}$ in., and $\frac{1}{25}$ in.). Detailed data are given in a table. The principal results may be summarized as follows:

Percentage availability of different forms of nitrogen in pot experiments with Hungarian grass.

	Experiments in 1897.				Nitrogen availability reckoned on nitrate.
	1.6 gm. ferti-zer.	1.2 gm. ferti-zer.	0.8 gm. ferti-zer.	Average.	
Nitrate of soda.....	<i>Per cent.</i> 74.6	<i>Per cent.</i> 95.3	<i>Per cent.</i> 95.2	<i>Per cent.</i> 95.3	<i>Per cent.</i> 100.0
Cotton-seed meal.....	58.1	53.3	54.3	55.2	57.9
Bone, grade A.....	10.5	12.0	9.9	10.8	11.3
Bone, grade B.....	7.0	6.9	10.4	8.1	8.5
Bone, grade C.....	3.9	6.2	5.9	5.3	5.6

a Excluded from the average.

"It thus appears that in these cultures, while 95.3 per cent of the nitrogen of nitrate of soda and 57.9 per cent of that of cotton-seed meal were taken up by the crop, under similar conditions, only 11.3 per cent of the nitrogen of the finest bone flour was taken by the crops and still less than that percentage from coarser grades.

"These figures do not indicate that the nitrogen of bone is always or generally inferior to that of other animal and vegetable materials.

"Bone finds its most profitable use on crops like grass and clover, which are not annuals, but whose roots occupy the soil through the whole year and are more or less active at all seasons.

"The best grass lands, too, are loams inclined to be heavy or clayey rather than sandy and, in consequence, retentive of moisture. On such soils it is very likely that bone decomposes more rapidly than in the sandy loam of our experiment and the perennial roots of the crops named would certainly be more efficient in taking up the nitrogen of fertilizers than those of the short-lived plants (oats and Hungarian grass) used in our experiments. It should also be noted that the bone used by us was of the hardest kind, such as is used for the manufacture of 'ivory' goods, which is presumably more slowly decomposed and dissolved in the soil than other sorts."

In case of the third series of experiments (rye and oats followed by Hungarian grass), the crops were greatly damaged by excessive rains and the results are withheld from publication.

Improvement and fertilization of land, E. W. HILGARD (*California Sta. Rpt.* 1895-1897, pp. 107-111).—A brief discussion of the fertilizer requirements of plants and the use of fertilizers, especially on California soils; suggestions regarding fertilizer experiments; and analyses of 15 samples of fertilizing materials, including gypsum, dust from sheep fleeces, phosphate, soil from Indian burial ground, guano, clay, shell rock, lime refuse, and waste water from sugar-beet factories.

Report of analyses of commercial fertilizers for the fall of 1896, L. L. VAN SLYKE ET AL. (*New York State Sta. Rpt.* 1896, pp. 204-261).—Reprint of Bulletin 116 of the station (E. S. R., 9, p. 122).

The real value of natural plant food, L. L. VAN SLYKE (*New York State Sta. Rpt.* 1896, pp. 119-124).—A reprint of Bulletin 108 of the station (E. S. R., 8, p. 766).

Alkali, C. H. SHINN (*California Sta. Rpt.* 1895-1897, pp. 350-352).—The rise of alkali in the experimental fields of the San Joaquin Valley Substation is discussed and experiments with gypsum for correcting alkali are reported. When this substation was first established alkali did not show, except in three or four spots on the experimental field, but as cultivation has proceeded the rise and spread of the alkali has been very rapid. Gypsum, in connection with irrigation and underdraining, has given good results in correcting the alkali.

FIELD CROPS.

Report of the agricultural department, W. C. LATTA (*Indiana Sta. Rpt. 1897, pp. 51-59*).—In this report the work of the year is outlined and the results of the experiments briefly summarized. The work is largely a continuation of former experiments (*E. S. R., 9, p. 347*). Among 13 varieties of wheat, Russian, Michigan Amber, Velvet Chaff, and Bearded Winter Fife, and among 21 varieties of oats, White Russian, White Swede, and Black Prolific, were the most promising varieties.

A test of fertilizers on oats was made on two series of plats, one of which had produced crops in a regular rotation, while the other had grown grain crops for the same length of time. There were 10 plats in each series, including 3 check plats which had received no fertilizer. Acidulated phosphates, nitrate of soda, and muriate of potash were applied in different quantities. On the plats which had been in the rotation the best yield (68.12 bu. per acre) was produced by the application of 125 lbs. acidulated phosphate, 37½ lbs. nitrate of soda, and 15 lbs. muriate of potash per acre, but the yields of the check plats were 48.19 bu. per acre for the first, 53.28 bu. for the second, and 68.28 bu. for the third. On the series of plats which had produced grain continuously, the best yield was 68.91 bu. per acre, which was obtained from the plat fertilized with 145 lbs. acid phosphate, 75 lbs. nitrate of soda, and 15 lbs. muriate of potash per acre. The yield from the check plats in this series varied from 50.78 to 53.90 bu. per acre.

Cultivating corn 1 and 3 in. deep gave better yields than cultivating 2 and 4 in. deep. The average results for 9 years have been in favor of cultivating 1 in. deep.

From the results of the experiments it is concluded unwise to attempt the growing of winter oats in that latitude. Notes are given on grasses, clovers, and forage crops, and experiments on previous manuring on the yield of corn, heavy and light applications of manure and fertilizer, and continuous growing of clover, as yet incomplete, are described.

Chicory growing as an addition to the resources of the American farmer, M. G. KAINS (*U. S. Dept. Agr., Division of Botany Bul. 19, pp. 52, figs. 12*).—This bulletin describes the chicory plant and its uses and gives directions for growing the crop for the root and for fodder. Details of the preparation of the soil, sowing, cultivation, and storing the crop, statistics on the importation of chicory since 1869, and analyses of the raw and roasted root are given. Three varieties, Brunswick, Magdeburg, and Schlesiische, considered the best known kinds used in America for roasting, are described.

The results of experiments in the germination of seeds from early and late chicory flowers and of large and small seeds are reported in tables. "The ratio of good to poor seed in individual flower heads proved, in all cases examined, to be in favor of the early flowers."

Weight and germination of large and small seeds.

Large seed.								Small seed.							
Weight of 100 seeds sown.	Days.							Weight of 100 seeds sown.	Days.						
	2	3	5	9	15	21	2		3	5	9	15	21		
<i>Mg.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>Mg.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>
226.14	13	28	59	75	86	91		81.20	6	11	25	39	46	51	
208.16	9	22	49	68	79	85		81.20	4	9	17	24	30	33	
207.02	11	23	50	71	83	88		80.00	3	8	18	26	31	33	
190.09	8	19	40	63	74	81		79.84	4	7	14	20	23	26	
114.00	5	13	29	49	58	63		81.05	2	5	10	15	17	19	

“Not only was the percentage of germination in favor of the large seeds . . . but the time required to get a fairly good stand was also much less.”

Experiments with field roots, silage, and forage crops. C. A. ZAVITZ (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 186-213*).—This work consisted of variety tests, distance experiments, and selection of seed with a number of different crops. All results are tabulated. Work in this line has been formerly reported (*E. S. R., 9, pp. 440, 443*).

Swedish turnips.—In a test of 79 varieties planted 10 in. apart in rows 26 $\frac{2}{3}$ in. apart, Improved Long Island and Dreer Improved Purple Top produced the heaviest roots. Improved Long Island, Laidlaw Improved, and Dreer Improved Purple Top produced the largest yields of roots (29.25, 28.25, and 27.85 tons per acre, respectively.) Of 29 varieties tested for 9 years Hartley Bronze Top heads the list in productiveness with an average yield of 21.11 tons of roots per acre. From the results of experiments conducted for 6 years in succession the general conclusion is drawn that as the distance between plants in the row increased from 8 to 20 in., the average yield decreased, but the average weight per root increased. The average yield of plants 4 and 8 in. apart was 17.26 and 17.58 tons of root per acre, respectively. The average results for 6 years showed that drills 20 in. apart gave a better yield than drills 26 and 32 in. apart.

Fall turnips.—On the average of 7 years' experiments Jersey Navet, Graystone Improved Purple Top Mammoth, and Early American Purple Top, in the order given, produced the heaviest roots. Thinning the plants to 4 in. apart in rows 26 $\frac{2}{3}$ in. apart gave a better average result for 6 years than thinning to 8, 12, 16, or 20 in. apart. A test of different distances between drills with plants 10 in. apart in the drill proved 20 in. to be preferable to 26 or 32 in.

Mangel-wurzels.—This season 62 varieties were tested. Among 27 varieties grown for 7 years Evans Improved Mammoth Sawlog produced the largest average yield, 25.17 tons per acre, followed by Simmer Improved Mammoth Long Red with 25.11 tons and Steel Long Red Selected with 24.24 tons per acre. Four inches between roots in drills 26 $\frac{2}{3}$ in. apart and 20 in. between drills with 10 in. between plants in the drill proved to be the preferable distances. The average weight of the

roots thinned to 20 in. apart was over 5 lbs., while that of those 4 in. apart was only a little over 1 lb.

Sugar beets.—Lane Improved, White Silesian, Red Top, Champion, White French, and Kleinwanzlebener, named in the order of their productiveness, yielded on the average for 6 years over 15 tons per acre. The average yield for Lane Improved was 19.07 tons per acre.

In experiments with mangels, carrots, sugar beets, Swedish turnips, and fall turnips it was found that planting the seed 1 in. deep gave better results than planting 2, 3, or 4 in. deep, and that large, plump seed gave better yields than medium or small seed. Thinning mangels, carrots, and Swedish and fall turnips, when the plants were from 1½ to 2 in. high, gave better results than thinning when the plants were from 8 to 10 in. high. Slightly better yields were obtained with flat cultivation than with ridged cultivation. Tests were made of 18 varieties of millet, 3 of sunflower, 20 of grass, and a number of varieties of rape, kale, clover, and other miscellaneous crops.

Experiments with varieties of grain, C. A. ZAVITZ (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 154-186*).—These experiments are along the lines of work reported in previous years (E. S. R., 9, p. 440). All varieties of different crops obtainable in Canada and the leading varieties from the United States and various countries in Europe, Asia, Africa, and Australia were tested, and some excellent foreign varieties have been obtained. Other features, such as method and time of sowing, selection of seed, time of harvesting, etc., were studied in connection with this work. The results for 1897 and the average results for the number of years the varieties were grown are given in tables. All plats were $\frac{1}{100}$ acre in size.

Barley.—Fifteen six-rowed, 19 two-rowed, and 12 hulless varieties were on trial. The seed was sown broadcast April 28 at the rate of 100 lbs. per acre. Oderbrucker, Scotch Improved, Jarman Selected Beardless, and Manitoba six-rowed produced the heaviest grain, the weight per measured bushel varying from 51.1 to 51.9 lbs. Oderbrucker weighed about 53.25 lbs. on an average for 9 years. Taking the average results, Mandscheuri and Oderbrucker were the most productive varieties tested. The average yield of Mandscheuri for 9 years was 63.6 bu. per acre, while the yield of Oderbrucker was 55.92 bu. The average weight per measured bushel of Mandscheuri for the same period is about 2½ lbs. less than that of Oderbrucker. The average yield for this season was 38.3 bu. for the six-rowed varieties and 38.8 for the two-rowed varieties. Among the hulless varieties in the average for the number of years they were grown Black Hulless, Three-rowed, Guyamala, and Purple have yielded grain weighing over 60 lbs. per measured bushel, this weight being taken as the standard. Black Hulless yielded the best average for 8 years, 38.17 bu. per acre. An experiment in broadcasting and drilling on different dates resulted in the largest yield from barley drilled April 19.

Peas.—Forty-seven varieties of peas were sown in drills 1 link apart. The yields varied from 14.55 bu. to 33.1 bu. per acre. Chancellor matured first and Oakshott Field last, there being a difference of 24 days in the ripening period of the 2 varieties. The best average yields for 7 years ranged from 33.36 to 38.04 bu. per acre and were produced by White Wonder, Early Briton, Field, Mummy, Brown, and Blue, in the order given. All excepting Early Briton and Mummy are New Zealand varieties. In general, during a two-years' test, drilling gave better results than broadcasting. Sowing on different dates resulted in the highest average yield from the seeding made April 22 as compared with earlier and later dates.

Spring wheat.—Tests were made of 48 varieties. Bart Tremenia, Wild Goose, Medeah, Sorentina, and Algiers were the most productive of the coarse-grained wheats and Herison Bearded, Saxonka, Konisburg, Red Fern, Red Fife, Colorado, Rio Grande, Washington, Wellman Fife, and Blue Democrat among the fine-grained varieties. Herison Bearded in 9 years' trials has given an average yield of 26.5 bu. per acre, at an average weight of 62½ lbs. per measured bushel. In general, broadcasting gave better results than drilling. The first seeding of wheat, made April 19, gave a better yield than the later ones. As the time of seeding advanced the crop decreased in quantity and quality.

Winter wheat.—A test of 91 varieties was made on 189 plats. Early Red Clawson, Golden Drop, Early Genesee Giant, Imperial Amber, Dawson Golden Chaff, Tuscan Island, and Egyptian, in the order given, produced the largest yield. These varieties also stand first in productiveness among 86 varieties grown for 4 years in succession. Dawson Golden Chaff has given a yield of 50.5 bu. per acre in the average of 6 years' tests.

For 5 years winter wheat has been sown on September 3, 9, and 20. This season's sowing (September 9) gave the best results, but the average for the whole period is in favor of the earlier date. The results from drilling and broadcasting the seed were very similar in this year's test, as well as in the average for 4 years. Sowing seed at the rate of 2 bu. per acre gave better results than sowing at the rate of 1½ and 1 bu. per acre. An experiment in the selection of seed resulted in the best yield from the large plump seed as compared with small plump, shrunken, or cracked seed. The use of sprouted grain for seed showed that sprouting impairs the germinating power and tends to produce an uneven crop.

On 12 plats, each 1 rod wide by 6 rods long, the soil was given different treatment previous to sowing. The experiment was duplicated, there being 6 plats in each set. These plats were plowed in the fall of 1895 and received surface cultivation the following spring. Four plats of each set were sown to oats, buckwheat, rape, and clover, and the other two were worked as bare summer fallow. The green crops were plowed under about August 1 and barnyard manure at the rate of 20

tons per acre was applied to one of the bare fallow plats in each set. The wheat was sown August 25. The bare fallow plats which had received the barnyard manure produced the heaviest yield, but the method of treatment was also the most expensive. Green manuring with peas was more effective than green manuring with rape or buckwheat or bare summer fallow without barnyard manure.

A study was made of the effect of cutting at different stages of maturity, the average dates of cutting for 4 years being July 4, 11, 18, 25, and August 1. In each year the greatest yield of straw was obtained from the first cutting, the heaviest grain per measured bushel from either the second or third cutting. The lowest yields and the lightest grain were obtained from the first cutting of each variety in each year. The best average yield for 4 years was obtained from the cutting made July 25.

Oats.—Comparative tests of 103 varieties were made. In general the varieties with a spreading head gave most satisfactory results. Joannette, a black variety, has given the largest average yield of grain among all the varieties tested, 86.08 bu. per acre. But few of the black varieties rank high in productiveness. Siberian, Oderbrucker, Waterloo, Probsteier, and Danebrog, all of which are white varieties, gave an average yield of over 75 bu. per acre in a 9-year test. The results in favor of the drilled grain as compared with grain sown broadcast were more marked than in the case of some of the other crops. Oats sown April 22 gave a larger yield this season than seed sown earlier or later, and this was true for the average of 3 years.

Beans.—Among 31 varieties White Wonder, Burlingame Medium, Medium, Schofield, and Snowflake, in the order named, were most productive, their yields ranging from 31.47 to 36.77 bu. per acre.

Mixed grain.—Eleven different combinations of barley, peas, oats, and wheat were tested for the production of grain and straw. Barley, peas, and wheat gave the best yield of grain and barley and peas the largest yield of straw for this season, but the best average yield in straw and grain for 5 years was produced by a mixture of barley and oats.

Seed selection.—Different qualities of seed of barley, spring wheat, white oats, and peas were selected and tested. In a 3-year trial with barley, wheat, and oats, in every case except two large plump seed produced the largest kernel as compared with small plump and shrunken seed.

Dark-colored plump, light colored and light weight, and hulled grain of Joannette oats were selected and compared. The light seed produced the smallest grain, the hulled seed the next smallest, and the large plump the largest and heaviest grain. Sound peas for seed gave better results than cracked peas, and large peas better yields than small ones.

Tests of 3 varieties each of spring rye and buckwheat are reported.

Sugar beets in Colorado in 1897, W. W. COOKE and W. P. HEADDEN (*Colorado Sta. Bul.* 42, pp. 1-38).—This bulletin gives the report

of cooperative culture experiments with sugar beets in 1897. Chemical analyses of soils from five different sections of the State and instructions for the growing of sugar beets are given. The results are tabulated in detail and sugar-beet culture is discussed in general. From the results obtained it is concluded that good sugar beets can be raised in any part of Colorado which is adapted to any kind of farming, and that large crops of good beets can be grown in districts supplied with water for irrigation. The length of the campaign for the State is estimated at 120 days. The ripe crop of beets in 1897 averaged 15.5 per cent of sugar and 81.6 per cent purity. The average yield per acre was about 16 tons.

Influence of drying on beets (pp. 29-31).—On October 29 beets were taken from the field and divided into 3 equal lots: Lot 1 was kept for a day in a cool, dark place; lot 2 was left for a day in the open field; and lot 3 was piled up and covered with a few inches of dirt and left in the field for 5 weeks. The analyses gave the following results:

Influence of drying on beets.

	Treatment.	Sugar content.	Purity.
		<i>Per cent.</i>	<i>Per cent.</i>
Lot 1	Kept for a day in a cool place	14.0	82
Lot 2	Kept for a day in the open field	14.9	79
Lot 3	Kept for 5 weeks in the field	14.7	84

Lots 2 and 3 lost weight by drying out, but no fermentation of the sugar in the beet took place. It was found that green beets when left to dry sustain a loss of sugar by fermentation.

Influence of freezing on beets (p. 31).—Two beets, one slightly, the other decidedly frozen, were divided into three parts by weight and each third analyzed to ascertain the effect of freezing. Of the beet described as decidedly frozen, the upper third was all frozen, the middle third partly frozen, while the lower portion was left uninjured. The following table gives the results:

Effect of freezing on sugar beets.

	Sample partly frozen.		Sample decidedly frozen.	
	Sugar.	Purity.	Sugar.	Purity.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Upper third	12.9	78.7	10.9	73.2
Middle third	12.0	91.1	11.2	70.3
Bottom third	12.0	81.4	14.3	88.3

Sugar-beet growing in Iowa, 1897, C. F. CURTISS and J. ATKINSON (*Iowa Sta. Bul. 37, pp. 20, fig. 1*).—This is a popular bulletin on sugar-beet culture, giving the results of culture experiments at the station and throughout the State. Results are given in a table.

The average sugar content of 663 samples obtained from the cooperative tests was 13.07 per cent, with an average coefficient of purity of 77.4. The samples harvested earliest were poor in quality, while those harvested later made a better showing as the season advanced. This was also found to be the case in the experiments at the station. Six varieties were tested at the station, each variety being grown on six different plats under varying conditions. The results are given in the following table:

Average results of variety tests of sugar beets.

Name.	Sugar.	Purity.
	<i>Per cent.</i>	<i>Per cent.</i>
Schreiber	15.09	83.23

Drauz Elite.....	14.30	81.60
Zieman.....	13.30	79.72
Dippe.....	13.83	78.81
Vilmorin.....	13.32	80.11

Experiments in the fertilizing and curing of tobacco, 1897, E. H. JENKINS (*Connecticut State Sta. Rpt. 1897, pp. 223-230*).—A series of fertilizer experiments were begun to compare the effect of barnyard manure and commercial fertilizers—a mixture of barnyard manure and commercial fertilizers, and green manuring with a leguminous crops—on the quality of the leaf. The crop was harvested and was undergoing curing by artificial heat when it was destroyed by fire.

A note is given on the process of pole-curing, and the work of curing the crop so far as completed is fully described. The temperature of the curing barn was never higher than 88° F. and seldom over 82°, and was kept as nearly uniform as possible throughout the building. The author cautions against chilling tobacco by low temperatures and allowing it to become dry before it has come to color and against curing it irregularly.

Experiments in growing tobacco with different fertilizers—report on the fermented crops of 1896, E. H. JENKINS (*Connecticut State Sta. Rpt. 1897, pp. 230-243*).—This report is the conclusion of experiments begun in 1892 and completed in 1896, some of the results obtained in these tests having been previously reported (*E. S. R., 9, p. 543*). The details of expert judgment on each lot of tobacco from the experimental plats in 1896 are given. The average results obtained by fermentation and the relative quality of the leaf from the different plats, taking the entire period into consideration, are reported below.

Results of the experiments with tobacco fertilizers for the years 1892 to 1896, E. H. JENKINS (*Connecticut State Sta. Rpt. 1897, pp. 243-256*).—The results of these experiments and the manner in which they were conducted are discussed in a previous report of the station (*E. S. R., 9, p. 543*) and are here briefly summarized, with the

additional facts brought out by the fermentation of the crop of 1896. The effect of fermentation on the weight and fire-holding capacity of tobacco is shown in the following table, which gives the averages of all the plats under experiment:

Average weight and fire-holding capacity of wrapper leaves.

	Average number of wrapper leaves per pound.		Average fire-holding capacity in seconds.	
	Before fermentation.	After fermentation.	Before fermentation.	After fermentation.
Short wrappers.....	87	92	12.0	28.5
Long wrappers.....	64	68	9.2	23.9

The long and short wrappers in the sorted crops averaged 60.7 per cent, some plats yielding as high as 78 per cent of wrappers. The average yield per acre of pole-cured, sorted tobacco for all the plats was 1,685 lbs., the maximum being 2,280 lbs. and the minimum 1,145 lbs. per acre. The average loss of weight in sorting ranged from 4.5 to 5.3 per cent. The following table shows the comparative value of the leaf from the several plats. The number expressing the relative quality is the average of the numbers representing the grading of the tobacco for each year, the smaller numbers representing the higher values:

Comparative value of the leaf from all the plats for five years.

The discussion of the results is practically the same as that given in the previous report (E. S. R., 9, p. 543).

Report of the farm superintendent, W. RENNIE (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, pp. 215-217).—Notes on the different crops grown in 1897.

Superphosphate as a fertilizer for barley, M. ULLMANN (*Deut. Landw. Presse*, 25 (1898), No. 14, p. 115).—The results of experiments show that water-soluble superphosphate as a fertilizer produced a better yield and a better quality of barley than citrate-soluble superphosphate.

Analyses of cañaigre or tanners' dock, G. E. COLBY (*California Sta. Rpt. 1895-1897*, pp. 186-190).—A table is given showing the results of 82 analyses of cañaigre root, comprising all the results obtained at the station up to July, 1897. This is work in continuation of that already reported (E. S. R., 8, p. 686). The average of 30 analyses of California-grown cañaigre roots one year old was 27.7 per cent of tannin in the air-dried substance.

Harvest of flax and hemp seed in Russia during 1897, W. R. HOLLOWAY (*U. S. Consular Rpts. 1898*, No. 213, pp. 259, 260).—The amount of flaxseed harvested was 727,920 tons, being 28.5 per cent less than the crop of 1896. The amount of hemp seed produced was 316,800 tons, which was nearly 25 per cent less than the crop produced the previous year.

Silage and silos, W. P. WHEELER (*New York State Sta. Rpt. 1896*, pp. 641-656, pls. 2).—A reprint of Bulletin 102 of the station (E. S. R., 8, p. 222).

Report of grasses and fodder plants, A. B. LECKENBY (*California Sta. Rpt. 1895-1897*, pp. 298-301).—Brief notes on culture tests in southern California of plants "that offer special promise of usefulness as wild feed or have a direct bearing as a farm crop." The following crops were tested: Australian saltbush (*Atriplex semibaccata*), modiola (*Modiola decumbens*), sapling clover (*Trifolium medium*), common white clover (*T. repens*), black medic (*Medicago lupulina*), hairy vetch (*Vicia villosa*), sheep purslane (*Portulaca oleracea*), awnless and Schrader brome grasses (*Bromus inermis* and *B. unioloides*), orchard grass (*Dactylis glomerata*), Italian rye grass (*Lolium multiflorum italicum*), tall oat grass (*Arrhenatherum elatius*), small fescue (*Festuca elatior pratensis*), Eleusine barcinonensis, prolific panic grass (*Panicum proliferum*), pearl millet (*Pennisetum typhoidum*), Abyssinian feather grass (*P. longistylum*), teosinte (*Euchlana lurarius*), Bermuda grass (*Capriola dactylon*), squirrel tail (*Hordium jubatum*), ragi (*Eleusine coracana*), redtop (*Agrostis vulgaris*), fiorin grass (*A. alba*), barnyard grass (*Panicum crus-galli*), knot grass (*Paspalum distichum*), sheep fescue (*Festuca ovina*), rough meadow grass (*Poa trivialis*), annual poa (*P. annua*), and meadow soft grass (*Holcus lanatus*).

Some economic plants, C. H. SHINN (*California Sta. Rpt. 1895-1897*, pp. 330, 340).—Notes on crops of cañaigre, licorice, pyrethrum, cereals, and forage plants. Among the collection of varieties of wheat, Royal Australian was the best milling variety. The leading wheats among the varieties tested are given. Of the grasses tested for 6 years, Hungarian brome grass kept green in summer better than any other. Red clover and white clover were found to grow well in the rainy season and during the spring, but to fail later on when left unirrigated. Bokhara clover remained green during the summer without irrigation for several successive years. "Espareet keeps green during the dry season. It is valuable for this district, and succeeds far better on the light and shallow soil than on the heavier." The species succeeding best on the heavy soils of the swale were *Agropyron japonicum*, *Bromis inermis*, *Digitaria sanguinalis*, *Holcus lanatus*, *Lolium perenne*, *Agrostis vulgaris*, *Euchlana lurarius*, *Phalaris media*, *P. canariensis*, *Lotus tetragonolobus*, and *Melilotus alba*.

Small culture plats, C. H. SHINN (*California Sta. Rpt. 1895-1897*, pp. 384-389).—Notes on small culture tests with saltbushes, cotton, grasses, sorghum, sunflowers, and legumes. The crops were grown on a 10-acre tract of alkali soil. Of the low-growing species of saltbush *Atriplex semibaccata* was found to be the best. Among the grasses *Bromus unioloides*, *Eleusine coracana*, and *Lolium perenne italicum* made a good growth, but the different species of Fescuas, Poas, and Panicums were failures. Sunflowers and Jerusalem artichokes grew well on the alkali soils, but legumes were not successful. The tract was divided into separate plats. The alkali content and notes on the crop of each plat are given.

Notes on small cultures, A. V. STUBENRAUCH (*California Sta. Rpt. 1895-1897*, pp. 340-343).—Notes on experiments with tobacco, sugar beets, Australian saltbush, kale, and sorghums. Thirty-five varieties of tobacco were tested, and from results it is concluded "that the plant will thrive and grow through the hot summers, and . . . that of the long list of desirable varieties under cultivation some will . . . produce tobacco of a marketable quality."

Among the varieties of kale Dwarf German Greens made the best growth. "Wind or heat did not seem to affect it at all, nor did it receive any water during the summer."

Three varieties of sorghum, Safed Juar, Dewala, and Baedra peela, planted May 5, produced no seed during the season.

Report on grasses and forage plants, E. J. WICKSON (*California Sta. Rpt. 1895-1897*, pp. 271-292, pl. 1, figs. 4).—The early introduction of grasses and forage plants into California is discussed and later introductions of grasses, legumes, and miscellaneous fodder plants are noted. Concise reports of cooperative culture tests and descriptions of the following crops are given: Many-flowered millet grass (*Oryzopsis miliacea*), Schrader brome grass (*Bromus unioloides*), Japanese wheat grass (*Agropyron japonicum*), Texas blue grass (*Poa wachnifera*), tall oat grass (*Arrhenatherum elatius*), Hungarian or awnless brome grass (*Bromus inermis*), snail clover (*Medicago turbinata*), square pod pea (*Lotus tetragonolobus*), flat pea (*Lathyrus sylvestris*), tagasaste (*Cytisus proliferus albus*), sachaline (*Polygonum sachalinense*), Nepaul barley, and Jersey kale.

Culture experiments with different varieties of saltbush on alkali soils are briefly described.

Notes on hay growing, C. H. SHINN (*California Sta. Rpt. 1895-1897*, pp. 324, 325).—Short notes on the results of growing barley for hay during two seasons. The barley was sown at different intervals from October to February in both years. The crops were cut for hay in May and June. The effects of fertilizer applications are reported.

Jamaica hay, B. S. C. HEAVEN (*Jour. Jamaica Agr. Soc., 2 (1898), No. 7, pp. 278-281*).—A discussion on the preparation of hay from guinea grass. The food value of this hay and timothy are compared.

A few observations on Paspalum dilatatum, H. M. WILLIAMS (*Agr. Gaz. New South Wales, 9 (1898), pt. 5, pp. 507-509*).—The grass is highly recommended for permanent pasture and is considered one of the best for general purposes. "It has proved itself a mainstay for . . . stock, growing vigorously when the fierce heat had withered up the other grasses."

The cultivated vetches, J. G. SMITH (*U. S. Dept. Agr., Division of Agrostology Circ. 6, pp. 8, figs. 6*).—A revised edition (E. S. R., 10, p. 43), in which notes on Dakota vetch (*Lotus americanus*) and bird vetch (*Vicia cracca*) have been added.

The application of commercial fertilizers to spring grains, EMMERLING (*Fühling's Landw. Ztg., 47 (1898), No. 8, pp. 310-312*).—A discussion with special reference to fertilizers furnishing phosphoric acid and their effect upon the soil and crop.

Phosphoric acid and the cereals, C. GUFFROY (*Jour. Agr. Prat., 2 (1898), No. 28, pp. 52-54, figs. 2*).—Phosphoric acid was applied to wheat and barley at the rate of 500 kg. per hectare. Disregarding the yield, the author concluded from the results that phosphoric acid as a fertilizer for cereals increases the diameter and length of the stem and in general the rigidity of the plant, improves the development of the head, and increases the specific gravity of the grain.

The sorting of grain and the modern utensils for the purpose, VON RÜMCKER (*Fühling's Landw. Ztg., 47 (1898), No. 8, pp. 307-310, figs. 2*).—The importance of the specific gravity, size, and form of seeds of cereals is pointed out and methods of sorting the grain described.

The cultivation of potatoes in European Russia (*Rpt. Min. Agr. and Govt. Estates, Div. Rural Econ. and Agr. Stat. St. Petersburg, 1897, pp. VI+162+152; abs. in Selsk. Khoz. i Lysov., 186 (1897), Sept., p. 712*).—The first part of this report contains general information about potatoes; the second part contains descriptions of the culture of potatoes in different Governments.—P. FIREMAN.

Economy in using fertilizers for raising potatoes (*New York State Sta. Rpt. 1896*, pp. 107-118).—A reprint of Bulletin 112 of the station (E. S. R., 9, p. 128).

Sisal culture in Mexico, M. GÉNIN (*Bul. [Min. Agr. France] 17 (1898)*, No. 1, pp. 215-228, figs. 3).

Sugar beets, M. E. JAFFA (*California Sta. Rpt. 1895-1897*, pp. 125-141).—A report is given of analyses of samples received during the seasons of 1895 and 1896 from cooperative culture experiments made by farmers and the experiment substations. Culture tests made by farmers are grouped by counties. The details of all tests are given in notes and tables.

Analyses of sugar beets, R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, pp. 25-27).—Results of cooperative experiments.

Growing sugar beets for factories, G. H. WEST (*Colorado Sta. Bul. 42*, pp. 39-64, fig. 1).—A number of beet-sugar factories are described and notes are given on labor, factory customs and requirements, machines used in beet culture, the cost of making sugar, and the value of sugar beets and beet pulp for feeding purposes.

Sugar beets, C. F. CURTISS (*Iowa Agr. Col. Rpt. 1896-97*, pp. 105-111).—A partial reprint of Bulletin 37 of the station (see p. 241).

Planting sugar beets, C. D. SMITH and R. C. KEDZIE (*Michigan Sta. Spec. Bul. 8*, pp. 4).—Popular directions for growing sugar beets.

Cooperative sugar-beet work (*Nebraska Sta. Rpt. 1897*, pp. 23-26).—A short report on the arrangement of the cooperative experiments conducted and the results obtained. The average sugar content of the juice of 106 samples of beets from 36 counties was 12.34 per cent, with a purity of 75 per cent. The highest percentage of sugar in juice was 16.8, with a purity of 78.5, and the lowest 4.67, with a purity of 45 per cent.

Sugar beets, C. T. JORDAN (*New Mexico Sta. Bul. 23*, pp. 55-67).—General directions for sugar-beet culture and instructions for taking samples for analysis are given.

Tobacco (*Jour. Jamaica Agr. Soc., 2 (1898)*, No. 7, p. 294).—Directions for two methods of preparing beds for sowing tobacco seed are given.

Tobacco growing in Pennsylvania in 1897, F. R. DIFFENDERFFER (*Pennsylvania Dept. Agr. Rpt. 1897*, pt. 1, pp. 649-665, pl. 1).—This article presents the history, progress, and present condition of tobacco farming in Pennsylvania. The culture of the crop and the importance of the industry are discussed in a popular way.

Wheat culture experiments (*Agr. Jour. Cape of Good Hope, 12 (1898)*, No. 9, pp. 471-474).—A report on variety tests of wheat. Early Baart, Eckstein Korn, and Neapolitan were practically free from rust.

Wheat growing (*New Brunswick Agr. Rpt. 1897*, pp. 235-238).—A popular article, encouraging a more extensive and intelligent system of wheat growing and the establishment of a suitable milling industry in New Brunswick. Notes on the culture of wheat are given.

HORTICULTURE.

On the use of commercial fertilizers for forcing-house crops, E. H. JENKINS and W. E. BRITTON (*Connecticut State Sta. Rpt. 1897*, pp. 278-309, fig. 1).—This is a continuation of work reported in previous publications (E. S. R., 8, p. 402; 9, p. 553.)

Tomatoes.—This experiment was made to test still larger quantities of fertilizer chemicals than were used in the previous years, to determine whether the addition of moss peat to the ashes used as a culture medium is advantageous, and to compare the crops grown on rich compost with those grown on ashes and moss peat. The compost used consisted of 2 parts by bulk of turf and 1 part of rotted stable manure.

The ashes were from bituminous coal and were sifted through a screen with 4 meshes to the inch. Two crops of Lorillard tomatoes were grown. The quantities of fertilizers applied per plat, the total yield of fruits, vines, and roots per plat, the average yield of fruit per square foot of bench and per plant, the percentage of perfect-shaped fruits, and the like are given in tables. The growth of the plants and the treatment given them during the tests are briefly noted.

Determinations were made of the nitrogen, phosphoric acid, and potash of the crops of all plats. The results for 4 plats of the second crop are reported. Each plat had an area of 13.87 sq. ft. Two plats were of compost, 1 without the addition of fertilizers, the other fertilized with 17 gm. of nitrogen, 8 gm. of phosphoric acid, and 42 gm. of potash. The other 2 plats were of ashes and peat, 1 fertilized with 65 gm. of nitrogen, 24 gm. phosphoric acid, and 60 gm. potash, the other with 85 gm. nitrogen, 24 gm. of phosphoric acid, and 170 gm. of potash. The fertilizer constituents removed from the soil by the crops on the different plats are shown in the following table:

Nitrogen, phosphoric acid, and potash in tomatoes grown in different culture media.

Fertilizing constituents in the crop.	Coal ashes and moss peat.		Rich compost.	
	Fertilized with 65 gm. nitrogen, 24 gm. phosphoric acid, 60 gm. potash.	Fertilized with 85 gm. nitrogen, 24 gm. phosphoric acid, 170 gm. potash.	Fertilized with 17 gm. nitrogen, 8 gm. phosphoric acid, 42 gm. potash.	Not fertilized.

In fruit.....	17.47	28.32	33.03	23.05
Total potash.....	30.39	65.09	52.43	35.82

The authors give the following summary:

"The yield of tomatoes from benches filled with a rich compost was on the average larger when no fertilizer chemicals were added. The addition of chemicals rather depressed the yield of tomatoes from compost.

"From a mixture of coal ashes and peat with fertilizer chemicals larger crops of tomatoes were produced than from a rich compost of turf and manure in each of the 3 years covered by our experiments.

"Tomatoes are much more productive when grown in a mixture of coal ashes and moss peat than when grown in coal ashes without peat.

"In the tests here reported the plants growing in compost yielded more fruit during the first month than those in ashes and peat. From then on the weekly yield was largest from the plats of ashes and peat.

"The best yields of tomatoes have been from plats of the mixture of coal ashes and moss peat already described, to which had been added per 100 sq. ft. of bench space 6.4 lbs. of nitrate of soda, 1 lb. of dissolved boneblack, and 2.4 lbs. of muriate of potash. The amounts of fertilizer chemicals which can be profitably used depends on the season of the year in which the crop is raised, the watering, and doubtless on other conditions whose effects are not as well understood.

"The crop which is in the house from September to February will not bear as much fertilizer as the following one growing from February to July, because of the smaller amount of sunlight in the first period which the plants can utilize. In the first case the hours of sunlight per day decrease as the foliage increases; in the second case this is reversed.

"Plants which receive large quantities of freely soluble plant food in the soil of ashes and peat have a much less extensive root system than those growing in compost, and when fully grown are likely, in consequence, to wilt more easily."

Carnations.—Experiments were made to determine the fertilizer requirements of carnations grown under glass. Most of the plants were grown in coal ashes and moss peat similar to that used with tomatoes, and some were grown in rich compost. The area of most of the plats was 14.53 sq. ft. The varieties of carnations used were Day-break, William Scott, Alaska, Garfield, and Lizzie McGowan. The plants continued to blossom from December to July. Notes on the growth of the plants are given and a table shows the fertilizers applied to the various plats, the number and weight of cut flowers per plat, the average number of cut flowers per plant, the average weight and diameter of flowers, and the average length of stem, etc.

Analyses were made of young plants like those set in the various plats, of a number of cut flowers of the different varieties grown on the various plats, and of the entire plants, exclusive of flowers. The calculated amounts of nitrogen, phosphoric acid, and potash in the plants set and in the plants and flowers harvested and the amounts applied to the soil are given in tabular form. The data reported are shown in condensed form in the following table:

Nitrogen, phosphoric acid, and potash in carnations grown with different soils and fertilizers.

Culture media.	Number of plants.	Fertilizer constituents per plat.					
		In plants set and in fertilizers applied.			Removed in the plants.

The abnormality known as "sleepy flowers" is noted, and a test of the effect of nitrogenous fertilizers on the prevalence of such flowers is reported. No very close relationship was found⁷⁴ between the amount of nitrogen applied in the fertilizers and the number of "sleepy flowers" produced. The author gives the following summary of the experiments with carnations:

"Carnations have been successfully raised by us in a soil composed of coal ashes and moss peat with commercial fertilizers. The largest yield obtained was an average of 27.3 blooms per plant, or 3,384 blooms per 100 sq. ft. of bench space. The average yield from 7 plats was 25 blooms per plant, or 2,703 per 100 sq. ft. This is an average of Daybreaks and Alaskas, the William Scott variety being excluded from the average. The blooms were of fair size, having an average diameter of 2.1 in.

"The largest crop was gathered from the plat in which 40 gm. of nitrogen, 12 of phosphoric acid, and 60 of potash were mixed with the ashes and peat. This is equivalent to a dressing per 100 sq. ft. of bench space, of 3 lbs. 14 oz. of nitrate of soda, 1 lb. 1 oz. of dissolved boneblack, and 1 lb. 13 oz. of muriate of potash.

"The William Scott variety was badly affected by stem rot and bore many 'sleepy' buds. The Daybreak yielded about 20 per cent more bloom than the Alaska variety, and during December, January, and February yielded twice as many.

"There is no considerable difference in the percentage amount of nitrogen, phosphoric acid, and potash in the fresh-picked blossoms of the 3 varieties tested, the average quantities being, nitrogen, 0.39 per cent, phosphoric acid, 0.15 per cent, potash, 0.68 per cent. Ten thousand Daybreak blooms weigh 191 lbs. and contain 12 oz. nitrogen, 5 oz. phosphoric acid, 1 lb. 5 oz. potash; 10,000 William Scott blooms weigh 187 lbs. and contain 11.7 oz. nitrogen, 4.8 oz. phosphoric acid, 1 lb. 4.6 oz. potash; 10,000 Alaskas blooms weigh 134 lbs. and contain 8.3 oz. nitrogen, 3.4 oz. phosphoric acid, and 14.8 oz. potash.

"A single plat filled with the rich compost . . . did not yield as many blooms as the mixture of ashes and peat."

Radishes.—Cardinal Globe and French Breakfast radishes were grown in ashes and peat and in rich compost, with the addition of various fertilizers. Some of the plats were subirrigated and others surface irrigated. Some of the seed was screened, the small seed being rejected, and some was planted without screening. On part of the plats 3 crops were grown and on part 4 crops. In some cases the fertilizer constituents removed in a crop were added to the soil before the succeeding crop was started, and in some cases no fertilizers were added after the first crop. On part of the plats seed was sown between the rows of half-grown plants in order to hasten the succeeding crop. The fertilizers applied and the yield of radishes are given in tables. The following summary is given:

"By planting between the rows of the half-grown crop 4 crops can be obtained in the time required to raise 3 crops by the usual method of planting.

"There is very little, if any, advantage in subirrigation. In each case save one the weights of the crops were slightly greater from the subirrigated plats, but there was no perceptible difference in the quality of the radishes.

"There was no difference in quality and appearance of the radishes grown in compost and in coal ashes and peat, but those grown in the last-named soil required one or two weeks' less time to reach maturity.

"The crop grown in coal ashes alone was below the average, both in appearance and yield.

"French Breakfast proved inferior to Cardinal Globe as a forcing variety.

"Planting seed selected by sifting out the small seeds (nearly one-third of the whole) made no perceptible difference in either quality or quantity of the crop.

"Very little difference in yield, weight, or time of the maturing of the crop can be ascribed to differences in the quantity of fertilizers used. Good results were obtained by adding to the mixture of coal ashes and peat, for each 100 sq. ft. of bench space, 2.5 lbs. of nitrate of soda, 2.4 lbs. of dissolved boneblack, 1.4 lbs. of muriate of potash. This sufficed for 3 crops of radishes.

"The total yield of radishes (3 crops) from all the plats filled with coal ashes and peat was, for 100 sq. ft. of bench space, 388 bunches (10 in a bunch), or 57 lbs. (tops included).

"The average composition of these radishes was: Water, lost in air drying, 94.35; nitrogen, 0.21; phosphoric acid, 0.062; potash, 0.233.

"According to this year's tests, 1,000 bunches of radishes weigh 147 lbs. and take from the soil 5.6 oz. of nitrogen, 1.4 oz. of phosphoric acid, and 5.4 oz. of potash."

Effects of fertilization on citrus fruits, G. E. COLBY and E. W. HILGARD (*California Sta. Rpt. 1895-1897, pp. 163-181*).—This is a continuation of work previously reported (*E. S. R., 8, p. 691*). A number of orange trees at the southern California substation have been selected for experiments with fertilizers. Analyses of 1 dozen fruits from each tree before fertilizers were applied are reported for future comparison. In regard to the variations in the composition of the fruits of given varieties the report says:

"In the Washington Navels there is a difference of 1.41 between the highest and lowest sugar percentages, and in the Magnum Bonum it is 2.20 per cent. In fact, in all of the varieties but the Homassassas the difference is above 1 per cent. In acid the variation is proportionally about the same. In amount of juice the differences vary from 1.5 per cent in the Mediterranean Sweet to 9.9 per cent in the Parson Brown. In percentage of rind the greatest difference, 10.6, was observed in the Washington Navel. In weight the differences between the averages of the several trees of the same variety was very small in several cases, while in the Pineapple there was as much as 94 gm."

Analyses of oranges from fertilized trees at North Pomona in 1895 are reprinted from the previous report and compared with analyses of fruit from the same place in 1896. After a discussion of the results obtained the report says:

"In general, then, it may be said that the differences shown in the proximate composition of fertilized and nonfertilized fruits in the Richards grove [North Pomona] are not such as may properly be attributed to fertilization, but fall within the limits of normal variation, as shown by the unfertilized fruit of the station orchard."

In regard to the ash of oranges that have received different fertilizers the following summary is given:

"*Nitrogen*.—The lowest percentages were found to be in those lots either unfertilized or to which no nitrogen fertilizer had been applied. It was lowest of all in that on which potash alone had been used. The results indicate that nitrogen was needed in the soil.

"*Total ash*.—The minimum amount of ash was found in the unfertilized lot; next in that fertilized with potash alone; while the highest percentage of ash was obtained in the fertilization with superphosphates.

“*Phosphoric acid*.—As the tables stand, the minimum amount of phosphoric acid in the ash was found in the fruit fertilized with superphosphate alone and the maximum amount where phosphoric acid and potash were used. But if we make the calculation on an even weight instead of on even numbers of each sample, we obtain very different and at the same time very suggestive results.

“In the unfertilized lot we then find 4.73 lbs. of phosphoric acid in 1,000 lbs. of the fruit; in that fertilized with superphosphate alone it is increased to 5.77 lbs., thus indicating a lack of phosphates in the soil. When nitrogen is supplied in the fertilizer the maximum of 6.27 lbs. is reached, thus again showing, as above noted, the need of nitrogen fertilization.

“*Potash*—The maximum of potash in the ash was obtained in the lot from the nitrogen fertilizer and the minimum in that of superphosphate; but, calculated per 1,000 lbs. of fruit, we find that the amount of potash in the ash is nearly the same in that unfertilized and in that fertilized with potash alone, thus showing that potash is not deficient in the soil.”

In continuation of previous work analyses were made of Washington Navel and St. Michael oranges, grown at West Riverside, to study the effect of potash on the fruit. All the fruits tested were produced on soil which had received fertilizers containing phosphoric acid and nitrogen. Part of the trees were also fertilized with muriate of potash. The Navel oranges which were fertilized with potash had a thinner rind and a lower average percentage of juice, as was the case in the previous year's work. They also showed a lower percentage of sugar in the juice, thus contradicting the former conclusion that potash increased the sugar content. The St. Michael oranges fertilized with potash were smaller, thinner skinned, and more juicy than those not so fertilized. There were practically no differences in sugar and acid content between those fertilized with potash and those not fertilized.

Report of injury to fruit trees during the winter of 1895-96, S. A. BEACH and C. P. CLOSE (*New York State Sta. Rpt. 1896, pp. 408-439*).—An unusual amount of injury to fruit buds and fruit trees was caused by the severe winter of 1895-96. Native plums and sour cherries were practically the only stone fruits which were not seriously injured. To learn the relative hardiness of the different varieties of fruits cultivated in the State, correspondence was carried on with fruit growers in all parts of the State. Replies were received from 442 localities. The State was divided into seven fruit districts, and each district is considered separately in discussing the replies. Notes and tables are given showing the varieties most frequently mentioned, the number of times each was mentioned, and the least, greatest, and average percentages of injury reported for each variety.

Observations on cover crops for orchards, S. A. BEACH and C. P. CLOSE (*New York State Sta. Rpt. 1896, pp. 440-445, pls. 2*).—The advantages of cover crops for orchards are briefly noted and an account is given of various cover crops grown in the station orchards in the fall of 1896. The crops were sown August 1. Sainfoin proved undesirable on account of its slowness in starting and its small growth. Cowpeas made a good growth, but were killed by the first frost.

Crimson clover winterkilled and did not do well on hard clay soil. Canada peas and buckwheat and blue peas and buckwheat gave satisfactory results, both mixtures making a good growth and the peas remaining green until winter. The growth of the Canada peas and buckwheat was so great as to interfere with gathering the winter apples. Winter vetch and winter rye formed a perfect mat of vegetation and remained green over winter. They did not grow high enough to interfere with gathering winter fruit. Mammoth red clover formed a dense covering and remained alive over winter, comparing favorably with winter vetch and winter rye. Dwarf Essex rape made a very rank growth, sufficient to interfere with gathering fruit, and seemed to furnish a hiding place for mice, which girdled several of the trees.

Experiments with fruits, J. L. BUDD (*Iowa Sta. Rpt. 1896-97, pp. 127-130*).—The author reports results of introductions of hardy plums, peaches, cherries, apples, pears, and ornamental plants. The Russian plums introduced in 1883 are of greatest value in the south half of Iowa. Some of the Russian cherries have proved superior to other varieties in hardiness and in size and quality of fruit. The Russian apples are of greatest value in the extreme north. "In Minnesota the whole recommended list at present are Russian varieties or Russian seedlings." One of the greatest benefits of the wide distribution of these apples is the opportunity thus afforded for both natural and artificial crosses with old standard varieties and the production of hardy varieties of good quality. Some of the Russian pears have proved perfectly hardy on high ground in northern Iowa. This is especially true of Gakovsky. In southern Iowa Mongolian Snow has done well. The peaches introduced from Asia have given good results in the southern part of the State. Among ornamental plants, many roses, snowballs, spiræas, honeysuckles, lilacs, etc., have proved hardy as far north as Manitoba and Indian Head.

In regard to hybrid fruits and shrubs the author says:

"Our most promising crosses and hybrids are from prepotent ironclad mothers that come near to reproducing from seed. As examples, we crossed the blossoms of the wild rose of east Europe (*Rosa rugosa*) with pollen of our best garden varieties. The results have been a surprise, as in one generation we have secured double flowers and yet retained mainly the vigor and hardiness of the wild rose. With the gooseberry we crossed the blossoms of the wild species of Manitoba with pollen of the Champion. In this case about all the hybrids bear fruit of the size of the Champion, yet we retain mainly the hardiness of bush of the mother plant.

"With the apple we have used prepotent mothers, such as Hibernial, Duchess, and the Anis, and pollen of our best-known winter varieties. As far as yet fruited the fruit largely follows the variety used for pollen, and leaf and tree mainly follow the mother. In our work of hybridizing the plum we have used our best native varieties for mothers and the pollen of the Japan varieties, mainly for the reason that the European sorts do not seem to cross readily with our native species. With cherries and other fruits we have adhered to the same principle of using prepotent ironclad mothers and pollen from the best known sorts."

Report of the horticulturist, H. L. HUTT (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 91-120, figs. 11*).—A report of the work in

horticulture during the year 1897. A list of the varieties of orchard fruits growing at the college is given. Variety tests of small fruits are reported in tabular form, the tests including 13 varieties of red raspberries, 12 black raspberries, 13 currants, 12 gooseberries, and 150 strawberries. The relative yield of the varieties of strawberries is given for the year 1897 and also for 1896. A marked difference was noted between the relative positions of the varieties in the 2 years. In this connection the author says: "The great change in position of many of these [varieties] shows very clearly how little value should be placed upon the results of but a single test. It is only by the average of a number of trials that we can arrive at a reliable estimate of the value of a variety."

Notes are given on 57 varieties of geraniums used for bedding. The following varieties are recommended by the author as being best for bedding purposes: "Scarlet—General Grant, J. J. Harrison, Alfred Tennyson, Alfred Mame, Prokop Daubec; crimson—S. A. Nutt, Sam. Sloan; magenta crimson—Adrien Corret; pink—Madonna, Mons. de la Rue; salmon—Mrs. E. G. Hill, John Good; white—La Favorite, White Swan; bronze-leaved—Maréchal MacMahon; silver-leaved—Mad. Saleroi; golden-leaved—Crystal Palace Gem."

Quantities of mineral matters and nitrogen in violets grown under glass, A. L. WINTON (*Connecticut State Sta. Rpt. 1897, pp. 312, 313*).—An analysis was made of 4 large violet plants, including roots, freed from earth as much as possible, and of 300 flowers as picked for market. The results are shown in the following table:

Percentage composition of violets.

	Plants.	Blooms.
	<i>Per cent.</i>	<i>Per cent.</i>
Water	75.845	88.052
Nitrogen454	.298

Collection of information on the culture of valuable plants on the Caucasus.

III (*Tiflis, 1897, pp. 116; abs. in Selsk. Khoz. i Lyesov., 185 (1897), June, pp. 718, 719*).—This part contains three articles, (1) Tea and the introduction of its culture on the Black Sea coast of the Transcaucasus, by S. N. Timothevif; (2) The culture of *Pistacia vera* on the Transcaucasus, by E. A. Kamenyetski; (3) *Capparis spinosa* and its exploitation on the Caucasus.—P. FIREMAN.

Distribution of seeds, plants, cuttings, etc., E. J. WICKSON (*California Sta. Rpt. 1895-1897, pp. 302-304*).—A report on the seeds, plants, cuttings, etc., distributed by the station (E. S. R., 9, p. 944).

Fruits of the Foothill Culture Substation, C. H. SHINN (*California Sta. Rpt. 1895-1897, pp. 307-324*).—Notes and tabular data are given on varieties of almonds, apricots, plums and prunes, and quinces. Notes are also given on figs, peaches, cherries, olives, walnuts, persimmons, and various small fruits.

Horticulture at the Southern Coast Range Culture Substation, C. H. SHINN (*California Sta. Rpt. 1895-1897, pp. 331-336*).—Notes are given on various fruits, garden shrubs, timber and shade trees, etc. A table is given showing the growth of a number of fruits on hardpan. Smudging orchards to prevent injury from frost was not successful against long-continued and severe frosts.

Report of the horticultural department, J. TROOR (*Indiana Sta. Rpt. 1897, pp. 37-40, fig. 1*).—An outline of the work of the year is given. A variety test of some 20 varieties of potatoes is reported.

Outline of the work of the horticultural department, S. A. BEACH (*New York State Sta. Rpt. 1896, pp. 265, 266*).

Melons, squashes, and vegetables at the Southern Coast Range Substation, A. V. STUBENRAUCH (*California Sta. Rpt. 1895-1897, pp. 343-345*).—Brief notes on muskmelons, watermelons, squashes, pumpkins, cucumbers, tomatoes, eggplants, okra, peppers, lentils, and the like.

Garden vegetables and various trees, E. J. WICKSON (*California Sta. Rpt. 1895-1897, pp. 292-297*).—Reports from correspondents on perennial beans, Ceylon pea, New Zealand spinach (*Tetragonia expansa*), paper mulberry (*Broussonetia papyrifera*), and guavas distributed by the station. The perennial beans are large white beans. Some of them show a tendency to produce two crops a year, and their roots survive ordinary winters in California. The Ceylon pea has large pods, is very prolific, grows well throughout the State, and is of value as a late pea for table or for canning. The New Zealand spinach stands drought well and is useful as a table vegetable and for binding light soils. The paper mulberry is of value as an ornamental plant. In moist ground it suckers abundantly from the roots. Five varieties of guavas from Lucknow, India, sent out for comparison with varieties growing in the State have been found too tender for the climate.

Testing fruits, S. A. BEACH, W. PADDOCK, and C. P. CLOSE (*New York State Sta. Rpt. 1896, pp. 267-300, pls. 5*).—This is a continuation of work reported in the report of the station for 1895. The purpose of variety tests is noted and a table is given showing the number of varieties of each of the various orchard and small fruits now under test at the station, the total number being 3,088. Notes are given on 22 varieties of apples and 5 varieties of grapes, the fruit of 5 of the apples being illustrated. A table shows the yield in 1896, age of trees or grafts, and season of ripening of 261 varieties of apples and 21 varieties of crab apples. A list of 155 varieties of pears, 9 quinces, 20 apricots, 58 cherries, 120 peaches, 197 plums, 240 grapes, and 49 currants growing at the station is given. The yield of 9 varieties of black currants and 18 varieties of red and white currants is given in tabular form.

Almonds, peaches, and nectarines at the Southern California Substation, C. H. SHINN and J. W. MILLS (*California Sta. Rpt. 1895-1897, pp. 391-405*).—This consists of notes on the behavior of varieties of almonds, peaches, and nectarines for a number of years.

Thinning fruit, S. A. BEACH (*New York State Sta. Rpt. 1896, pp. 378-383*).—This article is practically the same as one read before the Hudson Valley [New York] Horticultural Society (*E. S. R.*, 9, p. 448).

Orchard fruits and date palms at the San Joaquin Valley Culture Substation, C. H. SHINN (*California Sta. Rpt. 1895-1897, pp. 353-362*).—Notes and tabular data are given on a considerable number of varieties of apples, pears, almonds, peaches, nectarines, cherries, plums and prunes, and date palms.

Orchard and small fruits, trees, shrubs, and other plants at the Southern California Substation, C. H. SHINN (*California Sta. Rpt. 1895-1897, pp. 368-383, pls. 3*).—Brief notes, accompanied in some cases with tabular data, regarding the behavior of varieties.

Analyses of oranges, lemons, and pomelos, G. E. COLBY (*California Sta. Rpt. 1895-1897*, pp. 161, 162).—Analyses of fruits received from December, 1895, to April, 1897, are reported.

Proximate analyses of prunes, plums, dried fruits, and raisins, G. E. COLBY (*California Sta. Rpt. 1895-1897*, pp. 183-185).—Analyses of various fruits sent to the station for examination.

The causes of "frogging" and "bloating" of prunes, F. T. BIOLETTI (*California Sta. Rpt. 1895-1897*, pp. 254-261, pls. 4).—A reprint of Bulletin 114 of the station (E. S. R., 8, p. 979), with the addition of three plates.

Olives and olive oil, A. P. HAYNE (*California Sta. Rpt. 1895-1897*, pp. 191-193).—A note on the olive industry, with suggestions for its improvement.

Analyses of California olives, G. E. COLBY (*California Sta. Rpt. 1895-1897*, pp. 193-207).—This is a continuation of work recorded in the Annual Report of the station for 1891-95 (E. S. R., 8, p. 701). The data in the previous report are republished, together with analyses for the year 1896. In addition to the record of analyses of the individual samples, the maximum, minimum, and average composition for each variety of olive studied are given.

New apparatus for crushing olives (*California Sta. Rpt. 1895-1897*, pp. 208, 209, fig. 1).—A description of a machine for crushing olives preparatory to the extraction of the oil is published as furnished by the makers.

Examination of sulphured (bleached) fruit (*California Sta. Rpt. 1895-1897*, p. 186).—Sulphured prunes were found to contain 0.33 per cent and raisins 0.36 per cent of sulphuric acid.

Blackberries, dewberries, and raspberries, W. PADDOCK (*New York State Sta. Rpt. 1896*, pp. 344-358).—A reprint of Bulletin 111 of the station (E. S. R., 9, p. 137).

Gooseberries, S. A. BEACH (*New York State Sta. Rpt. 1896*, pp. 300-344, pls. 15).—A reprint of Bulletin 114 of the station (E. S. R., 9, p. 138).

Strawberries, W. PADDOCK (*New York State Sta. Rpt. 1896*, pp. 358-377, pl. 1).—A reprint of Bulletin 109 of the station (E. S. R., 8, p. 786).

The economic position of Russian grape culture and wine making, N. N. KOSHKIN (*Rpt. Min. Agr. and Gort. Estates, Div. Rural Econ. and Agr. Stat. St. Petersburg, 1897*, pp. 91; *abs. in Selsk. Khoz. i Lyesor., 186 (1897), Sept., p. 713*).

Culture of grapes and the contest against phylloxera, P. STROYEV (*Selsk. Khoz. i Lyesor., 186 (1897), Aug., pp. 431-452*).—The author recommends the Russian horticulturists to employ the capital which they spend in combating the phylloxera in Bessarabia in introducing American vines which are not affected by the phylloxera.—P. FIREMAN.

Memoranda on wine, table, and raisin grapes, F. T. BIOLETTI (*California Sta. Rpt. 1895-1897*, pp. 245-253).—This is a summary of the results obtained with various varieties of grapes at the several substations of the State, the details of which have been reported in previous viticultural reports.

California walnuts, almonds, and chestnuts, G. E. COLBY (*California Sta. Rpt. 1895-1897*, pp. 142-159).—A reprint from Bulletin 113 of the station (E. S. R., 8, p. 786) rearranged and with somewhat more extensive notes and the addition of a table comparing the composition of fresh almond hulls with that of green alfalfa.

The bleaching of nuts by dipping, E. W. HILGARD (*California Sta. Rpt. 1895-1897*, pp. 159, 160).—Reprinted from Bulletin 113 of the station (E. S. R., 8, p. 788).

FORESTRY.

A report of forestry substations, C. H. SHINN (*California Sta. Rpt. 1895-1897*, pp. 406-426, pl. 1).—The author gives a report of the present condition of the forest substations at Chico and Santa Monica. Brief notes are given on the general culture pursued at the Chico station and comparisons made with the two pine plantations of *Pinus resinosa* and

P. sylvestris. Both blocks were set in 1889-90. The *P. resinosa* trees average 17 ft. in height and the Scotch pine about 13 ft.

Observations were made by an inspector of the young trees in the Sierra showing that seedling pines and other conifers wherever protected from sheep and cattle form close thickets in a few years. During the winter of 1895-96, which was a very severe one, quite a number of Eucalyptus and Acacia trees were destroyed, as well as a number of carob trees. The heat of the following summer destroyed quite a number of trees, among which were specimens of *Abies*, *Sassafras*, and *Cephalotaxus drupacea*. The Japanese oaks have also proved unadapted to this region. The rate of growth of trees in the forest is shown in a table compiled from records made by the foreman of the station. The growth of 9 specimens of conifers and 4 deciduous trees are tabulated as follows:

Statistics of tree growth, 1894 to 1896, inclusive.

Name.	Growth, 1894.		Growth, 1895.		Growth, 1896.	
	Height.	Circumference.	Height.	Circumference.	Height.	Circumference.
	Feet.	Inches.	Feet.	Inches.	Feet.	Inches.
<i>Chamaecyparis lawsoniana</i>	8	12	10	12	13	15
<i>Catalpa speciosa</i>	16	16	21	21	26	25
<i>Negundo californica</i>	15	11	18	12	24	18
<i>Pinus austriaca</i>	5	6	9	10	14	14
<i>P. insignis</i>	11	9	13	11	19	19
<i>P. resinosa</i>	7	7	11	9	17	13
<i>P. sylvestris</i>	7	9	9	10	13	11
<i>Pseudotsuga taxifolia</i>	3½	Not taken.	5	4	9½	7
<i>Sequoia gigantea</i>	13	16	17	25	21	31
<i>S. sempervirens</i>	6	Not taken.	13	10	17	13
<i>Cupressus sempervirens</i>	15	8	20	12	22	16½
<i>Pantonia imperialis</i>	19	19	21	23	24	30
<i>Juglans californica</i>	12½	14	18	20	23	25

A list of trees and number of species being tested at the station is given. The general condition of the Santa Monica station is described and temperature and rainfall records for the years 1893-1897 are included, together with descriptive notes and improvements.

Measurements have been made of the larger Eucalyptus trees in the main grove and the results were tabulated, showing the growth of the trees for the years 1894, 1895, and 1896. The trees were mostly planted in 1889 and 1890, and in many cases have attained very considerable size. One specimen of *Eucalyptus globulus* was measured in 1896, being reported as 46 ft. high and 19 in. in diameter, with a spread of top of 28 ft.

The flowering time of the various species of Eucalyptus are given, the lengths of their blooming period, and their possible use as bee pasturage. A table is given in which the comparative resistance of several of the more common species of Eucalyptus is shown. The figures given seem to indicate that *Eucalyptus globulus* and *E. corynocalyx* are among the most resistant. Brief descriptive notes are given of some recent additions to the arboretum, among which are some Japanese bamboos, *Morus multicaulis*, various willows, etc.

Forestry plantations, J. L. BUDD (*Iowa Sta. Rpt. 1896-97, pp. 126, 127*).—The author reports upon the present condition of forestry plantations, the trees of which were planted from 15 to 21 years ago on both high and low lands. The land selected was 4 knolls of thin soil, with parts of the valley between dry enough for plowing. The trees were planted 4 ft. apart each way and cultivated until the tops shaded the ground fairly well. On knoll 1 the box elders and catalpas have, as a rule, made scrubby, dwarfed growth. Specimens of black oak 1 ft. above the ground are 43 in. in circumference, Riga pine 43, basswood 39, Austrian pine 36, red cedar 23, catalpa 21. In the case of the catalpa tree the trees measured were exceptional; in the other cases average trees were taken. Upon the low ground at the base of this plat box elder, catalpa, basswood, and hard maple made a large, even growth.

The second portion of the plantation was devoted largely to white pine and European larch, alternated with box elder and green ash. On the hilly ground the white pine has grown very successfully, many of the trees being 44 in. in circumference and 50 ft. in height. The best larches measure 31 in. in circumference and are as high as the pines. The box elder and ash, as a rule, have been crowded out except in the lower grounds. The white pine and larch on the low land are equal in size and stand to those on the hill.

The third part of the plantation was planted mostly with black walnut and butternut, with some box elder, white elm, green ash, and black wild cherry. In the bottom lands the black walnuts average 50 ft. in height, with stems 29 in. in circumference. The only trees not crowded out by their growth is the white elm, which in height and vigor of growth is about equal to the black walnut. On the hilly part of the plantation the only thrifty trees are the European larch and the black wild cherry. At the time of the planting the belief was common that the butternut was a high-land tree, and no specimens were planted in the low lands. On the hills most of the trees are either dead or their tops are dying.

In the fourth part of the plantation green ash was planted exclusively, and with 20 years' growth the largest trees on the low land are 25 in. in circumference. Upon the high ground the trees stand much better than where alternated with black walnut, white pine, and larch, but they are of small size, showing that they should have been thinned at least 10 years ago.

Of the conifers planted on the college campus during the past 20 years the species that have remained thrifty in isolated positions in blue-grass sod are white, Black Hills, silver, and Douglas spruce; Douglas and concolor fir; and white, Black Hills, dwarf mountain, red, riga, and some specimens of Austrian pines. Black and Norway spruce, Scotch pine, common fir, and American and European larch do not withstand drought in isolated positions as well as in timber plantations.

Timber and shade trees, C. H. SHINN (*California Sta. Rpt. 1895-1897*, pp. 336-338).—The author in a brief report gives a limited list of shade, ornamental, and timber trees which 8 years of experience has shown to be well adapted to the lands east of the Salinas. The important factors to be considered in determining the hardiness are ability to resist drought, thrive on poor soils, and capacity to penetrate hard-pan of various depths and various degrees of solidity.

Among the trees best adapted to these conditions are some of the oaks, particularly *Quercus pedunculata*, *Q. douglasi*, and *Q. lobata*. Of these the English oak, *Q. pedunculata*, was by far the best. Among other deciduous trees of merit in this respect are mulberries, box elders, and black locusts. Notes are also given on the mulberry tree, several species of pine, casuarina, 3 species of fir, *Cedrus deodar*, *Eucalyptus globulus*, *Paulownia imperialis*, and Osage orange.

Brief review of the activity of the forestry department during the two years from June, 1895, to June, 1897 (*Selsk. Khoz. i Lycesor.*, 186 (1897), Aug., pp. 241-314).

The influence of local conditions on tree growth, W. GILL (*Jour. Agr. and Ind. South Australia*, 1 (1898), No. 9, pp. 675-677).

SEEDS—WEEDS.

Tests of the vitality of vegetable seeds, E. H. JENKINS (*Connecticut State Sta. Rpt. 1897*, pp. 383-391).—The author reports on tests of a number of vegetable seeds. The tests were conducted in accordance with the rules adopted by the Association of American Agricultural Colleges and Experiment Stations, as published in Circular 34 of this Office (E. S. R., 9, p. 143). Six hundred and fifty-five samples of seeds were tested for their vitality, and it was found that on an average the samples of beet, cabbage, and carrot seed which were over one year old had a higher germinative capacity than new seed. This fact was probably due to the generally better quality of the previous years' seed. The author states that the results of several years' tests would probably show that, taking one year with another, new seed would sprout better than seed one or more years old.

A series of tests was made of the vitality of onion seed, 131 samples of seed from the crops of 1896 and 1897 raised in Connecticut, Rhode Island, and California being compared. As a rule the vitality of seed decreases with age, but there were some cases in which 2-year-old seed sprouted better than that of the new crop. The vitality of the California-grown seed was considerably higher than that of the Connecticut. Forty-four samples of Connecticut-grown seed of the crop of 1896 were tested and gave an average of 72.4 per cent germination. Thirty-nine samples of seed from the crop of 1897 gave an average of 77.9 per cent. The crop of 1895 gave, as an average of tests, a germinative capacity of 85.5 per cent. The average weight of onion seed and the germinative ability of different varieties are given. The author

has tabulated the results of his experiments, showing the usual data of such experiments.

Seed testing: Its importance, history, and some results, C. R. BALL (*Iowa Sta. Rpt. 1896-97, pp. 161-175*).—The author gives a brief review of the importance of seed testing, together with an historical sketch of seed control in Europe and this country. He reports at some length seed tests made at the station in 1897. The seeds were bought in February from five different seedsmen, and were supposedly of the crop of 1896. Twenty varieties of seeds were purchased and tested in the spring of the year and again in the fall, the seed being taken from the same packages in each case. The vitality tests showed, for the most part, that the seed were fairly good but considerably below the recognized standard. Most of the tests showed a declining vitality, but in the case of the cucurbit seeds in nearly every instance the autumn tests gave a higher percentage of germination than those obtained in the spring.

Reports of the Danish Markfrökontor (seed house) for 1896 and 1897 (*Copenhagen, 1897, pp. 32; 1898, pp. 40*).—The twenty-fourth and twenty-fifth annual reports of "Markfrökontoret," containing many papers on seeds and farm crops.

Report of the seed-control station in Lund (Sweden) for 1897, B. JÖNSSON (*Malmö, 1898, pp. 29*).

Influence of dividing mother beets on seed production, F. LUBANSKI (*Bt. Zuckerrubebau., 5 (1898), Nos. 6, pp. 86, 87; 7, pp. 97, 98*).

On the methods of testing and estimating the value of beet seed, R. HARTLEB and A. GILLMEISTER (*Jour. Landw., 46 (1898), No. 2, pp. 185-206*).

The germinative power of grain immersed in water, H. COUPIN (*Jour. Agr. Prat., 62 (1898), No. 21, p. 752*).—Results of experiments with various kinds of seeds are reported. When immersed in running water for 48 hours 70 per cent of buckwheat, 100 of wheat, 89 of maize, and 96 of peas germinated. When immersed for the same time in standing water the percentage of germination was 52, 97, 80, and 85, respectively.

Concerning the artificial drying of seed of cereals with reference to their germination, F. NOBBE (*Mitt. Deut. Landw. Gesell., 12 (1897), No. 14, pp. 185, 186*).

American clover seed in Austria-Hungary, C. B. HURST (*U. S. Consular Rpts., 1898, No. 212, pp. 120-122*).—A brief account is given of the attempt being made to exclude American clover seed from Austria-Hungary. The basis of the exclusion is the danger from the presence of dodder seed (*Cuscuta epithimum*).

Analyses of seeds, A. K. SABANINE (*Contrib. Agr. Lab. Univ. Moscow, 1896, pp. 47; abs. in Selsk. Khoz. i Lyesor., 185 (1897), Apr., p. 242*).—Of the various conclusions drawn by the author from his analyses of the seeds of different field plants grown in Russia the most interesting is that the nitrogen content of grains of rye increases as the place of growth proceeds from west to east or as the climate becomes more and more continental—a phenomenon already observed by other investigators in regard to wheat, barley, and millet. The author also noticed that the greater the amount of nitrogen in the rye grains the smaller the amount of ash.—P. FIREMAN.

Seed breeding, W. W. TRACY (*Amer. Florist, 13 (1898), No. 520, pp. 1251, 1252*).

Note on the distribution of *Pseudocommis vitis* by the winds, M. BÉLÈZE (*Bul. Soc. Mycol. France, 14 (1898), No. 1, p. 27*).

Clover dodder, H. KRAUT (*Deut. Landw. Presse, 25 (1898) No. 26, p. 287*).

DISEASES OF PLANTS.

Report of the mycologist, F. C. STEWART (*New York State Sta. Rpt. 1896, pp. 447-521, pls. 3*).—The author gives a review of the year's work, the most of which has been published in bulletin form.

Notes are given on several miscellaneous plant diseases that have been noticed by the author. A disease of turnip leaves which was due to *Macrosporium herculeum* is figured and described at some length. The fungus produces circular, brittle, dead spots on the leaves and when the spots are numerous the leaves wither and fall off. While many of the species of *Macrosporium* are saprophytic, this species, the author states, is undoubtedly a parasite. A similar disease is reported on the foliage of horse-radish during the summer. However, it is not thought that either on the turnip or horse-radish will sufficient injury be done to warrant the expense of spraying.

A blight of corn leaves, the primary cause of which is attributed to the parasitic fungus *Helminthosporium inconspicuum*, has caused considerable injury in some localities. The diseased leaves have somewhat the appearance of having been frosted. If the surface of the leaves beneath the diseased spots be examined it will be found covered with a delicate, olive-green mold. This disease is said to attack both sweet and field corn. There is a disease of sweet corn due to bacteria which might be mistaken for this disease. The latter disease makes its appearance early in the season, while *Helminthosporium inconspicuum* usually does not appear until August. No practical remedy is suggested. The bacterial disease has been fully described in Bulletin 130 of the station (E. S. R., 9, p. 1056).

The author describes an injury of the foliage of Norway maples which is attributed to the action of dry winds, the entire foliage of some trees being scorched as if by fire or as though killed by a heavy frost. For a period of about a week previous to the appearance of the injury the temperature had been unusually high and during the last three days strong dry winds had blown steadily from the West. The explanation of the injury is that it is due to a disturbance in the transpiration of the trees. In addition to the Norway maple, white pine, pear, and apple trees were slightly injured by the same cause.

Brief notes are given on a leaf-spot disease of linden due to *Cercospora microsora*, a leaf spot of apples due to *Phyllosticta limitata*, two diseases of sunflowers caused by *Septoria helianthi* and *Puccinia helianthi*, a disease of the horse-chestnut caused by *Phyllosticta sphaeropsoides*, a sycamore disease caused by *Glucosporium nervisequum*, asparagus rust, and a clover rust which are described in more or less detail, all of them having proved injurious during the year. The author also reports the occurrence or additional localities for *Exoascus cerasi*, *Exobasidium peckii*, and *Ramularia cylindriopsis*.

Reports are made on the work in combating carnation rust, which was published as Bulletin 100 of the station (E. S. R., 8, p. 238), potato

diseases on Long Island in the season of 1895, which appeared originally as Bulletin 101 (E. S. R., 8, p. 234), and the cucumber flea-beetle as the cause of "pimply" potatoes, which has previously been published as Bulletin 113 of the station (E. S. R., 9, p. 156).

The mildew of Lima beans, W. C. STURGIS (*Connecticut State Sta. Rpt. 1897*, pp. 159-166, figs. 1).—Investigations are reported in which the author sought to find the manner in which the bean pods are infected by the mildew of Lima beans (*Phytophthora phaseoli*). It was thought probable that preliminary information as to the means by which the disease is spread might result in securing means for its prevention.

Studies of the flower show that bees are the source of dissemination of the fungus spores and that the first attack of the fungus is at two points, namely, the style and the base of the ovary, where the bee, searching for nectar, touches the more moist and delicate tissues of the flower. In most cases where young diseased pods were examined it was found that the infection first appeared at the base or tip—very rarely in the middle.

The author also shows that wind plays an important part in the dissemination of this mildew. An experiment was conducted in which mildewed pods were brought from a distance and the spores allowed to infect the surface of sound, nearly ripe pods at one end of a row of pole Limas. Within a few days the mildew made its appearance on these infected pods, and within two weeks (the prevailing winds having been in that direction) the disease had spread from one end of the row to the other.

While from the nature of the disease it would seem probable that the use of fungicides would present many difficulties, yet from experiments in which Bordeaux mixture, ammoniacal copper carbonate solution, sulphur, and potassium sulphid were used it appeared that when three applications of Bordeaux mixture was followed by two applications of ammoniacal copper carbonate solution the amount of the disease was greatly reduced.

The conclusions drawn from the experiments with fungicides show that even in a season most favorable for the Lima bean mildew a thorough treatment of the vines with Bordeaux mixture will insure a crop. The selection of well-drained land and a light soil, reducing the number of vines in the hill, and planting the poles erect will insure conditions as little favorable to the development of the fungus as possible.

On the cause and prevention of a fungus disease of the apple, W. C. STURGIS (*Connecticut State Sta. Rpt. 1897*, pp. 171-175).—During the autumn of 1896 a rather peculiar disease of Rhode Island Greenings and Newtown Pippins was observed. It was characterized by blotches, circular in outline, pale at first and later becoming sooty black and exhibiting under a lens a radiating structure. The individual blotches measured from a quarter to a half inch in diameter, in many cases coalescing and covering the surface of the apple with a sooty coating.

The fungus growth seems to attack the fruit late in the season and to be strictly superficial, but aside from the unsightly condition of the fruits apparently producing no serious injury. The author is inclined to believe that the disease is due to the fungus which has been determined as *Dothidea pomigena*, but a spot disease of Baldwin apples from the Vermont Station which differed widely in appearance has been determined as due to the fungus named. In the author's opinion the Vermont fungus is entirely different.

Experiments with Bordeaux mixture show that if this fungicide is applied at intervals of two weeks from the middle of June to the middle of August it will entirely prevent the appearance of the sooty fungus.

Although apparently occurring principally on Rhode Island Greenings and a few other varieties, it is probable that the fungus will, under favorable conditions, attack most varieties of apples and pears, but all observers agree in stating that it may be controlled by the use of Bordeaux mixture.

Preliminary investigations on a disease of carnations, W. C. STURGIS (*Connecticut State Sta. Rpt.* 1897, pp. 175-181).—The variety of carnation known as William Scott grown in the station greenhouse was observed as exhibiting a marked diseased condition. The disease appeared first as a yellowing of the lower leaves, which later became dry and dead. As the disease progressed, the whole plant became involved and was ultimately destroyed. The disease, which is properly known as "die back" or "stem rot," has been determined as due to a species of *Fusarium* which gains access to the tissues at or just below the surface of the soil. The mycelium accumulates in the water ducts of the stem, thus preventing the free transfer of water. The author discusses the relationships of this form with other species and thinks probably it is identical with *Fusarium nircum*, described by E. F. Smith¹ as the wilt fungus of watermelon and allied plants.

There is a strong probability that the disease may be communicated by cuttings and that the spores of the fungus are capable of retaining their vitality for several months, living over winter in the earth. Where practicable, as in greenhouses, etc., sterilizing the soil by means of steam or hot air would be effective in preventing attacks of the fungus. In sterilized soil the only possible source of contamination would be through the introduction of diseased cuttings. Certain varieties are more susceptible to the disease than others, the variety William Scott being one of those most subject to the attack. The immediate removal and destruction of all plants showing diseased symptoms are recommended.

Some diseases of olives, F. T. BIOLETTI (*California Sta. Rpt.* 1895-1897, pp. 234-236, pl. 1).—The author briefly describes some of the more troublesome diseases of olives that have recently come to his observation. In one of these the olives, from their outside appearance, seem to be perfectly healthy, but on being cut open show black spots and little

cavities near the pit. Where the disease has progressed further sunken areas appear on the outside, while inside the fruit the black spots are larger, often extending all around the pit. As the disease progresses the fruit gradually shrinks and dries up, the skin remaining unbroken. Microscopic examination of these parts showed the presence of large numbers of motile bacteria. Pure cultures were made of the bacterium and its characteristics were partly determined, as follows:

"It grew slowly in beef broth and rapidly in a decoction of vine wood. On peptone meat gelatin its growth was small and slow. On the vine-wood decoction, solidified with 12 per cent of gelatin, it grew rapidly. In puncture cultures it made a tack-shaped growth, white, granular, and raised top; in streak cultures it made a granular growth, consisting of small, round, white colonies. On potato it made a light, yellowish growth and darkened the potato. It was motile, aerobic, and did not color nor liquefy the gelatin. In form it was a small bacillus with rounded ends, 1 to 1.7 μ by 0.7 μ , generally single or in pairs."

Inoculations with pure cultures gave negative results. The disease does not seem to affect the fruit nor to injure it appreciably until it commences to soften. It does not affect the oil-making varieties and is probably not dangerous. The fruit on affected trees should be picked early and used for pickling.

Another troublesome disease of the olive is figured and described. This disease begins at the apex and works toward the stem end of the fruit. When the olives are cut one-sixth to one-third seems to be brown and partially dried up. Numerous cultures made of the mycelial threads taken from the interior of the diseased olives developed two fungi, one a *Macrosporium*, the other an *Alternaria*. Both fungi are figured and described at some length. The author suggests that spraying the trees with Bordeaux mixture would probably prevent the spread of the disease. As it seems so far to be confined to the variety known as Nevada-dillo blanco, this variety should be omitted in planting where the disease is found to be prevalent.

Alfalfa leaf spot, R. COMBS (*Iowa Sta. Rpt. 1896-97, pp. 155-160, figs. 4*).—The author gives an illustrated description of alfalfa leaf spot, caused by *Pseudopeziza medicaginis*, and reports a number of experiments made to determine the method of infection and also the parts of the plant subject to attack. His experiments show that the spores of the fungus may be carried by the air and that the disease is strictly local in its attack, the mycelium being confined to a limited space on the leaf. The author recommends the burning of all refuse in the field, since the disease readily survives the winter. Frequent cutting of the crop is also effective in holding the disease in check. It is thought advisable, where seed is obtained from suspected or known infested regions, that it should be soaked in a 10 per cent solution of copper sulphate before sowing.

Report of the botanical department, J. C. ARTHUR (*Indiana Sta. Rpt. 1897, pp. 25-34*).—The author gives a brief résumé of various lines of investigation carried on during the year. The experiments

which were begun in the greenhouse in the winter of 1895-96 with formalin for the prevention of potato scab have been continued in the field, and Bulletin 65 of the station issued on the subject (E. S. R., 9, p. 456). Notes are given from correspondence with different individuals relative to the use of formalin as a preventive of potato scab, from which it appears that if this fungicide is properly applied and the seed potatoes planted in uninfested soil a clean crop of potatoes will be secured. Studies have been made on the growing of lettuce in the greenhouse, and the most important conclusions have been embodied in Bulletin 66 of the station (E. S. R., 9, p. 1047). Observations and studies on corn smut have been continued.

Continued observations have been made on a peculiar sugar destroying disease of the sugar beet, which was previously reported in Bulletin 39 of the station (E. S. R., 3, p. 853). The bacterial nature of the disease has been confirmed and a future publication is promised of the results of the investigation.

Investigations have been continued in the growing of roses and cineraria, and some notes are given of studies on the proper food of plants.

Experiments have been continued on the effect of size of seed on production, peas and beans being used. The author has attempted to ascertain the law of increase in size when brought about solely by selection of the largest seed through a series of generations.

Subwatering for greenhouses and outside storage has been under consideration.

Report of the bacteriologist, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 121-128, figs. 2*).—A report is given of the routine work in connection with the agricultural college and of an experiment conducted to ascertain the effect of spraying Bordeaux mixture on foliage. Eight seedling pears and two each of peach and quince were sprayed with Bordeaux mixture containing different amounts of lime. The plants were potted and kept in greenhouses, so that uniform conditions could be maintained. Four applications of the fungicide were made and specimens of the leaves examined. Later three more sprayings were given. The most noticeable feature, as shown by microscopic examinations of the leaves, was the increase in number of chlorophyll granules both in the palisade cells and in the spongy parenchyma of the sprayed leaves. In many cases the treated leaves showed the presence of a third layer of palisade cells more or less continuous. Measurements of the thickness of the leaves were made by means of a micrometer, and in every case but one there was an increased thickness, due to spraying. When an excess of lime was used the leaves were thicker than when a smaller quantity was used. The addition of lime seemed to give the foliage increased vigor. The author thinks that it would be advisable to use larger amounts of lime in the preparation of Bordeaux mixture. The increased thickness of the leaves seems to be due to an increased development of the palisade layer of cells.

On the prevention of leaf blight and leaf spot of celery, W. C. STURGIS (*Connecticut State Sta. Rpt. 1897, pp. 167-171*).—Notes are given on leaf blight and leaf spot of celery caused by *Cercospora apii* and *Septoria petroselinii apii*. In the Annual Report of the station for 1892 (E. S. R., 4, p. 929) the beneficial effect of sulphur for the prevention of this disease was pointed out, but the investigations of the Rhode Island Station¹ and recent investigations by the author indicate that methods of cultivation exert a very considerable influence on the disease, the level culture seeming to make the plants more liable to infection than the old method of trench culture. The author agrees with the conclusions of the Rhode Island Station, and states that the objections to the level culture may be at least partially removed by mulching heavily between the rows of celery.

Experiments are reported with fungicides in which Bordeaux mixture, potassium sulphid, ammoniacal solution of copper carbonate, and sulphur were tested for the prevention of these diseases. It appeared that sulphur applied as a dry powder was superior to any of the other fungicides. Its effect in checking the spread of the blight in the storage house has not been determined.

Plum leaf spot, S. A. BEACH (*New York State Sta. Rpt. 1896, pp. 384-401, pls. 5*).—The experiments here reported are in continuation of those given in Bulletin 98 of the station (E. S. R., 8, p. 139), attempts being made to control the plum leaf spot by spraying with fungicides. As a result of this year's investigations the author recommends spraying trees three times with Bordeaux mixture, the first application being made about May 25, or about 10 days after the blossoms have fallen, the second about 3 weeks later, and the third about 4 weeks after the second.

Prevention of fungus diseases in cherry orchards, S. A. BEACH (*New York State Sta. Rpt. 1896, pp. 402-407, pl. 1*).—A report is given of experiments conducted for the prevention of leaf spot and the fruit rot of cherries, which are in continuation of those reported in Bulletin 98 of the station (E. S. R., 8, p. 139). In these experiments eau celeste soap mixture was compared with Bordeaux mixture. In 1895, while the diseases were prevented to some extent by the use of fungicides, the foliage was seriously injured, the eau celeste being most injurious. In the experiments in 1896 no injury resulted to the foliage sprayed with Bordeaux mixture, even when the trees were thoroughly drenched with the solution. The results of the two years' work did not give conclusive evidence as to the best lines of treatment of leaf spot on cherry trees, consequently no definite treatment is recommended.

A steam sterilizer for soils, W. E. BRITTON (*Connecticut State Sta. Rpt. 1897, pp. 310-312, pl. 1*).—The author figures and describes an apparatus designed for the sterilization of soil by steam, the object being to rid the soil of fungi, fungus spores, nematodes, etc. It was

¹ Rhode Island Sta. Bul. 44 (E. S. R., 9, p. 146).

found that in soil kept in the apparatus for one hour the nematodes were destroyed, as well as many fungus germs. In order to secure absolute sterility from bacteria and other fungi a much longer exposure would be required. The steamed soil was also almost wholly free from live weed seeds, while untreated soil was considerably affected by them.

Blight and other plant diseases, C. S. CRANDALL (*Colorado Sta. Bul. 41, pp. 21*).—The author has given compiled notes on the cause and means of prevention of the fire blight of the pear and apple. Notes are also given on mechanical injuries to which fruit trees are subject, as well as some of the more common fungus diseases, such as leaf blight or rust of strawberries and orange rust, and anthracnose of blackberries and raspberries.

Injurious fungi, J. H. PANTON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, p. 23*).—Brief notes are given on some of the more injurious fungi which affect garden and orchard products. The use of Bordeaux mixture is recommended for their prevention.

The most important diseases of our cultivated plants caused by parasitic fungi. I. The diseases of cereal grasses, V. K. VARLIKII (*St. Petersburg, 1897, pp. IV+37, figs. 19; abs. in Selsk. Khoz. i Lyesor., 187 (1897), Nov., p. 449*).

Album of aquarelle drawings of A. N. Myasoyedov of the most injurious parasitic fungi of trees and of the injuries to the wood of the principal Russian forest trees, I. P. BORODIN, editor (*St. Petersburg, 1896, 10 tables in folio with explanatory text; abs. in Selsk. Khoz. i Lyesor., 187 (1897), Nov., p. 441*).

Brief sketch of mycology, with notes on the fungi most injurious to agriculture and forestry, I. P. BORODIN (*St. Petersburg, 1897, pp. 4+231+VII, figs. 232; abs. in Selsk. Khoz. i Lyesor., 187 (1897), Nov., p. 440*).

On certain diseases of fungal and algal origin affecting economic plants in India, D. D. CUNNINGHAM (*Sci. Mem. Med. Officers of Army of India, 1897, pt. 10, pp. 95-130*).

On the sudden destruction of sugar cane in East Java by the "Dongkellan" disease, KOBUS (*Arch. Java Suikerind., 5 (1897), pp. 821-826; abs. in Centbl. Bakt. u. Par., 2. Abt., 4 (1898), No. 8, p. 348*).—This disease is usually attributed to *Marasmius sacchari*.

Investigations on some sugar-cane diseases (*Meded. Proefstat. Suikerriet W. Java, 1897, No. 30, pp. 5; abs. in Centbl. Bakt. u. Par., 2. Abt., 4 (1898), No. 8, p. 347*).

Investigations of *Phytophthora infestans*, a cause of potato rot, L. HECKE (*Jour. Landw. 46 (1898), Nos. 1, pp. 71-74; 2, pp. 97-143, pls. 2*).—The author reports studies on the development of the fungus, paying considerable attention to the method of entrance into the host, spread of the disease, method of wintering the fungus, and means for combating the disease.

Remarks on sugar-beet diseases in the Province of Saxony during 1897, M. HOLLRUNG (*Ztschr. Ver. Dent. Zuckerind., 1898, No. 507, pp. 353-359*).

Potash manuring, especially with potassium carbonate, as affecting beet sickness, M. HOLLRUNG (*Ztschr. Ver. Dent. Zuckerind., 1898, No. 507, pp. 343-353*).

The anthracnose of ficus leaves, B. D. HALSTED (*Amer. Florist, 13 (1898), No. 521, p. 1287, figs. 2*).—The author figures and describes an anthracnose (*Glucosporium elasticae*) of the leaves of rubber plants. The treatment recommended is the removal of all spotted leaves. The same or a similar fungus is said to attack crotons, dracaenas, and other plants, and it is liable to spread through a greenhouse unless checked.

The fusarium disease of potatoes, WEHMER (*Ztschr. Spiritusind., 21 (1898), No. 48-49*).

A reply to Frank's article on "A new potato disease," P. SORAUER (*Centbl. Bakt. u. Par., 2. Abt., 4 (1898), No. 6, pp. 236-242*).

The mildew of *Syringa vulgaris* in North America, P. MAGNUS (*Ber. Deut. Bot. Gesell.*, 16 (1898), No. 3, pp. 63-70, pl. 1).—The author calls attention to a common *Microsphaera* on *Syringa* in this country which seems to have been mistaken for *M. friesii*.

The carnation fairy ring fungus, B. D. HALSTED (*Amer. Florist*, 13 (1898), No. 520, p. 1256, fig. 1).—This disease is attributed to attacks of *Heterosporium echinulatum*. It may be controlled by spraying plants with a solution of potassium sulphid.

Specimens of diseased plants, etc., F. T. BIOLETTI (*California Sta. Rpt.* 1897-1897, pp. 237-242, pl. 1, fig. 1).—Notes are given on a number of diseased plants which were sent in for identification. The cause of the trouble in each case is given and suggestions offered in many cases for the prevention of the disease. One of the most serious diseases reported upon is the tuberculosis of olives, which has been reported upon in Bulletin 120 of the station (E. S. R., 10, p. 55).

Literature of fungus diseases, W. C. STURGIS (*Connecticut State Sta. Rpt.* 1897, pp. 182-222).—A provisional bibliography of the more important works published by the U. S. Department of Agriculture and various agricultural experiment stations of the United States from 1887 to 1897, inclusive, on fungus and bacterial diseases of economic plants. The general arrangement of the subject is as follows: The host plants are arranged alphabetically, and under the name of each host plant are also arranged alphabetically the common names of the fungus diseases recorded as affecting that plant. References to descriptions and illustrations either of the fungus itself or of its effect upon the host plant follow, and finally suggestions for treatment if any have been recommended. The author has devoted considerable study to the subject, and has listed only those publications which he is convinced give the best descriptions, illustrations, or treatments which have been tested.

In addition to the bibliography outlined in the preliminary paragraph, a bibliography of 100 publications (mostly foreign) relating to plant disease is given.

Treatment for preventing smut, C. A. ZAVITZ (*Ontario Agr. Col. and Expt. Farm Rpt.* 1897, p. 170).—Reports the beneficial use of the hot-water treatment of seed wheat for the prevention of smut.

Remedy for fungi and insects, C. W. WOODWORTH (*California Sta. Rpt.* 1895-1897, pp. 213-233).—The author popularly describes injurious fungi and insects and suggests remedies for the prevention of their attacks. Numerous fungicides and insecticides are described and formulas given for their preparation.

Notes on the preparation of fungicides, L. DEGRULLY (*Prog. Agr. et Vit.*, 29 (1898), No. 19, pp. 577-581).—Formulas are given for the preparation of a number of the better known and most efficient fungicides and explicit directions for their compounding.

ENTOMOLOGY.

Report of the apiculturist, R. F. HOLTERMANN (*Ontario Agr. Col. and Expt. Farm Rpt.* 1897, pp. 235-244, figs. 3).—The report is of a miscellaneous nature, the more interesting facts of which are the success in the plan of cutting the combs of the brood chamber, thus allowing of ready communication between the different parts of the clustering swarm, as described in the last report; the confirmation of experiments on foul brood made during the previous year, demonstrating that the germs are completely destroyed by the process of foundation making; the failure of Carniolans to produce satisfactory combs unless given full sheets of foundation; the fact that in healthy cellar wintering there is no brood rearing, and that stores in the brood chamber may be moved to the supers to such an extent as to greatly injure the quality of the honey in the latter.

An experiment is noted on the value of pure air ventilation and artificial heat in wintering. A cellar was partitioned off into four rooms, at the end of one of which was placed a stove, the pipe from which ran through all four rooms. The temperature on February 14 of room 1 was 38° F., rooms 2 and 3, 40°, and room 4, 42°. The bees in the first cellar were much the most quiet. In the last they were the most restless all through the winter. The whole of the 300 colonies, with the exception of several starved and mice-destroyed colonies, all came through successfully. Although the passage of air from room to room is not desirable, the beneficial feature of currents of pure air and the maintenance of a steady low temperature is demonstrated.

Other subjects noted are the superiority of a bee space between sections in supers; the success of moving bees to fall pasture; the importance of filling sections to sides and bottom with foundation, thus preventing the formation of pop holes; and the superiority of foundation running 12 ft. to the pound over thinner kinds, since in the latter the bees show a tendency to cut holes.

Report of the department of entomology, V. H. LOWE and F. A. SIRRINE (*New York State Sta. Rpt. 1896, pp. 522-635, pls. 25*).—The report is divided into two parts; the first by V. H. Lowe, the second by F. A. Sirrime. After an introduction by the former, in which the principal lines of work are explained and the number of specimens in the station collection and the objects of the collection noted, the more important of various insects and their ravages are discussed.

Some of the more important injurious insects of the year (pp. 525-535).—Under this head there are noted the locusts (*Melanoplus femoratus*, *M. femur-rubrum*, and *M. atlantis*); striped cucumber beetles, the injuries of which have been of considerable importance in the western part of the State; asparagus beetles (*Crioceris asparagi* and *C. 12-punctatus*); aphids (*Myzus ribis* and *Rhopalosiphum ribis*), over 50 per cent of the former being noted as destroyed by parasites and spiders; red spider (*Tetranychus telarius*), which injuriously affected the raspberry bushes in Ulster County, New York, where they were shaded by trees, and also seriously injured currant bushes; chinch bug, (*Blissus leucopterus*), Putnam scale (*Aspidiotus ancylus*), and oyster-shell bark louse (*Mytilaspis pomorum*). The latter is not satisfactorily destroyed by kerosene emulsion unless the trunk is first well scraped and the emulsion applied in full strength with a stiff brush. Cankerworms were more abundant than during the previous year, mainly on account of remedial measures not being taken early enough nor continued with sufficient thoroughness.

Experiments with green arsenite (pp. 536-539).—Several experiments are noted with green arsenite or Sheele's green, which resulted in showing that the green arsenite will remain suspended in water for a longer time than Paris green, and hence can be applied more evenly to the foliage and requires less stirring in the tank, and that it will not

burn the foliage of potato vines when used without lime in the strength of 1 lb. to 150 gals. of water. Experiments show further, although the author does not conclude that Sheele's green is as effective as Paris green, that it has a very considerable insecticidal value. Experiments were made on basket willows, nursery stock, and potatoes, the solutions varying in strength from 1 lb. to 100 to 150 gal. of water.

Experiments with dendrolene (pp. 540-542).—Several experiments were made with this substance with the object of ascertaining whether trees are apt to be injured by its use and how it is to be used. It was applied to the trunks of trees in rings both high and above the ground and also at the base of the tree in both thick and thin layers. Where it came in contact with the soil it was found that it became granular, losing its sticky character to a large extent. When exposed to the weather a slight crust forms over it, which is not, however, sufficiently strong to permit the passage of insects as large as the female canker-worm moth. When applied to full-grown apple trees no injury resulted, but when applied during the growing season to the trunks of young bearing plum, cherry, or peach trees in such a way as to cover the entire trunk there is considerable danger of serious injury.

Combating the cottonwood leaf beetle (pp. 543, 544).—Experiments were made with green arsenite at the rate of 1 lb. to 150 gal. water, with and without the addition of lime, at the rate of 2 qt. to 45 gal., and with and without the addition of glue and of glucose. It was demonstrated that one of the most serious difficulties in the application of poisons to willows for this beetle lies in the fact that the mixture does not spread well on the willow leaf. Arsenite of lead did not adhere well, nor did an addition of glucose aid matters much. An addition of glue was more successful.

The pistol-case bearer (pp. 545-557, pls. 3).—A reprint of Bulletin 122 of the station (E. S. R., 9, p. 257).

A brief report of nursery stock inspection in western New York (p. 558).—Here it is noted that between 15,000 and 20,000 trees were inspected, about 3,000 of which were found infested with insects, mostly either by the peach-tree borer or the woolly aphid. Over 1,000 trees were rejected as worthless; the remainder were treated with insecticides. Each tree was carefully examined from the root to the top and only such as showed no evidence of insect work or disease were considered satisfactory. In addition to the insects noted there were found the oyster-shell bark louse, the scurfy bark louse, *Asterodiaspis quercicola*, and the pear-tree psylla.

The peach-tree borer (pp. 559-569, pls. 2).—An historical account of this insect (*Sannina exitiosa*), its distribution, the nature of its injury, its life history, and preventive and remedial measures, together with a partial bibliography.

The woolly louse of the apple (*Schizoneura lanigera*) (pp. 570-582, pls. 3).—The account given of this insect is similar in scope to the

last, but notes in addition the importance of the insect as a pest to nursery stock. The destruction of old apple trees is advised, as also the insecticides strong soap suds, kerosene emulsion, and hot water. Several pages are devoted to a bibliography.

Notes on the recent army worm outbreak (pp. 583-607, pls. 4).—A reprint of Bulletin 104 of the station (E. S. R., 8, p. 609), with the addition of an extended bibliography.

Miscellaneous notes of the season (pp. 608-619).—In this, the beginning of part second, the author notes briefly that experiments on cucumbers indicate that they can not be protected from attacks of the striped cucumber beetles by the use of either poisoned Bordeaux mixture or even poisoned resin-lime mixture; that the Colorado potato beetle will not feed on potato vines that have been thoroughly treated with Bordeaux mixture, and that the vines are also probably free from attacks of the flea beetle; that the squash borer can probably be entirely controlled by the cultural methods of harrowing the ground in the fall where the squash vines rest and uniform spring or even fall plowing to a depth of 6 or 8 in. and not reploting; that onion thrips may be controlled by planting a few rows of set onions on the margins of fields and spraying these every week or 10 days with kerosene emulsion, and that the red spider may be treated by gathering in the fall the leaves affected by it and burning them, and by spraying in the spring with a solution of whale-oil soap or with kerosene emulsion. The various experiments are given more or less in detail.

The pear midge (*Diplosis pyrivora*) is also discussed. Experiments were made with kainit, which was applied at the rate of 1,500 to 2,000 lbs. per acre. The author states that the experiments show that there is a decided gain in the use of kainit, but there is a question to be solved, namely, how long an orchard will stand an application of the fertilizer at the rates noted, especially where the orchard is on a tenacious clay soil; and he suggests the question whether plowing an orchard in midsummer will not be fully as discouraging to the midge as an application of potash salt. It is thought that the latter method is far preferable to the former. According to the observations made, the midges appear April 15 to 30, pair as soon as they rise from the ground, lay their eggs, and die within 24 hours.

Notes on the cabbage plusia and remedies for the same (pp. 620-628).—In summarizing the experiments in regard to this insect (*Plusia brassicae*), which are given more or less in detail, it is noted that the most practicable way of checking its work on lettuce is to keep the ventilators of forcing houses closed by means of mosquito netting. Where the insect affects cabbage in the open field poisoned resin-lime mixture or poisoned Bordeaux mixture to which resin mixture has been added may be employed. The resin-lime mixture was found to make Paris green and London purple adhere not only to the upper, but also to the lower, sides of the leaves.

Notes on remedies for cutworms (pp. 628-635).—Cutworms are discussed in their relation to the onion crop. The treatment found effectual was dried bran or middlings mixed with Paris green at the rate of 1 lb. of the latter to 50 of bran or 30 of middlings. Experiments were also made with Paris green added to resin-lime mixture, used as a spray. It was found to be more or less ineffectual. Relative to the amount of damage done, the highest noted is 99 per cent. The life history and habits are briefly touched upon and the belief expressed that the eggs of the insects are deposited later in the fall than is generally supposed, and that they do not hatch until the following spring.

Entomological section, H. OSBORN and E. D. BALL (*Iowa Sta. Rpt. 1896-97, pp. 112-125, pls. 5*).—The author briefly notes that the army worm did not occur in injurious numbers during 1897, an outbreak of the Hessian fly in the northwestern part of the State, plums as being in some cases seriously affected with plant lice, and the appearance of the San José scale in the State, and considers the life histories of leaf hoppers the principal subject of investigation during the year. The three species noted as affecting garden crops are *Agallia punctata*, *A. novella*, and *A. sanguinolenta*. Referring to the genus generally, the author states that—

“The species are very difficult of separation and little has been published in regard to their food habits or life histories. During the past season the three following species have been under observation and their larvæ and the general facts of their life histories determined. In order to correctly determine the species under observation, as well as those sent in from other States for determination, a systematic study of the genus was undertaken, the complete results of which will be published elsewhere. The genus was found to be separable into three groups, of which the three species treated are typical illustrations as far as structural characteristics of the adults are concerned, and the known facts in regard to the larvæ and life histories of the other species indicate that they, too, will be found to be very similar within the groups. In general, the species were found to be widely and generally distributed and subject to little variation except in depth of color. The three species treated, though by no means limited to that area, are all that are now known to occur in the northern and eastern part of the United States, while in the Southern States *constricta* replaces *A. punctata* and extends along the Atlantic coast to New York, but it is in the Southwestern States and down into Central America that the majority of the species occur. The species are all single brooded, in northern latitudes at least, and the larvæ agree in feeding on stems near the ground and hiding under rubbish.”

The first species, *A. punctata*, appears to be naturally an inhabitant of shady woods, feeding upon various species of Compositæ, Cruciferae, Chenipodiaceæ, etc. Its taste for horse-radish, cabbage, spinach, and sugar beets gives it economic importance. The remedy recommended is kerosene emulsion spray.

The second species is merely described. The third is noted as preferring open sunny localities and occurring in great abundance in most all places except damp and shady woods. Clovers, especially white clover, a large number of weeds, and sugar beets are objects of its attacks.

The species noted as affecting orchard and shade trees are *Macropsis apicatis*, *Bythoscopus distinctus*, *Pediopsis tristis*, *P. trimaculata*, *P. viridis*, *P. ferruginoides*, *Idiocerus alternatus*, *I. brunneus*, *I. monolifera*, *I. verticis*, *I. suovi*, *I. maculipeunis*, *I. prorancheri*, and *I. cratagi*. The first (*M. apicatis*), the author states—

“May be so plentiful as to give a rough appearance to the bark in places, and, while not apparently producing distortion of the twigs, probably because they are placed so close to the surface as not to affect the growing tissue, the fact that many of the twigs affected are deadened at the tip would indicate possible injury in this manner. The eggs occur mainly on the under surface of the twig, but whether this position is to give the egg more uniform conditions by protecting it from direct sunlight or to the avoidance of strong light by the adult, or some other reason, is a matter of conjecture. The deposition of the summer eggs has not been observed, but it doubtless coincides with that for the winter brood.

“The larvæ are stout and short, similar in color and shape to the adult, but entirely covered with coarse bristle-like hairs, rendering it easily recognizable. Larvæ and adults were found in abundance on the new growth at the end of the twigs of honey locust toward the end of June, occurring in hundreds on a single tree, and although isolated trees, trees in hedgerows, and those in the native timber were examined, as well as others in different parts of the State, none were found entirely free from this insect. The larvæ had all issued by the last of the month.”

The second (*B. distinctus*) occurs on black walnut, butternut, and on hickory and hackberry where they are adjacent to the first-mentioned tree. Full-grown larvæ are found during the second week in June and a second brood appears before the middle of August.

The species of *Pediopsis* are only briefly noted, but they all agree in being tree feeders, both as larvæ and as adults. *P. tristis* appears to be confined to plum trees and is often accompanied by *P. trimaculata*, which often exceeds the former in numbers. The most common species is *P. viridis* affecting most all the willows. The remaining species, *P. ferruginoides*, attacks the narrow-leaved willows,

Monograph of the Phymatidæ, A. HANDLIRSCH (*Ann. K. K. Naturh. Hofmus., Wien, 12 (1897), pp. 127-230, pls. 6, figs. 35*).—The work is divided into 3 parts. The first part deals with the questions of literature, morphology, anatomy, embryonic development, life history, geographical distribution, as well as the systemic position and relationships of the family. The Phymatidæ, especially considered as approaching the Aradidæ and Tingitidæ, the author, for morphological reasons, places in the neighborhood of the Reduviidæ. Their closest relatives are thought to be the Stenopodiniæ genera, Phimophorus and Aulacogenia.

The family is distributed over the palearctic, oriental, and neotropical regions. Some three-fourths of the known species belong to the New World. None are found to occur in Australia, Africa, or Madagascar. The 2 species of Phyneata described by J. Scott as from New Zealand are thought very uncertain.

The second part of the work is entirely systematic. Nine genera and 73 species are recognized, and of these 3 genera and 29 species are new. Three natural groups are recognized: Phymatiniæ with 1, Macrocephalinaæ with 6, and Carcinocoriniæ with 2 genera. The 3 new genera, Cnizocoris, Glossopelta, and Agrenocoris, belong to the second group.

Report of the professor of biology and geology, J. H. PANTON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 11-24, figs. 15*).—This notes briefly some 13 injurious insects and new fungi, with brief popular statements in each case as to proper

remedy. A somewhat lengthy note on the pernicious scale, which has appeared in the Province, besides mentioning something of the marvelous reproductive powers of this insect in the United States; notes on 3 classes of remedies applied to it, namely, corrosive washes, such as whale-oil soap, penetrating substances, such as kerosene emulsion and gases, and varnishes, such as resin washes. There are also given brief instructions as to spraying mixtures, note being made of Bordeaux mixture, ammoniacal copper sulphate, Paris green, 1 lb. to 200 to 300 gal., hellebore, pyrethrum, and kerosene emulsion.

Entomology, W. D. HUNTER (*Nebraska Sta. Rpt. 1897*, pp. 27-30).—The author briefly notes experiments with *Sporotrichum globuliferum*, *Empusa grylli*, and a bacterial disease of grasshoppers, commenting more or less favorably upon the effects of the first two and on insecticides. The latter were with carbon bisulphid, concerning which it is thought that the different conditions under which it may be effectively employed are not well known, and the experiments were undertaken to learn new methods of applying it, whereby the expense attending its use might be lessened. The substance was used against plant lice inhabiting cucurbitous plants, borers in peach trees, larvæ of May beetles in nurseries and young orchards, and some species, such as *Sitodrepa panicea*, which damage stored dry animal and vegetable matter.

Insect notes of the season, W. E. BRITTON (*Connecticut State Sta. Rpt. 1897*, pp. 314-319).—Descriptive and life history notes are given on the following insects, with an account of their injuries during the season and suggestions as to remedies: Apple curculio (*Anthonomus quadrigibbus*) on peach twigs; San José scale; "virgin" or "white ermine" moth (*Spilosoma virginica*) on hollyhocks; grapevine flea-beetle (*Haltica (Graptoderu) chalybea*); a plant louse (*Pemphigus acerifolii*) on maples; a lily-stalk borer, closely resembling *Gortyna nitela*, and presumably that species; saw-tooth grain beetle (*Sitranus surinamensis*); meal snout moth (*Pyralis farinalis*), and plant lice. A technical description is given of the lily-stalk borer. The gypsy moth (*Oenaria dispar*) was reported from Hartford, but as all the specimens were destroyed the scientific accuracy of the report could not be determined. The author is inclined to believe, however, that the larvæ belonged to some of the more common species and not to the moth imported from Europe.

Some new spiders, N. BANKS (*Canad. Ent., 30 (1898), No. 7, pp. 185-188*).—*Pacilochroa minuta* from Brazos County, Texas; *Cybæodes (?) incerta* from Salton, California; *Theridium subterraneum* from Washington, D. C.; *Nasticus caricola* from Chiricahua Mountains, Arizona; *Erigone albescens* from Washington, D. C.; and *Philodromus pacificus* from Olympia, Washington.

The contests against grasshoppers in the delta of the Danube, E. REKALO (*Selsk. Khoz. i Lyesor., 187 (1897), Oct., pp. 99-126*).—Since the chief brooding ground of the grasshoppers devastating Bessarabia is at the delta of the Danube, the author recommends joint action of Russia and Roumania in combating the insects at the delta.—P. FIREMAN.

Insects injurious to Helianthus annuus, A. KRULIKOVSKI (*Selsk. Khoz. i Lyesor., 185 (1897), June, pp. 585-598*).

The San José scale (*Pennsylvania Dept. Agr. Bul. 34, pp. 45-49*).—A popular paper, quoting largely from P. H. Rolt (*E. S. R., 9, p. 1068*), from J. P. Smith and F. M. Webster.

Bordeaux mixture as an insecticide, J. H. PANTON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, p. 24*).—Experiments were made with Bordeaux mixture on gooseberry bushes to test its efficacy as an insecticide. Three applications were given the bushes. Further experiments were conducted in spraying tent caterpillars with Bordeaux mixture and Bordeaux mixture with Paris green. The Bordeaux mixture seemed to have some effect as an insecticide, but the author believes that applications of limewater gave results similar to those of Bordeaux mixture. The addition of Paris green increased the efficiency of the mixture.

FOODS—ANIMAL PRODUCTION.

The composition of hay as affected by maturity, R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 31-38*).—During the seasons of 1896 and 1897 clover and timothy were cut at different stages of maturity, and during the last year alfalfa also. The clover was cut when the first blossom was just appearing, when a third of the blossoms had turned brown, and when the heads had all turned brown or were dead; the alfalfa when the plants began to bloom, when they were in full bloom, and when most of the blossoms had fallen, and the timothy when the heads began to appear, when the first blossoms had just fallen, and when the seeds were well formed.

Analyses are given of the different cuttings, together with the calculated yield of dry matter. A digestion experiment with one sheep was made with each cutting, and from the results the yield of digestible dry matter is calculated.

The results indicated that in each case the crop deteriorated and its digestibility decreased with maturity and that alfalfa contained the largest amount of digestible matter from early to full bloom. It is recommended that clover be cut when the heads begin to turn brown and timothy soon after the first blossoms fall. When alfalfa has reached its full bloom it deteriorates faster than clover or timothy.

Food value of California eggs, M. E. JAFFA (*California Sta. Rpt. 1895-1897, pp. 120-121*).—A comparison which included the physical properties and composition was made of brown-shelled and white-shelled hens' eggs. The brown-shelled eggs were from Partridge Cochins, Dark Brahmas, Black Langshaus, Wyandottes, and Barred Plymouth Rocks; and the white-shelled from Brown Leghorns, Buff Leghorns, White Minorcas and Black Minorcas. The size, weight, specific gravity, and the ratio to total weight of the shell, yolk, and white are shown in the following table:

Comparison of brown-shelled and white-shelled eggs.

	Weight.	Length.	Width.	Specific gravity.	Number of eggs to lb.	Shell.	Edible portion.		
							Total.	Yolk.	White.
	<i>Grams.</i>	<i>Inches.</i>	<i>Inches.</i>			<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Brown shelled eggs (average of 6 breeds)	59.4	2.27	1.69	1.082	7.67	10.70	89.30	31.76	57.54
White-shelled eggs (average of 4 breeds)	62.9	2.27	1.76	1.058	7.33	10.92	89.08	33.18	55.90
Average of above ...	61.3	2.27	1.72	1.070	7.50	10.81	89.19	32.47	56.72

The composition of the eggs of the different breeds is recorded in detail. The averages are given in the following table:

Analyses of brown-shelled and white-shelled eggs.

	Water.	Protein.	Fat.	Ash.	Shell.	Total.	Fuel value per pound.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Calories.</i>
Brown-shelled eggs:							
Yolk	49.59	15.58	33.52	1.04	99.73	1,712
White	86.60	11.99	.21	.54	99.34	224
Entire egg	65.57	11.84	10.77	.64	10.70	99.52	670
White-shelled eggs:							
Yolk	49.81	15.49	33.34	1.05	99.69	1,696
White	86.37	12.11	.35	.56	99.32	240
Entire egg	64.79	11.92	11.22	.67	10.92	99.52	690

"It has been said by some that the brown eggs are richer than the white ones. This statement is not borne out by a chemical analysis, and the physical examination proves that the main points of superiority, although extremely slight, are possessed by the white eggs. The minute differences that are found between the two groups are exceeded by variation between the varieties within the same group.

"We can therefore state as a conclusion, both from a chemical and a physical point of view, that there are practically no differences, so far as the food value is concerned, between the white-shelled and brown-shelled eggs."

Report of the chemical department, H. A. HUSTON (*Indiana Sta. Rpt. 1897, pp. 16-24*).—Brief statements are made concerning the work of the station on sugar beets, fertilizer experiments on clay soils, experiments on the prevention of root rot, and laboratory studies on available plant food in worn soils. Many samples of cheese purchased in the open market were examined, but no filled cheese was found. "The cheap cheese that has taken the place of the filled cheese contains very little fat and the casein [when tested by methods of artificial digestion] seems to be in such a condition as to offer great resistance to digestive ferments." Analyses are reported of linseed meal, cotton-seed meal, silage from corn stover, purslane, rye middlings, buckwheat middlings, Idaho coffee pea, malt sprouts, wheat, strawboard waste (fertilizing constituents), and marl.

The analyses of purslane, Idaho coffee pea, and strawboard waste are given in the following table:

Composition of purslane, Idaho coffee pea, and strawboard waste.

	Water.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.	Total nitrogen.	Phosphoric acid.	Potash.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Purslane (<i>Portulaca oleracea</i>)	86.56	1.81	0.50	6.49	2.12	2.23	0.29	0.045	0.85
Idaho coffee pea	6.75	15.37	6.56	65.53	2.47	3.28	2.46
Strawboard waste	69.6732	.21	.14

The purslane contained 0.23 per cent albuminoid nitrogen and 0.06 per cent amid nitrogen, and the Idaho coffee pea 2.32 per cent and 0.14 per cent of these constituents.

"The purslane compares favorably with average samples of corn fodder so far as the protein and ether extract are concerned. Nitrogen-free extract is rather lower than in most green fodder, but the amount of water is considerably higher. The ash is higher than any ash that I have seen reported in green feeding stuffs. Owing to the relatively low amounts of fiber and nitrogen-free extract, the nutritive ratio is high, being about 5.5. The material has been used to some extent in this State for many years as a food for pigs, and in many localities is highly esteemed. Analysis shows that it is well worth consideration as a feeding material for such animals as will eat it readily.

"The material has also a relatively high fertilizing value."

Brief statements concerning other analytical work are also made.

Investigation of California cattle foods, M. E. JAFFA (*California Sta. Rpt., 1895-1897, pp. 112-116*).—Analyses are reported of mixed feed, shorts, middlings, wheat bran, rice bran, linseed-oil cake, cocoanut-oil cake, bur clover, clover (*Trifolium wormskioldii*), malt sprouts, sugar-beet pulp, Egyptian corn, silage from sugar beet pulp, barley, clover, corn, and sugar beets. In every case the digestible matter in 100 lbs. was calculated.

The composition of a number of these feeding stuffs is shown in the following table:

Composition of California cattle foods.

	Water.		Protein.		Fat.		Nitro- gen-free extract.		Crude fiber.		Ash.		Fuel value.		Nutri- tive ratio.	
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Calories.</i>	<i>Per ct.</i>

a Average of Common White, Red, and Jerusalem.

Analyses of feeds, A. L. WINTON, A. W. OGDEN, and W. L. MITCHELL (*Connecticut State Sta. Rpt. 1897, pp. 319-321*).—Analyses are reported of chaff, oat feed, "Oatena," corn and oats, corn meal, corn-meal germ, gluten feed, mixed feed, and hay of the flat pea (*Lathyrus sylvestris*). The percentage composition of the "Oatena" was as follows: Water, 7.12; protein, 8.75; fat, 4.03; nitrogen-free extract, 59.16; fiber, 16.19, and ash, 4.75. The composition of *Lathyrus sylvestris* hay was as follows: Water, 10.25; protein, 26.84; fat, 3.81; nitrogen-free extract, 28.27; fiber, 26.51, and ash, 4.32.

The method of establishing a meadow of flat peas by seeding and transplanting is described. This season about one-fourth of an acre,

grown in part from seed sown in 1895 and in part from plants transplanted in 1896, yielded nearly a ton of hay from two cuttings.

Different quantities of meal for fattening steers, E. G. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 81-83*).—A test was made with one lot of 3 and two lots of 2 steers of medium quality to compare light and heavy grain rations. After a preliminary period of 3 weeks the experiment proper covered 216 days, ending July 8, 1897. The lots were fed at first all the straw they would eat morning and evening, with 10 lbs. of hay at noon, and later all the hay they would eat. They were also given at noon 20 to 25 lbs. of turnips. During the latter part of the test, however, 14 to 20 lbs. of silage was substituted for turnips. All the steers were fed grain consisting of equal parts by weight of peas, barley, and oats, the plan being to increase the amount fed until lot 1 was given 1 lb. per day for every 100 lbs. live weight, lot 2 $2\frac{2}{3}$ lb., and lot 3 $3\frac{1}{3}$ lb. Before the close of the test lot 1 consumed 12 lbs. of grain per day. The heavy grain ration was consumed in three portions and the light ration in two portions.

The financial statement is based on meal at \$13, hay at \$6, straw at \$3, silage at \$2, and roots at \$2 per ton.

The results of the test are shown in the following table:

Results of feeding heavy and light grain rations to steers.

	Average weight at beginning.	Average gain per day.	Net profit per steer.
	Pounds.	Pounds.	
Lot 1 (heavy ration).....	900	1.80	\$9.62
Lot 2 (medium ration).....	1,000	1.77	14.50
Lot 3 (light ration).....	988	1.56	13.64

“The heavy-ration steers made the greatest gain, but gave the smallest profit, the largest profit being obtained from the medium-ration steers.”

The steers were sold and the meat judged by an expert. Definite conclusions are not drawn.

Comparison of sweet and sour whey for pigs, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 85-88*).—In continuation of previous work (E. S. R., 9, p. 487) three experiments were made to test the comparative value of sweet and sour whey for fattening pigs. The first test was made with three lots of 3 pigs each. During the preliminary period all the pigs were fed the same amount of sweet whey and grain. The quantity of whey was at first small and was gradually increased. During the experiment proper sour whey was substituted for sweet whey in the ration of lot 2 and water for whey in the ration of lot 3. The pigs were given all they would eat. The whey and grain were fed in the proportion of 2:1. The grain consisted of equal parts by weight of barley, peas, and shorts.

At the beginning of the test the three lots weighed 374, 377, and 377

lbs., respectively. During the preliminary period of 7 days the average daily gain per pig for the three lots was 1.24, 1.29, and 1.52 lbs. During the experiment proper (29 days) the average daily gain per pig for the three lots was 1.38, 1.26, and 1.35 lbs. Lot 1 consumed 3.36 lbs. of grain and 6.17 lbs. of whey per pound of gain; lot 2, 3.70 lbs. of grain and 6.79 lbs. of whey; and lot 3, 4.28 lbs. of grain per pound of gain.

The second test was begun with three lots of 3 pigs under the same conditions as the first. However, it was necessary to drop lot 1 before the close of the test. Lot 2 (fed sour whey and grain) weighed 230 lbs. at the beginning of the test and made an average daily gain per head of 1.26 lbs. during the preliminary period of 14 days. Lot 3 (fed grain and water) weighed 227 lbs. at the beginning and during the 14 days made an average daily gain of 1.31 lbs. During the experiment proper, which continued 64 days, lot 2 made an average daily gain of 1.36 lbs., consuming 3.48 lbs. of grain and 6.96 lbs. of whey per pound of gain. During the same period lot 3 made a daily average gain of 1.41 lbs. and consumed 4.18 lbs. of grain per pound of gain.

The third test was made with the same number of pigs and under the same conditions as the first. The three lots weighed 290, 295, and 289 lbs. and during the preliminary period of 10 days made an average daily gain of 1.76, 1.50, and 1.70 lbs. During the experiment proper, which covered 31 days, lot 1 made an average daily gain of 1.87 lbs., consuming 3.54 lbs. of grain and 6.09 lbs. of whey per pound of gain. The corresponding figures for lot 2 are 1.96 lbs. gain and 3.37 lbs. grain and 5.79 lbs. whey; and for lot 3, 2.07 lbs. gain and 3.91 lbs. grain per pound of gain.

The pigs were sold and the meat judged by an expert. No bad effects attended the use of whey. Somewhat better gains were made on sour whey than on sweet whey.

Comparison of different breeds of swine, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 88-90*).—In continuation of work previously reported (*E. S. R.*, 9, p. 478) a test was made with 6 lots of 6 pigs each to compare the following breeds: Improved Yorkshire, Chester-White, Duroc-Jersey, Tamworth, Poland-China, and Berkshire. But one breed was represented in each lot. A record was kept of the food consumed and the gains made by the different lots between the ages of 90 and 180 days. All the pigs were fed grain of some sort, but detailed statements as to the feeding stuffs used and the methods of feeding are not given.

The gains made during 90 days and the food consumed per pound of gain for the different breeds are shown below :

Results of feeding pigs of different breeds.

Breed.	Average weight at beginning.	Average daily gain per pig.	Grain consumed per pound of gain.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Berkshire	53.00	1.02	3.27
Tamworth	52.00	.97	3.31
Poland-China	52.33	.84	3.33
Chester-White	51.66	.83	3.40
Yorkshire	60.33	.93	3.41
Duroc-Jersey	64.66	.94	3.58

The breeds are arranged in the table in the order of economy of gain, but in the author's opinion the experimental data are not sufficient for general conclusions. The pigs were slaughtered and the flesh of representatives of each breed judged by an expert as regards its suitability for export bacon. General deductions on this point are not drawn.

Feeding trials with crossbred swine, W. P. WHEELER (*New York State Sta. Rpt. 1896, pp. 658-665*).—A tabular record is given of feeding five lots of crossbred pigs from birth until time of marketing, when 7 months old. The sow was fed with each lot until the pigs were 8 weeks old. The several lots were given like rations at similar stages of growth. For the first 4 weeks, wheat bran was fed with skim milk, which latter always formed part of every ration. During the second period of 4 weeks, a mixture of equal parts of wheat bran and wheat middlings was fed. Other grain mixtures, containing corn meal in increasing proportions, followed.

Rating wheat bran at \$18 per ton, corn-meal middlings at \$20 per ton, and skim milk at 25 cts. per hundred pounds, the cost of the gain in weight of the different crosses during the 28 weeks was as follows: Tamworth-Duroc cross, 3.83 cts. per pound; Yorkshire-Tamworth, 3.25 cts.; Tamworth-Poland China, 3.44 cts.; Ohio Improved Chester-Poland China, 3.61 cts.

After the pigs were removed from the sows, the cost of food per pound of gain for the different lots was: Tamworth-Yorkshire cross, 2.48 cts.; Tamworth-Duroc, 2.41 cts.; Yorkshire-Tamworth, 2.17 cts.; Tamworth-Poland China, 2.33 cts.; and Ohio Improved Chester-Poland China, 2.37 cts. "It will be seen from these figures that there was little difference in the efficiency with which each lot utilized the food."

A considerable difference was observable in the rapidity of growth of the different crosses. The Tamworth-Poland China pigs at the end of the test averaged 262 lbs. each. This was 11 per cent heavier than the average of the Yorkshire-Tamworth cross, the lot nearest them in size, and over 36 per cent heavier than the Ohio Improved Chester-Poland China cross.

The fecundity of swine, A. W. BITTING (*Indiana Sta. Rpt. 1897, pp. 12-16*).—According to the author the impression is prevalent that pure-bred swine are unprofitable for breeding purposes, as it is thought that as the breed is improved fecundity decreases. The author compiled the number of pigs farrowed and raised in the first and last 200 litters recorded in registers of Berkshire, Poland-China, and Chester White pigs. These are quoted in detail. The popular opinion is not confirmed by this investigation.

“While there seems to be a reduction in the number of very large litters, the total number farrowed is about the same as shown by the first records.

“It is not the intent to compare breeds, but to compare the earliest and latest records of litters to determine whether there has been a real gain or loss in the fecundity of the breed.

“The number of boars and sows raised was as follows: Berkshire, 400 litters, 2,866 pigs, 1,498 boars, 1,368 sows; Poland-China, 1,000 litters, 6,542 pigs, 3,228 boars, 3,314 sows; Chester White, 600 litters, 4,555 pigs, 2,236 boars, 2,319 sows. In a total of 3,693 pigs farrowed and all raised, there were 1,786 boars and 1,907 sows.”

Report of the poultry manager, L. G. JARVIS (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 223-231, figs. 11*).—General statements are made concerning the diseases and animal parasites of poultry, testing of eggs, development of chickens, etc. The value of different foods is discussed, and several different winter rations are suggested. The protein, phosphoric acid, and calcium oxid in fresh green bone, meat meal, and dried-blood meal were determined.

A test was made of the keeping quality of fertile and infertile eggs. Four dozen fertile and three dozen infertile eggs were placed in an egg closet the middle of July, 1897, and kept at a temperature of 50 to 60°. The eggs were laid on the sides in bran and were not turned. At the end of a month no perceptible difference was observed in the two kinds of eggs. This was also the case the middle of September. A month later it was observed that the whites of the fertile eggs were more watery than those of the infertile eggs. No difference was observed, however, in the yolks. At the conclusion of the test (the middle of November) the whites of the fertile eggs were watery and in some cases the yolks were broken. When this was not the case, they were much spotted and discolored and the eggs totally unfit for table use. The infertile eggs were in good condition. The whites and yolks had a normal appearance and no tendency toward decay was observed. In the author's opinion the eggs were of as good quality as the average commercial product, though inferior to new-laid eggs. Experiments along this line will be continued.

Brief notes are given on crossbreeding tests made during the season. The information which was furnished in reply to requests received during the year is quoted.

Second report on food products (*Connecticut State Sta. Rpt. 1897, pp. 1-64*).—This contains the text of the Connecticut food law of 1895, and reports on the examination of food products in accordance with the provisions of the law. Samples of the fol-

lowing foods and condiments were analyzed during the past year: Black, white, and cayenne pepper, allspice, cinnamon, cloves, coffee, date-stone coffee, catsup, Chile sauce, honey, maple sirup, confectionery, sausage, mince-meat, head cheese, codfish, olive oil, oysters, milk, vinegar, molasses, sirup, cream, butter, and imitation butter. Of the samples examined 695 were not adulterated, 209 were adulterated, and 93 contained borax, salicylic acid, or benzoic acid.

Human food, J. KÖNIG (*L'alimentation humaine*. Paris, 1898).—Tables showing the composition of human foods, translated by X. Rocques.

List of publications of the Office of Experiment Stations on the food and nutrition of man (*U. S. Dept. Agr., Office of Experiment Stations Doc. 238 (rev.)*, pp. 4).

Qualitative and quantitative determination of wheat flour in rye flour, S. WEINWURM (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 1898, No. 2, pp. 98-101).

Sugar as a feeding stuff for animals in the region about Paris, J. BRUHAT (*Jour. Hyg.*, 23 (1898), No. 1132, pp. 253-256).—A general article pointing out the value of sugar and molasses as feeding stuffs. Many references are made to recent work on the subject.

Concentrated feeding stuffs for sheep, N. DYUMIN (*Selsk. Khoz. i Lyesov.*, 184 (1897), No. 3, pp. 672-683).—Tests were made to determine the feeding value of cotton-seed hulls, corn, and bran, with hay and straw, using 80 sheep divided into 8 equal lots. The test lasted from December 23 until April 4. The gains in weight were recorded. On this basis the best results were obtained with a ration of corn and wheat straw, followed by corn and hay, bran and hay, cotton-seed hulls and hay, bran and straw, hay alone, cotton-seed hulls and straw, and straw, in the order mentioned.—P. FIREMAN.

The utilization of cocoa shells, G. PARIS (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 1898, No. 6, pp. 389, 390).—The composition of cocoa shells and a decoction made from them is reported.

Do coffeon and caffen-free coffee surrogates produce the effect of coffee? K. B. LEHMANN and F. WILHELM (*Arch. Hyg.*, 23 (1898), No. 4, pp. 310-326).—Coffeeon is a product obtained by condensing the material volatilized when coffee is roasted. Experiments were made with man with coffee, caffen, coffeon, coffee distillate, an ether extract of coffee, coffee surrogates, fig coffee, and chicory. The principal conclusions follow: The pleasant flavor of coffee is due to coffeon. None of the toxic effects which follow large doses of coffee could be attributed to this. Neither fig coffee nor chicory produced any effect.

Do the volatile aromatic constituents of tea (tea oil) produce a noticeable effect on man? K. B. LEHMANN and B. TENDLAU (*Arch. Hyg.*, 23 (1898), No. 4, pp. 327-352, *djms.* 3).—Experiments were made with man on the effect of the volatile extract of tea obtained by distillation with steam and the material obtained by extraction with water or by extracting the dry tea with ether. In the authors' opinion the flavor of tea is due to the oil, i. e., volatile material, but it has scarcely any other effect.

The energy expended in bicycle riding, SEHRWALD (*Arch. Hyg.*, 23 (1898), No. 4, pp. 353-410, *tables* 2).—An extended study of the energy expended in riding a bicycle under various conditions. A formula for calculating the energy from a number of factors which may be measured is given.

The chemical analysis of the gastric contents, H. E. HEWES (*Boston Med. and Surg. Jour.*, 1897, Nov. 25 and Dec. 2; reprinted in *Amer. Jour. Pharm.*, 70 (1898), Nos. 1, pp. 25-44; 2, pp. 94-109).—The author gives in detail the method of analysis of the products of gastric digestion, and reports analyses of the gastric contents of 50 healthy individuals. The article also contains general information on digestion and many references to the literature of the subject.

The poisonous action of urine, A. BECK (*Arch. Physiol. [Pflüger]*, 71, No. 11-12, pp. 560-595).

On mucus in human feces, A. SCHMIDT (*Ztschr. Klin. Med. [Berlin]* 32, pp. 260-279, *pl.* 1).—A somewhat extended study on the mucus in human feces. The subject is considered from a medical standpoint.

Live stock, W. RENNIE (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, pp. 217-220).—Brief statements are given concerning the feeding and care of steers, milch cows, sheep, swine, and horses at the Ontario Experimental Farm during 1896-97. The amount and cost of the foods consumed by 11 steers and the price received for them are recorded. Comparative tests of the different feeds were not made.

"The steers and milch cows are fed a full ration morning and night of silage, pulped roots, clover hay and chaff, and chopped grain and bran. At noon they get only 25 lbs. of sliced roots. Under this system better results are obtained, and the animals are healthier than with three full feeds per day."

The average weight of the fleece of the different breeds of sheep is recorded.

The cost of cattle raising in Argentine Republic (*Mitt. Deut. Landw. Gesell., 1898, Nos. 9, Sup., pp. 66-72; 10, Sup., pp. 73, 74*).

Feeding experiments with laying hens, W. P. WHEELER (*New York State Sta. Rpt. 1896*, pp. 666-687).—A reprint of Bulletin 106 of the station (E. S. R., 8, p. 819), with the addition of some detailed tabular data.

DAIRY FARMING—DAIRYING.

On the question of the processes of milk secretion, DISSELHORST (*Ztschr. Fleisch u. Milchhyg., 8, No. 8, pp. 146-150*).—This article is based upon investigations recently conducted by L. Michaelis in the laboratory of Prof. O. Hertwig in Berlin and published as an inaugural dissertation.

Michaelis reviews the literature of milk secretion and enumerates the following groups of questions which are still in doubt: (1) Is the constant change in the form of the separating epithelium of the glands dependent upon the activity of the secretion, or is it a mechanical result of the fullness of the alveolus? (2) Does a breaking down of the epithelial nuclei (which are always present in the first part of the secretion) take place; and, if this is the case, in what manner are these nuclei replaced? (3) What part do the leucocytes take in milk production? (4) Is the fat a product of the degenerated epithelial cells, or is it a secretion from these cells?

To answer these questions Michaelis made very comprehensive investigations on the milk glands of cows, guinea pigs, and mice in various stages of lactation. The lumen of the alveoli of pregnant animals contains immense leucocytes, which show amoeboid motion, and which often contain one or several drops of fat. These cells have only one nucleus and are, as will be seen later, of great importance in the formation of colostrum. The alveoli and the interstitial tissue also contain large numbers of polynuclear lymph corpuscles, which may also be

found between the individual epithelial cells. Eosinophil cells were likewise observed in large numbers.

An investigation of the contents of the mammary glands of pregnant guinea pigs for a period of 4 weeks showed an alternating occurrence of leucocytes and colostrum corpuscles; when both kinds were present all of the different transformation stages were observed. This gives rise to the question as to the origin of the colostrum corpuscles. Michaelis concludes that they consist of leucocytes, and especially of the mononuclear lymph corpuscles which have taken up fat globules. In no case do they result from a fatty degeneration of the leucocytes, as Rauber states, for in the first place they have a nucleus and in the second place they show amoeboid movements. This accounts for the mononuclear leucocytes, and the question arises as to the rôle of the leucocytes with several nuclei. Michaelis found that they break down after an active division of the nuclei has taken place.

The fate of a lymph corpuscle which penetrates the epithelium of the mammary glands is, therefore, (1) that either it increases in size, takes up fat globules, and becomes a colostrum corpuscle (always mononuclear), or (2) after enlarging slightly the nucleus breaks up and then the cell. As to the further fate of the colostrum bodies, Michaelis was not able to determine definitely: but the probability of their returning to the lymphatics, as suggested by Czerny, is excluded by their immensely increased size.

While the above refers to the condition of the mammary glands of pregnant animals before parturition, the glands of suckling animals present a totally different appearance. Here the interstitial connective tissue has been reduced to a minimum, the acidophile cells have disappeared, and also the lymphatic corpuscles in the connective tissue. There is hardly a leucocyte to be seen, but in their place clusters of free nuclei are observed in the secretion, which in all respects resemble the nuclei of the epithelial cells. Michaelis could plainly observe the expulsion of these nuclei, some of which still adhered to their cells. Other investigators have made similar observations, but the fact that karyokinesis had never been observed in the actively secreting gland made this one of the darkest points in the etiology of milk secretion. All are agreed, however, that the actively secreting glands contain a larger number of nuclei than the reverting ones. As to the origin of these nuclei, Michaelis was able to find polynuclear epithelial cells in which direct cell division was taking place. Indications of this appeared immediately after parturition, when nuclei of various sizes and shapes were to be seen. This had escaped previous observers. As a result of his discovery the statement is made that the innumerable nuclei which are present in the lumen of the milk ducts and alveoli are expelled by the epithelial cells, in which they are formed by direct karyokinesis. However, these nuclei do not occur in normal milk, as they are disintegrated through chromatolysis and form a homogenous mass of achro-

matic substances. In some cases this retrogressive change is apparent before the nucleus leaves the epithelial cell, although much the larger portion are intact when they reach the alveoli.

The form of the epithelial cells exhibits some very typical changes during lactation. According to Michaelis they are first cubical, then papilliform, then cubical again, and finally flat. It is quite possible that the albuminoids of milk are produced by these cells at certain stages of the secretion, when they protrude like papillæ into the lumen of the alveoli.

Until recently fat has been regarded as a result of a degeneration of the glandular epithelium. If this proposition were correct it would call for a double layer of epithelium in the secreting glands, while, as shown above, there is only one layer. Consequently the formation of fat in the mammary glands is not due to a degeneration of the glandular epithelium, as in the case of the sebaceous glands, but rather to an infiltration of fat which the epithelial cells extract from the circulating supply of blood and lymph. The epithelium secretes or separates the fat itself by extracting it out of the fluids (soaps) furnishing it, and no breaking down of the epithelium takes place.

Regarding the disputed question as to whether the fat globules are inclosed in a membrane, Michaelis concludes that they are not. Not the slightest trace of a membrane was found.

As milk sugar is not a morphological element of milk, it is considered impossible to determine its origin until further advancement has been made in micro-chemistry.

The casein, however, is evidently composed of albuminoid bodies secreted by the cells, and formed by disintegration of the nuclei. The latter process accounts for the nuclein content of milk shown by Heidenhain and Nissen.

Since, as shown above, only a few nuclei of the epithelial cells are broken down during the colostrum period, the chemical difference between milk and colostrum is explained; the milk contains more casein (including nuclein) and the colostrum more albumin.

Concerning the behavior of the mammary glands in the involution period, the most noticeable feature is the return to the production of colostrum. "The secretion of a guinea pig at the end of gestation can not be distinguished from that produced the day after the young have been weaned." The eosinophil cells appear again, leucocytes penetrate the epithelium in large quantities and break down in the alveoli or are transformed into colostrum bodies. This is true, no matter how long a time has elapsed since giving birth. The whole process of reformation of the glands takes place very soon after weaning; the alveoli materially diminish in size, and the interstitial connective tissue materially increases.

The results of investigations on this subject, especially those of Michaelis, are summarized by the author as follows:

(1) The epithelium of the mammary glands is composed of only one layer.

(2) The fat of milk is a true product of secretion—a product of the life activity of the cells and not a product of their degeneration.

(3) At the present time nothing definite can be said regarding the method of secretion of milk sugar.

(4) Casein is a compound product, derived partly from albuminoid bodies produced by the excreting epithelial cells, and partly from the disintegrated nuclei of these cells. The nuclein of milk is derived from the latter source.

(5) The fat globules are not inclosed in a membrane.

(6) The colostrum bodies originate from large, mononuclear leucocytes, capable of amœboid motion. These bodies reappear in the involution period of the glands. The leucocytes take no part in the production of milk, and the polynuclear ones disappear; but during gestation, immediately after birth, and for a short period after weaning, they pass through the epithelium in all forms and in great numbers.

(7) During lactation large quantities of free epithelial nuclei are found in the lumen of the alveoli, which decompose and assist in forming an integral constituent of the milk, namely, the casein.

(8) The pressure of the secretion in the alveoli may flatten the cubical cells, but at certain stages the cells of the mammary glands are papilliform. The latter condition is not due to the stage of fullness of the lumen, but indicates an independent change of form in the epithelium during lactation.

Analyses of milk, A. L. WINTON, A. W. OGDEN, and W. L. MITCHELL (*Connecticut State Sta. Rpt. 1897, pp. 321, 322*).—Analyses are reported of the mixed milk of 6 cows on the last day of each of 4 periods of 2 weeks' duration on different feeds. The feeding was not done at the station, but the samples were sent for analysis. In the first and third periods the cows were fed cut-corn fodder, hay and corn silage with a mixture of wheat bran and cotton-seed meal, 1:1. In the second and fourth periods the coarse fodder remained the same, but wheat bran and Cleveland linseed meal 1:1 were substituted for bran and cotton-seed meal in the proportion of 3 qt. to 2. During the linseed-meal periods the milk contained somewhat less fat and more water than during the other periods. No data are given as to the yield of milk.

Analyses of some California creamery butters, M. E. JAFFA (*California Sta. Rpt. 1895-1897, pp. 116-120*).—In order to compare California butter with premium butter from the American Dairy Show at Chicago, analyses were made of 6 samples of creamery butter from the bay region and 6 from Humboldt County. In addition, samples of

French and Danish butter were analyzed. The average results are shown in the following table:

Composition of butters.

	Water.	Fat.	Curd.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
California butter:				
Bay region (average of 6 samples)	10.55	85.05	1.44	2.99
Humboldt County (average of 6 samples)	11.42	84.15	1.06	3.37
Foreign butter:				
Danish	6.95	90.35	1.08	2.52
French	10.55	82.95	1.10	5.40

"We can safely say that as regards chemical composition the California butters are the equal in all respects of the Eastern product. . . .

"The sample of Danish butter analyzed could not have been a representative one, owing to the abnormally low percentage of water and high percentage of fat shown in the analysis."

The American and English methods of scoring butter are discussed.

Test of milk for tubercle bacilli, STORCH (*Milch Ztg.*, 27 (1898), No. 30, p. 472).—To a spoonful of milk in a test tube a few drops of hydrogen peroxid are added and then a few drops of paraffinglendingiaming ($C_6H_4(NH_2)_2$). If the milk is free from tubercle bacilli there is no change in color, but if bacilli are present the milk is said to change immediately to a grayish green color on shaking.

Experiments in butter making, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, pp. 59-68).—*Feeding silage to cows* (pp. 59-62).—In this experiment, lasting from May 6 to 26, the cows were divided into two lots of 10 each, one lot receiving 50 or 60 lbs. of silage per day with some uncut hay, and the other lot receiving 35 lbs. of silage with 10 or 12 lbs. of cut-clover hay and about $\frac{1}{3}$ bu. of mangel-wurzels. In addition both lots received 8 lbs. of mixed grain, consisting of equal parts of bran, peas, oats, and linseed meal. In all 13 different churnings were made. The cream from the silage lot was churned at a temperature ranging from 55 to 61° and averaging 57°, and that from the mixed feed lot from 54 to 61° and averaging 57°. The former churned on an average in 33½ minutes, while the latter required 42 minutes. The butter was scored when about a month old, and again when over 2 months old, with the following results:

Scoring of butter made on silage and on mixed feed.

	Silage butter.			Mixed-feed butter.		
	Flavor. (Max. 45.)	Grain. (Max. 25.)	Total score. (Max. 100.)	Flavor. (Max. 45.)	Grain. (Max. 25.)	Total score. (Max. 100.)
First scoring	39.0	23.4	91.3	39.8	23.4	92.0
Last scoring	35.6	23.0	87.0	36.8	23.0	88.2
Average	37.7	22.2	89.7	38.6	23.2	90.4

“(1) The cream from silage feed churned more easily than that from mixed feed.

“(2) The highest score for flavor was 12 points out of a possible 45. Two lots of silage butter scored 42, and three lots of the other scored this number. In grain, 24 points was the highest score obtained from a possible 25. The silage butter scored 21 six times, and the mixed-feed butter 24 five times. According to the judgment of the expert, the flavor of the butter was slightly better from the mixed feed (0.8 of a point in the average of 13 trials), and it also held its flavor slightly better. The mixed-feed butter lost 2 points by keeping one month in an ordinary cool room, while the silage butter lost 3.4 points in flavor by keeping.

“We can recommend good corn silage for feeding cows to produce milk for butter-making, but would prefer having it mixed with other foods, rather than feeding it in large quantities by itself.”

Effect on milk and butter of feeding turnips to cows (pp. 62-64).—In an experiment commenced in February, 1897, 6 cows were divided into three lots. Lot 1 was fed turnips just before milking, lot 2 was fed turnips after milking, and lot 3 received no turnips but was confined and milked in a stable in which the odor of turnips fed to fattening steers was very strong. During the first week lots 1 and 2 were fed 1 peck of turnips per cow daily and during the second week $\frac{1}{2}$ bu. of turnips. The butter during these two weeks was scored as first-class.

During the third week, when the amount of turnips was increased to 3 pecks per day, “the taint was scarcely perceptible upon the milk, although the butter from lot 1 (turnips fed before milking) showed a slight flavor of turnips.”

The fourth week 1 bu. of turnips per cow was fed daily. This week there was a decided flavor of turnips in the milk of both lots. At the commencement of the ripening process the cream from lot 1 was heated to 65° and 20 per cent of starter added, and that from lot 2 was heated to 75° and allowed to develop its own acid for 24 hours. “Lot 2 was scored low on account of the turnipy flavor, while lot 1 (turnips fed before milking) showed no turnipy flavor, indicating that the 20 per cent of starter added to the cream had overcome the turnipy flavor.” The butter from lot 3 maintained its good quality during the 4 weeks, notwithstanding the strong odor of turnips in the stable.

During the fifth week all 6 of the cows were given all the turnips they would eat. The mixed cream was divided into three equal parts, all of which gave a strong odor of turnips. The first lot was heated to 75° and allowed to ripen naturally, the second lot was heated to 65° and 20 per cent of starter added, and the third lot was pasteurized and 20 per cent of starter added. “The butter from the first lot was very strong with the flavor of turnips. Lot 2 was not so bad as lot 1, while lot 3 (pasteurized) showed no turnip flavor at all. This indicates that pasteurizing and adding a starter will overcome the turnipy flavors in milk and butter.”

The experiment was repeated April 6-27, the herd in milk at that time being divided into two lots, one fed turnips before milking and the other after milking. The amount of turnips was gradually increased until the cows were getting nearly 1 bu. per day.

The scoring of the butter made by the two lots and also from cream which received different treatment is given in the following table:

Quality of butter made when turnips were fed.

	Average score in flavor. (Max. 45.)			Average score in grain. (Max. 25.)			Average total. (Max. 100.)		
	First time.	Second time.	Average.	First time.	Second time.	Average.	First time.	Second time.	Average.
Turnips fed before milking.....	39	37	38	23	23	23	90.6	89.5	90
Turnips fed after milking.....	37.8	35.8	36.8	22.2	22.6	22.4	88.4	87.2	87.8
Turnip, cream pasteurized.....	40.75	40.0	40.37	23.2	23.0	23.1	93.7	92.0	92.8
Turnip cream not pasteurized, but a starter added.....	40.00	38.0	39.00	23.3	23.0	23.1	91.6	90.0	90.8
Turnip cream allowed to ripen of itself.....	36.0	33.0	34.5	21.6	23.0	22.3	86.0	85.0	85.5

“It will be noticed that pasteurization and the use of a starter improved the flavor very much.”

Effect of period of lactation on creaming of milk and quality of butter (p. 64).—The cows in the herd were divided into three lots according to the period of lactation. The average percentage of fat in the skim milk was 0.26 for the fresh milkers, 0.5 for those milked from 3 to 6 months, and 0.51 for those milked over 6 months. The time required for churning increased with the stage of lactation. The scoring of the butter on a basis of 100 was 93 for the fresh milkers, 92.2 for those milked 3 to 6 months, and 90.7 for those milked over 6 months, the difference being chiefly in the flavor.

Effect of straining milk through broken ice before setting (p. 64).—In June and July 12 trials were made of straining milk through broken ice and then setting it in a creamer in ice water as compared with adding 20 per cent of cold water to the cream, and of setting in the ordinary way.

“It was no advantage to strain the milk through ice before setting, nor yet to add cold water to the milk. This accords with previous experiments where both hot and cold water were added before setting.”

Milking machine compared with hand milking for quality of butter (pp. 64, 65).—On certain days about half the cows were milked with the Thistle milking machine and the other half by hand, butter being made from the milk of both lots. The scoring of the butter at 2 different dates is given.

“There was not so very much difference in the quality of butter when first made, but the machine butter spoiled, or went off in flavor, much more quickly.” (See also p. 290.)

Pasteurizing milk for butter making (pp. 65, 66).—Several trials were made in October, in which a vat of milk was heated to an average of 97° F., after which one-half of it was separated at once and the other half heated to an average of 158° F. and then separated.

“It was found that the cream was richer from the milk heated to 158°, and the feed had to be increased in order to prevent the cream outlet from clogging. The extra feeding did not increase the loss of fat in skim milk. All our experience goes to show that the capacity of a separator is increased and that it will skim closer by heating the milk to 100° or over before skimming.

“In churning the cream from the two temperatures for heating it was found that the cream from pasteurized milk churned in a little less time (average 3 minutes) and with less loss of fat in the buttermilk—0.13 per cent, as compared with 0.19 in the buttermilk from unpasteurized milk. . . .

“The quality of the butter is better where pasteurization is practiced. . . . If the cream is properly cooled for a sufficient length of time before churning, the grain of the butter will be all right.”

Pasteurized cream (p. 66).—Twenty trials were made in making butter from pasteurized cream as compared with cream not pasteurized. The scoring of the butter showed very little difference, although the butter from pasteurized cream kept slightly better.

Moisture in butter (p. 66).—The average of 48 samples of butter from the dairy department was found to be 11.034 per cent of water. The average water content of 14 samples, selected at random, was 11.297 per cent. Butter treated in a centrifugal butter dryer averaged 9.402 per cent of water, while the same butter handled in the ordinary way contained 10.125 per cent.

Temperature for ripening cream (pp. 66, 67).—Twenty-one trials were made, in which one lot of cream was ripened at an average temperature of 73° F., while the other lot was ripened at 60° F. It required 37 minutes to churn the former and 33 minutes to churn the latter. The percentage of fat in the buttermilk averaged 0.15 in the former case and 0.165 in the latter. The scoring of the butter gave no conclusive indications.

Different percentages of starter used to ripen cream (p. 67).—Thirteen trials, in which from 3 to 10 per cent of starter was added to one lot and about 11 per cent to the other, showed very little difference in the average results for the two lots, either in the loss of fat in the buttermilk or the quality of the butter.

Effect of washing butter (p. 68).—The results are given of 18 trials, in which the churning was divided into three parts, one part being unwashed, another washed once, and the third washed twice. The scoring of the butter showed less difference in favor of washing than last year (E. S. R., 9, p. 486).

Quality of butter made with centrifugal dryer (p. 68).—Half of the butter from the churning was put into the centrifugal dryer, which was revolved until no more moisture came from the butter, when it was removed, salted, and worked as usual. The other half of the churning was salted and worked in the ordinary way. As shown by the scoring of the butter, the quality “was practically the same for both methods.”

Sweet and dent corn for milch cows, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 83, 84*).—An experiment was made

with 4 cows to compare the value of green sweet and dent corn for the production of milk. Previous to the commencement of the experiment the cows were on clover pasture and received in addition a pound of a mixture of bran and oil meal, 1:1, per day.

"During the first 10 days of the experiment the cows were fed green corn alone, cows 1 and 2 receiving sweet corn and cows 3 and 4 dent corn. At the end of 10 days 4 lbs. of meal were fed to each cow per day and the meal ration continued throughout the remainder of the experiment, or a period of 11 days. The meal ration consisted of equal parts by weight of barley, shorts, and oil meal. The variety of sweet corn used was Evergreen Sweet and the dent corn was Mammoth Cuban. . . . The cows did not eat the dent corn so readily as the sweet, and for a time wasted a considerable quantity of it, the waste becoming less as time went on."

The amount of green corn fed, eaten, and wasted, and the yield of milk during each period and for the 6 days immediately preceding and following the test are tabulated. The author states that "when fed corn alone the dent-corn group suffered a greater shrinkage in milk yield than the sweet corn group;" that "when meal was added to the ration both groups increased in milk yield, but the sweet-corn group increased slightly more than the dent-corn group;" and that "when returned to pasture both cows of the sweet-corn group decreased in milk yield, while both cows of the dent-corn group slightly increased in milk yield." The superiority of the sweet corn is thought to be due to its greater palatability, "since the cows on sweet corn consumed more corn per hundred pounds of live weight than those on dent corn."

"There is one more important consideration. The sweet corn yielded at the rate of 29,280 lbs. of green fodder per acre, while the dent corn yielded at the rate of 36,376 lbs. per acre. . . . This greater yield of dent corn more than compensates for what is lost when compared with sweet corn for milk production, and therefore this experiment would indicate that the dent corn proved more economical than the sweet."

Machine-drawn milk vs. hand-drawn milk—some bacteriological considerations, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 128-132, figs. 2*)—A bacteriological study was made of the milk drawn with the Thistle milking machine and of that milked by hand. The investigations were made each month from April to August, inclusive.

"The average number of germs per cubic centimeter in the morning's milk from the machine for 16 weeks was 141,595, while the average in the hand milk for 14 weeks was 10,619—a result largely in favor of the hand milk. The average for the evening's machine milk was 165,033, and for the hand milk, 12,890—a result almost as much in favor of the hand milk. . . .

"A considerable variety was found in the machine milk, over 25 species being separated by the usual bacteriological methods, and all grown in pure culture in sterilized milk. . . .

"The germs in the hand milk were, generally speaking, of the same kinds as were found in the machine milk, but in the machine milk the putrefactive species (those that liquefy gelatin) were very much more numerous and varied."

The large number of bacteria found in the milk drawn with a machine is attributed to the following causes:

“(1) Germs on the hairy portion of the udder, drawn into the pail by the pulsation of the teat cups, etc.

“(2) Inability to cleanse thoroughly the cups and rubber connections.

“(3) The occasional falling of cups upon the stable floor, and constant contamination from material full of germ life.

“The infection under 1 and 3 may, we think, be largely prevented by due care on the part of milkers; and it is possible that the makers of the machine will devise some means of overcoming the difficulty about cleaning and disinfecting the udder cups and tubes.”

Effect of the germs isolated from machine milk on the flavor and other qualities of butter, F. C. HARRISON and M. N. ROSS (*Ontario Agr. Col. and Expt. Farm. Rpt. 1897, pp. 133-140*).—Cultures of the germs isolated from milk drawn with the Thistle milking machine were used in preparing starters for ripening the cream, and butter was made from this cream in small lots. The data for these experiments, including a description of the cream before churning and the general quality and scoring of the butter, are tabulated, together with descriptions of the various species. In a few cases the butter was rated as fair, but in most cases it was off flavor and did not keep well.

“These experiments have shown that the number of undesirable germs in the ‘machine’ milk far exceeds that of those which are desirable. . . .

“Briefly, the germs isolated from the machine milk were 16 per cent more injurious than those isolated by Conn (his conditions being taken as normal.)

“The only practicable method of overcoming these bad effects is by thorough pasteurization of the cream and the addition of a good starter, produced from pasteurized milk to which has been added either good buttermilk from an excellent flavored butter, or, failing this, a culture obtained from some recognized source and which is known to be good.”

Experiments in cheese making, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 11-59*).—Many of these experiments are in continuation of work reported the previous year (*E. S. R., 9, p. 481*).

Relation of fat in milk to quantity and quality of cheese (pp. 41-49).—During the year 27 experiments were made in each of which the milk was divided into different lots according to its fat content. The data for the experiments are given in detail and the averages of these data are summarized below:

Yield and quality of cheese from richer and poorer milk.

Group.	Fat content of milk.		Milk required to make 1 lb. of cheese.	Cheese produced from 1 lb. of fat in milk.	Fat content of whey.	Quality of the cheese.				
	Range.	Average.				Flavor (max. 35).	Closeness (max. 20).	Even color (max. 15).	Texture (max. 20).	Average total score (max. 90).
	<i>Per cent.</i>	<i>Per ct.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Per ct.</i>					
1.....	Below 3	2.88	11.529	3.01	0.225	28.33	18.16	14.16	16.83	77.48
2.....	3.00 to 3.50	3.26	10.968	2.79	.247	28.43	17.93	13.70	17.00	77.06
3.....	3.55 to 4.00	3.81	10.013	2.62	3.29	29.81	18.25	13.56	17.25	78.87
4.....	4.05 to 4.50	4.23	9.677	2.44	3.25	29.75	18.00	13.00	17.25	78.00
			10.512	2.70						

The following conclusions were reached:

“(1) The yield of cheese per 100 lbs. of milk increased when the percentage of fat increased, but it did not increase in exactly the same proportion.

“(2) The yield of cheese per pound of fat in the milk decreased as the percentage of fat increased.

“(3) The yield of cheese is fairly proportionate to the fat and casein in the milk. The casein may be represented by the figure 2 added to the percentage of fat in the milk.

“(4) The highest average score of cheese made was in the group where the milk ranged from 3.55 to 4 per cent of fat.

“(5) The [rich milk] cheese lost 3.1 per cent in weight while curing; the [medium and poor milk] cheese lost 3.3 per cent.

“(6) The loss of fat in whey, drippings, and pressings was greater from the rich milk. This is especially marked in the drippings after salting, which include the grease pressed out of the cheese while in the hoops. The loss of fat at this stage is nearly double that from medium and poor milk.

“(7) In those experiments where the percentage of casein was determined it showed a greater average loss of casein at each stage of the making from the [rich] milk as compared with the [medium and poor] milk.

“(8) We recommend the percentage of fat + 2 system for distributing proceeds among patrons of cheese factories.”

Rapid curing cheese vs. slow curing cheese (pp. 49, 50).—During May and June 30 trials were made to compare the effect of using an extra quantity of rennet and less salt with the usual amounts of these. The general qualities of the cheese and its keeping quality were observed.

“In the spring of the year, when it is usually the best policy to make cheese which will cure or ripen quickly, we advise the use of 4 to 5 oz. of rennet per 1,000 lbs. of milk, or sufficient to cause coagulation in 20 to 25 minutes. Less salt—say 2 lbs. per 100 lbs. of curd or per 1,000 lbs. milk—may also be used. . . .

“Where the extra amount of rennet and the small quantity of salt were used the cheese ripened and went off in flavor more quickly.”

Stirring curds (p. 50).—To test the suggestion that “curds need not be stirred so much if an extra quantity of salt were applied,” 7 trials were made during September and October. In each trial both lots of milk were treated exactly the same, except that one lot was not stirred after dipping but an extra quantity of salt was added to the curd.

“(1) By not stirring the curd there was an extra pound of cured cheese made from 600 lbs. of milk.

“(2) The quality of the two cheeses was much alike.

“(3) With a small curd the extra salt applied seemed to have the same effect as hand stirring of the curd.”

Aeration of milk for cheese making (pp. 50, 51).—During July, August, and September, 15 experiments were made, in each of which a vat of aerated and another of unaerated milk was used.

“While the average of the results did not indicate much difference in the yield or quality of the cheese, nor did aerating the milk prevent the formation of gas, yet the gas was easier got rid of from the aerated milk curds; and in case of badly flavored milk, the aeration made an improvement in the yield and quality of the cheese.

“We shall need to make further experiments before making any very definite statements about the effects of aeration on milk for cheese making. In the meantime we advise aeration in or with a pure atmosphere.”

Pasteurizing milk for cheese making (pp. 51, 52).—Cheese was made from pasteurized milk with and without a starter, the milk being made up into cheese the same day as pasteurized in some cases and in others the following day.

“The heating of the milk to 160° changes the character of the milk in such a way that it does not work at all like an ordinary Cheddar curd. The cheese made from pasteurized milk resembles Stilton cheese in many respects; in fact our experiments point to a new and successful method of making a famous Stilton cheese.

“The cheese made from heated milk to which a starter was added more nearly resembled an ordinary Cheddar. The experiments so far made would lead us to doubt the value of pasteurization for Cheddar cheese making. In every case where the milk was kept over until the following day the curds were very gassy.”

Ripening milk before adding rennet (p. 52).—The results are given of 8 trials made during May and June. The rennet test varied from 13 to 31 seconds.

“The general rule seems to be that a difference of one second in the rennet test will make a difference of about two minutes in the time required for coagulation, although there are some marked exceptions to this rule.”

Effect of different quantities of rennet (pp. 54, 55).—Several experiments were made in which milk ripened to a rennet test of about 22 seconds was treated with varying quantities of rennet ranging from 1 oz. to 8 oz. per 1,000 lbs. of milk.

“(1) Where less than 3 oz. of rennet per 1,000 lbs. of milk was used there was an extra loss of fat in the whey and less cheese made. The extra quantity of rennet, above 3½ oz., made an extra yield of cheese.

“(2) The highest scoring cheese was made using 2½ and 3 oz. of rennet per 1,000 lbs. milk.

“(3) The time required for coagulation decreases with an increased quantity of rennet used in the milk.”

Effect of dipping at different stages of acid (pp. 55, 56).—A number of trials on this subject were made during June and July with the following results:

“(1) The time from setting to salting was about the same, irrespective of the time which the curds were allowed to remain in the whey.

“(2) The yield of cheese was greater by dipping at about ¼ in. of acid, or 0.2 per cent, than where the curds were allowed to remain until over ¼ in. of acid showed on the hot iron.

“(3) The percentage of fat in the drippings (whey from milling until the cheese are removed from the press) was higher in all cases where the curd remained in the whey for a long time.

“(4) The quality of the cheese was better in nearly every case from dipping at ¼ to ½ in. of acid as shown on the hot iron.”

Milling the curd (pp. 56, 57).—Nine experiments were made in each of which the curd was divided into 2 parts before milling, one-half being milled at about 1 hour and 40 minutes after dipping, when the hot iron indicated about 1 in. of acid, and the other half at periods ranging from 1 to 3 hours after dipping.

“(1) About 1½ in. was the longest ‘string’ which could be got on the hot iron. After this the ‘strings’ went back.

“(2) Whether milled at 1½ hours after dipping, or longer, the curds were ready to salt at about the same time.

“(3) Allowing the curds to remain for 2½ to 3 hours after dipping, and before milling, causes a greater waste of butter fat than milling earlier.

“(4) There did not appear to be so very much difference in the quality of cheese produced from the two methods.

“(5) We recommend milling about 1½ hours after dipping, or when the curd becomes meaty and shows ¾ to 1 in. of acid on the hot iron.”

Salting curds 1 hour sooner than usual (pp. 57, 58).—During April, May, June, September, and October 15 experiments were made, one-half of the curd being salted about 1 hour sooner than the other half, which was allowed to develop the “velvety” feel.

“(1) The yield of cheese per 100 lbs. of milk was slightly greater by salting one hour before the curds became ‘velvety.’

“(2) The loss of fat in pressings and drippings was slightly greater by allowing the curds to ‘mellow down’ before salting.

“(3) There was not much difference in the quality of the cheese whether salted early or late, what difference there was being in favor of mellowing the curds before salting.”

Temperature of curds at time of putting to press (pp. 58, 59).—In 9 experiments the curd was divided, the two parts being put to press at different temperatures.

“The range of temperature was from 62° to 95° at the time of hooping. The highest scoring cheese was made from a curd put to press at 93°. Last year there was more openness in the cheese put to press at a high temperature. This difference did not seem to be so marked this year.

“So long as the press room is kept moderately warm there does not seem to be much difference in the quality of the cheese whether put to press at 65° or 95°, or at any temperature between these two points.”

Bad flavor in cheese caused by undesirable bacteria in water used in factory, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 111-144*).—The case of a factory where cheese of a bad flavor was being made was investigated. The cheese maker was said to be a good maker and the factory in first-class condition. A bacteriological examination of the water showed a very large number of germs present, from which 5 different species were isolated. The germs isolated from the water and the cheese were compared, and 2 of the species found in the water were discovered to be identical with 2 found in the cheese, but 1 was in such small numbers that it was disregarded. The biological characteristics of the other germ are described, together with an experiment in which cheese was made from pasteurized milk inoculated with a culture of this germ. This cheese proved to be of bad flavor, and the germ previously found in the cheese and water was isolated from it. The cheese maker was advised to stop using the water, and the report soon came that the cheese was all right.

Miscellaneous dairy notes, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1897, pp. 71-80*).—These include a reprint of newspaper bulletins on fodder and spring cheese, the curing of cheese, and the winter creamery; and notes on milk tests at fairs, square cheese, the milking machine, the air process in butter making, working

over old butter, tests of cows, etc. Some experimental square cheeses sent to London brought satisfactory prices, but "the shape was not suitable for the London trade." With regard to the Thistle milking machine it is stated that "it milked the cows clean, and after a few times use nearly all of the cows seemed to enjoy being milked by it as well as by hand. The greatest trouble we had was with the flavor of the milk. The pipes through which the air is forced by the machine become very foul from the milk drawn into them whenever a cup drops from a teat. I believe that this difficulty has been remedied."

A trial of working over stale butter resulted in very little improvement.

General system of feeding the dairy herd, W. P. WHEELER (*New York State Sta. Rpt. 1896*, pp. 639-641).—General remarks on the character of the rations fed to the dairy herd at different times during the year.

Concerning Russian dairy cattle. Observations and experiments on the productiveness of a dairy herd during a period of six years (1889-1894) at the Edium school of dairying, N. V. VERESHCHAGIN and A. A. POPOV (*Moscow, 1896*, pp. 38-179, *dgms. 3; abs. in Selsk. Khoz. i Lysov., 184 (1897), Mar., pp. 702, 703*).

Dairy stock, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, pp. 69, 70).—This is a record of the herd for the year, showing the yield and cost of milk, butter, and cheese for each cow.

Green rye and alfalfa for milch cows, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, p. 85).—Rye and alfalfa were compared as soiling crops for milch cows. No details of the experiment are given. The general conclusions, summarized by the author, are as follows:

"The rye, which was a medium crop, yielded at the rate of 12,375 lbs. of green fodder per acre and the alfalfa yielded a first cutting at the rate of 15,300 lbs. of green fodder per acre. The alfalfa was eaten rather more readily by the cows than the rye. The milk yield was slightly in favor of the alfalfa. When scored by an expert the rye butter scored 35 points for flavor and the alfalfa butter 40 points for flavor, out of a possible score of 45 points. The plat of alfalfa furnished 2 subsequent crops, which made the total yield from the alfalfa plat more than double that stated above, whereas the rye made but an indifferent second growth."

Oats and peas and peas and tares for milch cows, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, pp. 84, 85).—A comparison was made of green oats and peas and oats and tares for milch cows. The seed was mixed in the proportion of 2 bu. of oats to 1 of peas and 2 bu. of oats to 1 of tares. Two cows were fed on each ration. Only the general conclusions are given. Both fodders were eaten readily and neither could be said to excel the other as a milk producer.

"The oats and peas yielded at the rate of 14,760 lbs. of green fodder per acre and the oats and tares 14,688 lbs. per acre."

Effect of drought upon milk production, L. L. VAN SLYKE (*New York State Sta. Rpt. 1896*, pp. 37-65).—This is the same as Bulletin 105 of the station (E. S. R., 8, p. 825), with detailed tabulated data not given in the bulletin.

Milk fat and cheese yield, L. L. VAN SLYKE (*New York State Sta. Rpt. 1896*, pp. 66-106).—This is the same as Bulletin 110 of the station (E. S. R., 9, p. 181), with some detailed tabulated data not given in the bulletin.

Analyses of butter, A. L. WINTON, A. W. OGDEN, and W. L. MITCHELL (*Connecticut State Sta. Rpt. 1897*, pp. 322, 323).—Analyses are reported of butter from England (Dorsetshire), Denmark, Normandy, Australia, Brittany, and Ireland, and from the Vernon Creamery, Connecticut. The butter from Normandy, Australia, Brittany, and Ireland "gave a decided reaction for boric acid, probably present in the form of borax." The samples were scored on the basis of flavor, grain, color, salt, and package.

Machine-drawn milk for cheese making, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, p. 141).—Two small cheeses were made from milk drawn with the Thistle milking machine. "The curd was gassy, there was great loss of fat at salting, and the curd had a very bad flavor. [A month later] the flavor was scored 20 and 26, respectively, out of 35."

VETERINARY SCIENCE AND PRACTICE.

Report of the veterinary department, A. W. BITTING (*Indiana Sta. Rpt. 1897, pp. 11-50*).—It is stated that studies have been made along the lines of the water supply for the live stock in the State; hog cholera; tuberculosis; the treatment of contagious abortion among cattle; the fecundity of swine (p. 280); the relative frequency of the occurrence and distribution of diseases of stock in the State; sheep dips; and the embryology, anatomy, and physiology of the mammary gland.

On the subject of tuberculosis it is noted that some 2,000 cattle have been tested since the station took up the work. The experiments with sheep dips resulted in showing that chloro-naphtholeum, zennoleum, Potter's Perfection Dip, and Daytholeum are effective in solutions of 1 per cent. In the study of diseases 2,975 cases of lameness, 587 of fistulae, 28 of bursae, 29 of cornstalk disease, 59 of cerebro-spinal meningitis, 528 of parturient apoplexy, 268 of periodic ophthalmia, 250 of pleurisy, 543 of pneumonia, 489 of laminitis, 217 of enteritis, 266 of gastritis, 2,042 of colic, 759 of azoturia, 502 of canine distemper, 67 of specific ophthalmia of cattle, 30 of sporadic aphthae, 218 of tetanus, 67 of tuberculosis, 2,608 of influenza, 12 of rabies, 24 of glanders, 42 of abortion in cows, 15 of abortion in mares, 8 of anthrax, and 120 of actinomycosis were found. The table given shows little difference in the number of cases occurring in the different months of the year, with the exception of azoturia, which was most frequent in January, February, and March. The loss from hog cholera during 1897 was only about 70 per cent as great as in 1896. The townships bordering upon the rivers lost 50 to 70 per cent more than those lying farther back.

Report of the veterinary science section, M. STALKER and W. B. NILES (*Iowa Sta. Rpt. 1896-97, pp. 131-144*).—After mentioning the general plan of organization of work it is stated that Texas fever has, through legislation, ceased to be feared; that glanders and farcy among horses have been practically exterminated in the State, although some dozen years ago about half the counties of the State were affected; and that tuberculin has been successfully used in diagnosing tuberculosis and with systematic application of the best knowledge of the subject there is promise of favorable final results. Swine plague and hog cholera, cornstalk disease, and pseudo-rabies are discussed. Appended are articles on hog cholera and swine plague and on bovine tuberculosis.

Animal diseases, A. T. PETERS (*Nebraska Sta. Rpt. 1897, pp 13-17*).—The author makes brief notes on the occurrence of actinomycosis, which has been reported in only a very few instances; anthrax, which has appeared in Polk County; black leg; cornstalk disease; keratitis; glanders, which has been reported from 16 counties; rabies, which in Otoe County affected 10 hogs, 2 cows, a mule, and a horse; tuberculosis, and hog cholera. The cornstalk disease seems to have affected horses to a greater extent than in former years. It is noted that it may be prevented to a certain extent by feeding something else than cornstalks before the animals are turned into the field. Keratitis has appeared among cattle in certain localities, affecting

animals mostly while in pasture. The disease is described by stockmen as follows: "The animal will be seen to be uneasy, and if the left eye is affected will hold the head down and try to drive away with the left foot the object that seems to it to be on or covering the eye."

Tuberculin, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Rpt. 1897*, pp. 144-149, figs. 3).—Tuberculin for official herd testing in Ontario is now manufactured and sent out by the college. Directions are given for making the test, and the summarized results secured in the testing of 502 animals of different breeds during 1897 are tabulated. The danger of using milk from tuberculous cows is discussed and notes given on three clinical examinations of guinea pigs inoculated with milk from tuberculous cows. The guinea pigs either died or were killed in from 8 to 10 weeks after inoculation and in every instance were found tuberculous.

On the means of protecting domestic animals from infectious diseases, R. LETZ (*Selsk. Khoz. i Lyesor., 186 (1897), Sept., pp. 613-634*).

STATISTICS—MISCELLANEOUS.

Reports of director and treasurer of California Station, 1895-1897 (*California Sta. Rpt. 1895-1897*, pp. XVI + 329, 346, 347, 363, 364, 427-455).—Treasurer's report for the fiscal years ending June 30, 1896 and 1897; directions for sending samples to the station for examination; organization list; list of donations to the station; exchange list, and reports on the work at the Southern Coast Range, San Joaquin Valley, and Southern California Culture Substations, management, local problems, etc.

Twenty-first Annual Report of Connecticut State Station, 1897 (*Connecticut State Sta. Rpt. 1897*, pp. XV).—Notices relative to the availability of the bulletins and reports of the station; list of the officers and staff for 1897; announcements as to the nature of work undertaken for outside parties; report of the secretary of the board of control of the station on the work of the year, and a report on the changes in the experiment station grounds necessitated by the laying out of certain new streets.

Tenth Annual Report of Indiana Station, 1897 (*Indiana Sta. Rpt. 1897*, pp. 1-15, 60-69).—Report by the director on the experimental work carried on by the different departments during the year, improvements, pamphlet and newspaper bulletins published, mailing list, and an inventory of station live stock. The appendix to the report contains lists of acknowledgments and exchanges and a financial statement for the fiscal year ending June 30, 1897.

Reports of director and treasurer of Iowa Station, 1896-97 (*Iowa Sta. Rpt. 1896-97*, pp. 102-105, 145, 146).—Brief notes on the work of the station during these two years, with a general review of the bulletins published (32-35), and a financial statement for the fiscal years ending June 30, 1896 and 1897.

Eleventh Annual Report of Nebraska Station, 1897 (*Nebraska Sta. Rpt. 1897*, pp. 40).—A report by the director on the station staff, improvements during the year, lines of experiments carried on, cooperative work, farmers' institutes, publications of the station in 1897, mailing list, etc.; and by the agriculturist, veterinarian, botanist, chemist, entomologist, geologist, horticulturist, and meteorologist on the work of their respective departments during the year, some of the details of which are noted elsewhere; and a financial statement for the fiscal year ending June 30, 1898.

Ninth Annual Report of Nevada Station, 1896 (*Nevada Sta. Rpt. 1896*, pp. 28).—Contains the organization list of the station; brief reports by the director and heads of departments on the work of the year, and a financial statement for the fiscal year ending June 30, 1896. In addition to other matter the report of the agriculturist contains brief suggestions on the culture of corn under Nevada conditions. A poisonous plant (*Zygadenus paniculatus*), which has caused the death of several range cattle, is briefly noted.

Reports of director and treasurer of New York State Station, 1896 (*New York State Sta. Rpt. 1896*, pp. VIII 1-34, 688-694, 719-752, pls. 5).—Treasurer's report for the fiscal year ending September 30, 1896; station organization list; reprint of the report of the director, published as Bulletin 115 of the station (E. S. R., 9, p. 197), and lists of acknowledgments and exchanges.

The world's production of cereals, L. GRANDEAU (*Jour. Agr. Prat.*, 2 (1898), No. 38, pp. 45-49).—Statistics on the production of wheat, rye, oats, barley, and corn.

The agriculture of Finland, its development and present state (*Rpt. Imperial Senate of Finland. Helsingfors, 1896*, pp. 389, figs. 11, dgm. 6, maps 5; abs. in *Selsk. Khoz. i Lyesor.*, 184 (1897), Feb., pp. 470-472).—Describes chiefly the organization and activity of the Department of Agriculture of Finland.

History of the Imperial Moscow Society of Agriculture during the past 75 years (December 20, 1820-December 20, 1895), A. P. PERYEPYOLKIN (*Moscow, 1896*, pp. 165 + 239 + 72, figs. 5; abs. in *Selsk. Khoz. i Lyesor.*, 187 (1897), Dec., p. 671).

Sketches from the history of agriculture in southern Russia, A. GROTO-HYEPHKOVSKI (*Selsk. Khoz. i Lyesor.*, 185 (1897), Apr., pp. 39-94).

Index of agricultural scientific institutions based on information up to January 1, 1897 (*Rpt. Min. Agr. and Govt. Estates. Div. Rural Econ. and Agr. Stat. St. Petersburg, 1897*, pp. XXIV + 194; abs. in *Selsk. Khoz. i Lyesor.*, 187 (1897), Oct., p. 231).—The total number of scientific institutions under the jurisdiction of the Department of Agriculture is 108, with 5,000 students. Of these 2 are higher schools, 11 secondary, and 95 lower.—P. FIREMAN.

The year 1896 from the standpoint of agriculture according to reports from farmers, VI (*Rpt. Min. Agr. and Govt. Estates. Div. Rural Econ. and Agr. Stat. St. Petersburg, 1897*, pp. LVIII - 94; abs. in *Selsk. Khoz. i Lyesor.*, 185 (1897), May, p. 480).—The report contains a survey of the prices of agricultural products, live stock, and the products of stock raising, and also a chapter on the influence on prices of the crop of 1896.—P. FIREMAN.

Index to authors, with titles of their publications, appearing in the documents of the United States Department of Agriculture, 1841-1897, G. F. THOMPSON and G. W. HILL (*U. S. Dept. Agr., Division of Publications Bul. 4*, pp. 303).

The work of the college of agriculture and experiment stations, E. W. HILGARD (*California Sta. Rpt. 1895-1897*, pp. 3-19).—A revised reprint of Bulletin 111 of the station (E. S. R., 8, p. 735).

The Minnesota plan for agricultural teaching, R. H. LOUGHRIDGE (*California Sta. Rpt. 1895-1897*, pp. 19-22).—A discussion of the desirable features of the School of Agriculture of the University of Minnesota and on the practical results and success of the school.

Farmers' institutes in California, E. J. WICKSON (*California Sta. Rpt. 1895-1897*, pp. 23, 24).—A brief report on the institute work of 1896. Meetings were held in 52 localities during the year.

Changes in the rates of charges for railway and other transportation services, J. HYDE and H. T. NEWCOMB (*U. S. Dept. Agr., Division of Statistics Bul. 15, misc. ser.*, pp. 80).—A comprehensive historical report extending over a period of 50 years, and dealing with the charges on railways, canals, and waterways for the transportation of agricultural products, etc., to the principal markets and seaports in the United States, and containing certain tabular data relative to passenger rates.

NOTES.

COLORADO STATION.—Elmer D. Ball has succeeded Emma Gillette as assistant entomologist, and Carl H. Potter has succeeded Jacob H. Cowen as assistant horticulturist.

IDAHO COLLEGE AND STATION.—J. P. Blanton has been appointed president of the University of Idaho and director of the Station, *vice* F. B. Gault. H. T. French, formerly of the Oregon Station, has accepted the position of professor of agriculture in the college and agriculturist of the station. Thorn Smith, formerly first assistant chemist of the Michigan Station, has accepted a similar position with the Idaho Station. Prof. A. S. Miller has been added to the station staff as geologist. A commodious greenhouse and horticultural building has been erected. The chair of horticulture has been created and F. A. Huntley appointed to the professorship. Ashby Turner has resigned as a member of the governing board and James H. Hawley, of Boise, has been appointed in his place.

ILLINOIS STATION.—The station has recently begun publishing abstracts of its more technical bulletins. The full bulletin will be issued in a limited edition and sent only to scientific readers upon request, while the abstract will be sent to all names upon the regular mailing list.

INDIANA STATION.—A new stave silo 28 ft. high and 12 ft. in diameter has recently been erected. A. H. Bryan, a graduate of Purdue University in the class of 1898, has been appointed assistant chemist, *vice* J. M. Barrett, resigned.

IOWA COLLEGE.—Farmers' excursions have been inaugurated at the college. The first excursion was held August 17, and the occasion was a marked success in every particular. About 6,000 people were in attendance. It is believed these excursions will result in more cordial and friendly relations between the college and the people of the State.

KANSAS STATION.—R. W. Clothier has been appointed assistant chemist of the station. The studies on soil moisture have been continued and additional experiments commenced to test the effect of various fertilizers upon moisture conservation. Digestion experiments have been made with alfalfa at three stages of growth and with prairie hay. The veterinary department is distributing blackleg vaccine to the stock owners of the State. During the first half of October, 3,500 double doses were sent out. Experiments in protective inoculation for swine plague are in progress. The virus used is that prepared by H. J. Detmers. A press bulletin on the sand plum, one of the most valuable native fruits of Kansas, has been distributed.

MAINE STATION.—Otis Meader has been added to the governing board. Miss Mary Hutchinson has been appointed clerk, *vice* Mrs. J. Hamlin Waite.

NEBRASKA STATION.—The board of regents has authorized the making of analyses of 10,000 mother beets grown upon the experimental plat at Ames, Nebraska. C. H. Elmendorf, of the station, served as acting superintendent of the live-stock department of the Omaha Exposition, and T. L. Lyon was in charge of the dairy tests.

NEW HAMPSHIRE COLLEGE AND STATION.—Charles W. Burkett, of the Ohio State University, has been elected associate professor of agriculture of the college and agriculturist of the station.

NORTH CAROLINA COLLEGE AND STATION.—Dr. Cooper Curtice has been appointed veterinarian and biologist in the college and station. F. E. Hege, poultry manager

of the station, has resigned. The work of this department will be carried on under the supervision of the director and the agriculturist. A. W. Blair has been appointed State chemist, and will have charge of the analyses for the fertilizer control and for the general public under the supervision of the director.

OREGON STATION.—James Withycombe has been appointed assistant director and agriculturist of the station.

PENNSYLVANIA STATION.—W. S. Sweetser, assistant chemist, terminated his connection with the station October 1, 1898, to accept a position as assistant instructor in agriculture in Hampton Normal and Agricultural Institute. M. S. McDowell, A. M. Diehl, and Charles Beistle have been appointed assistant chemists of the station. At its annual meeting in June the board of trustees established two fellowships—one in dairy husbandry and one in agricultural chemistry. These fellowships were filled, after competitive examination, by the appointment of J. D. Huston and W. A. Hutchison, respectively, graduates in agriculture of the class of 1898. The purpose of the fellowships is to utilize the facilities for advanced work of a high grade in agriculture which are available in connection with the work of investigation carried on at the station. The "fellows" are to devote a portion of their time to the regular work of the experiment station and the remainder to advanced study and investigation. Arrangements have been made by which the United States Department of Agriculture and the station are to cooperate in the construction of a respiration calorimeter for experiments with domestic animals and the prosecution of scientific investigations into the principles of animal nutrition.

SOUTH CAROLINA COLLEGE AND STATION.—G. E. Nesom has been appointed veterinarian, *vice* W. E. A. Wyman; B. F. Robertson has succeeded John Thompson as assistant chemist at the station; and Ernest Walker has been appointed assistant horticulturist and entomologist. Special experiments are being made on the effect of different forms of potash, including silicate, on several crops, especially on the starch content of roots and tubers and on the burning quality of tobacco. The injurious effect of the inoculation of the soil by certain legumes on the subsequent growth of other kinds of legumes is also being studied.

VERMONT COLLEGE AND STATION.—G. H. Perkins and J. L. Hills have been elected deans of the departments of natural history (including chemistry, physics, and biology) and of agriculture, respectively. L. R. Jones and F. A. Waugh have been granted a half year's leave of absence for special studies in botany and horticulture.

WYOMING STATION.—A small potting house 18 by 16 ft. has been added to the greenhouse plant, and the dwelling house on the farm has been improved by certain additions. The farm equipment has been increased by the purchase of a Deering Ideal mower, a bone and grain mill, and a 4-horsepower portable gasoline engine. Much interest is manifested among the farmers in the forage crops being grown upon the station farm. Flat pea stands drought well and produces large crops, but so far stock will not eat it either in the green or dry state. It has not yet been offered to sheep. The success of alfalfa in this region is assured when planted with a press drill and otherwise properly handled. Another season the farmers will plant larger areas to it. Hairy vetch is also very promising, and sanfoin does exceedingly well.

PERSONAL MENTION.—Dr. F. Noll has become professor of botany at the Royal Agricultural Academy of Poppelsdorf, as the successor of Professor Körnicke, retired.

Dr. Oscar Loew, formerly connected with the College of Agriculture of the Imperial University of Japan, but later of Munich, has been appointed to a position in the Division of Vegetable Physiology and Pathology of this Department.

EXPERIMENT STATION RECORD,

EXPERIMENT STATION RECORD.

VOL. X.

No. 4.

The following statements regarding the labors of Dr. E. Lewis Sturtevant, one of the earlier agitators for experiment stations in this country and an active student and investigator of agricultural problems, are furnished by Prof. C. S. Plumb, who was for several years associated with him in his work at the New York State Experiment Station. For years Dr. Sturtevant was a prominent figure in movements for the benefit of agriculture, and devoted himself enthusiastically to the advancement of both the science and the art. During the later years of his life, when prevented by failing health from active participation in experiment station work, he continued his studies and investigations at his home and prepared for publication some of the material which he had gathered in the form of notes during the busier periods of his life. In this way the results of his extensive studies on the varieties of corn were brought together and arranged for publication as a bulletin of this office, now in press. In this extensive monograph the several hundreds of varieties have been described and systematized, the classification followed being the one previously published by Dr. Sturtevant. The synonymy has been much reduced, clearing up the confusion of varietal names of corn and placing the nomenclature on a sound scientific basis.

The recent death of Dr. E. Lewis Sturtevant, on July 30 last, marks the passing of one who has occupied a pioneer and important place in the history of agricultural research in America. Born in Boston in 1842, educated in the best schools of the East, and receiving degrees from Bowdoin College and the Harvard University Medical School, he was equipped with a training that enabled him to be of great service to his fellows.

After serving for a time in the Civil War, during which he was promoted to the captaincy of his company in the 24th Regiment of Maine Volunteers, sickness caused his retirement to civil life, and he took up the study of medicine at Harvard, where he graduated in 1866. Being of independent means, he returned to the home farm at South Framingham, Massachusetts, some 25 miles west of Boston, where he began the agricultural studies which continued during the rest of his life. Here, on "Waushakum Farm," the joint property of his brother and himself, he took up a study of dairying and the Ayrshire breed of cattle, bred

and improved a variety of yellow flint corn named after the farm, and otherwise engaged himself in agricultural problems. His milk investigations early in the seventies attracted considerable attention, and he lectured before prominent societies in 1873-74, discussing the physiology of milk, and bringing out striking differences in size of fat globules in milk of several breeds of cows, as found by him in microscopical examinations. The subjects of corn culture, farm fertility, and dairying attracted his chief attention, and he became widely known over New England and the Middle States as a prominent agricultural investigator and lecturer.

Dr. Sturtevant early recognized the importance of a more intelligent farming practice, which could be greatly promoted through the aid of boards of agriculture, experiment stations, and agricultural schools and colleges, and was a prominent leader in the agitation for the establishment of experiment stations. In an address before the Middlesex South Agricultural Society in 1872 he said: "Every agricultural society should be an experimental station. No matter how few or how many facts or discoveries it makes, each one should have the precision and form which would enable it to be used in connection with other facts derived from other sources. The common facts of the farm are comparatively unknown. What is a day's labor at any kind of work? What is the effect of various kinds of food? What is the comparative value of various feeds used on our farms? What is the usual yield of a good milch cow? These and other simple questions, which should have been determined long ago, still remain practically unanswered. The constants of agriculture are yet to be given."

In 1882 he was invited to become director of the New York State Experiment Station at Geneva, New York, just established, which position he held for 5 years, resigning in 1887. The duty devolved upon him of organizing the new institution, outlining the work, equipping laboratories, planning field and laboratory experiments, and establishing a working, coherent experiment station. This Dr. Sturtevant did on a more extensive plan than was attempted by any other American station in operation at that period. He proved himself a good organizer of work and an efficient manager of men. He gathered about him an excellent corps of workers, nearly all of whom have since been among the leading workers in the experiment stations of this country. He personally planned extensive field work with standard farm crops, and especially the cereals, devised feeding experiments with dairy cattle, and directed large experimental work in the vegetable garden.

The first six reports of the New York State Station, issued under his direction, contain much information on live agricultural problems, and show marked activity on the part of the station working force. When he resigned his place at Geneva, it was to go back to his home, to remain in retirement, for a number of years an invalid.

Dr. Sturtevant's influence on agriculture from the educational or

scientific standpoint was significant. His published writings number several hundred titles. He was the author of many addresses that were widely read. For several years he partly or entirely edited the *Scientific Farmer*. With his brother Joseph he was author of a book on the Ayrshire cow that contains much valuable information concerning this breed. He was one of the original founders of the Society for the Promotion of Agricultural Science, and took an active interest in its work up to his final illness. He made a special study of maize for over 20 years and was the best authority on the history and characteristics of this plant. He gave great attention to the edible plants, had collected the most complete pre-Linnean library in America, and was an authority on the history of garden vegetables. During the last 10 years of his life while in health he gave much time to the study of plant history and was a frequent contributor on this subject to the *American Naturalist*, the *Botanical Gazette*, and *Torrey Botanical Club Bulletin*.

Dr. Sturtevant was a man of great fertility of mind, active temperament, and enthusiasm for his work. He was constantly accumulating information relative to the problems he was dealing with. In his intercourse with others he was fond of analytical discussion, during which one might be sure of having numerous phases of the subject presented for consideration. To the attentive listener he was full of suggestive ideas, and made a deep impression for his originality of thought.

A National Society of Agriculture has been organized in Egypt, under the patronage of the Khedive, for the promotion of agricultural investigations on seeds, plants, fertilizers, domestic animals, beneficial and injurious insects and birds. The society will have its headquarters at Cairo and will publish a bi-monthly bulletin. It will endeavor to effect exchanges of publications with agricultural societies, experiment stations, and other agricultural organizations in different countries. It will also organize agricultural exhibitions and it is proposed to carry on six experimental farms under its auspices. A large number of the leading farmers of Egypt have been enrolled as members of this society. Its secretary is George P. Foaden, formerly professor of agriculture in the agricultural college at Ghizeh, maintained by the Egyptian Government.

OFFICIAL METHODS OF ANALYSIS OF FERTILIZERS AND
FEEDING STUFFS ADOPTED BY THE BELGIAN STATE
LABORATORIES AND THE AGRICULTURAL
EXPERIMENT STATIONS OF HOLLAND.

The State laboratories of Belgium and the agricultural experiment stations of Holland have recently adopted uniform methods for the analysis of fertilizers and feeding stuffs. While the methods are, as a rule, very similar to the official methods in this country and in Germany, they differ somewhat in the details of execution. The following condensed account of the methods is taken from the bulletin of the Belgian Minister of Agriculture.¹

ANALYSIS OF FERTILIZERS.

Ammoniacal nitrogen.—Ammoniacal nitrogen is determined by distilling 50 cc. of a solution prepared by dissolving 10 gm. of sulphate of ammonia in 1 liter of water with calcined magnesia, the ammonia being collected in 20 cc. of one-half normal sulphuric acid and the excess of acid titrated with alkali, preferably one-fourth normal barium hydrate.

Nitric nitrogen.—For the determination of nitric nitrogen two methods may be employed, the Schloesing-Graudeau and the Ulsch methods. In the first case, with nitrate of soda, 10 cc. of a solution containing 16.5 gm. of the nitrate per liter is used; with nitrate of potash the same amount of a solution containing 20 gm. of the nitrate per liter is used. The solution of nitrate is treated in a Schloesing apparatus with 50 cc. of a solution of ferrous chlorid saturated in the cold and an equal volume of concentrated hydrochloric acid, rinsing the funnel with dilute acid (1 to 1). The results obtained are compared with those obtained by the same treatment of 10 cc. of type solutions containing 33 gm. of pure nitrate of soda or 40 gm. of pure nitrate of potash per liter. The receiver for the gas is filled with cold distilled water recently boiled. Air is expelled from the apparatus by introducing a little nitrate.

The form of Ulsch method used (not applicable in the presence of ammoniacal salts) is as follows: To 25 cc. of a solution prepared by dissolving 10 gm. of the substance in 1 liter of water 5 gm. of iron reduced in hydrogen and 10 cc. of dilute sulphuric acid (1 volume of concentrated acid to 2 volumes of distilled water) are added in a $\frac{1}{2}$ -liter flask, which is connected with a condenser. The solution is heated

¹Bul. Min. Agr. [Belgium], 1898, No. 3, pp. 18.

until evolution of gas commences. The flame is then removed until the evolution subsides. Finally the flask is heated gently for about 5 minutes. One hundred cubic centimeters of distilled water is added and the ammonia distilled off in the presence of 3 gm. of calcined magnesia or of 30 cc. of a soda solution of 1.25 sp. gr.

Organic nitrogen.—Two methods of determining organic nitrogen are employed, the Kjeldahl and the modified Gunning methods. In the first 1 gm. of blood or horn, $1\frac{1}{2}$ gm. of leather, wool, oil cake, or fish guano, and 2 gm. of ground bone is digested with 10 to 20 cc. of sulphuric acid of 66° Baumé, containing 10 per cent of phosphoric anhydrid and a drop of mercury (about 0.5 gm.) or from 0.5 to 1 gm. of mercury bioxid. The digestion is continued at least 1 hour after the solution has become colorless. After cooling the solution is nearly neutralized with potash solution (1 part of potash to 2 of water), and then 40 cc. of a solution containing 50 gm. of caustic soda and 20 gm. of sodium sulphid per liter is added. The operation is continued in the usual way.

In the modified Gunning method the same weights of material are used, the substance being digested in 20 cc. of 66° Baumé sulphuric acid with the addition of 1 gm. of mercury and 1 gm. of copper sulphate. When the substance has become charred 10 to 15 gm. of potassium sulphate in crystals is added and the mixture strongly heated. Digestion is complete in about half an hour. The operation is completed as in the Kjeldahl method.

With fertilizers containing a mixture of nitric and ammoniacal nitrogen 10 gm. is dissolved in 500 cc. of water and 25 or 50 cc. of the solution used for the different determinations, nitric nitrogen being determined by the Schloesing-Grandeau method, ammoniacal nitrogen by distillation with magnesia.

With fertilizers containing organic and ammoniacal nitrogen the total nitrogen is determined in 2 gm. by the Kjeldahl method, ammoniacal nitrogen in 5 gm. by distillation with magnesia.

With fertilizers containing organic and nitric nitrogen the total nitrogen is determined in 1 to 2 gm. by the Kjeldahl-Jodlbauer method as follows: Digest the fertilizer in 20 to 30 cc. of sulpho-phenic acid containing from 60 to 100 gm. of crystallized phenic acid per liter. For hastening solution it is recommended to heat slowly to about 40° C., cool and add 1 gm. of zinc powder in small portions, digest in the cold for at least 2 hours, then proceed as in the ordinary Kjeldahl method. The nitric nitrogen is determined by the Schloesing-Grandeau method.

In fertilizers containing the 3 forms of nitrogen the total nitrogen is determined by the Kjeldahl-Jodlbauer method, ammoniacal nitrogen by distillation with magnesia, and nitric nitrogen by the Schloesing-Grandeau method.

Phosphoric acid soluble in mineral acids.—To 50 gm. of the phosphate add 50 cc. of nitric acid (1.2 sp. gr.) or aqua regia and 50 cc. of water. Boil

for $\frac{1}{2}$ hour, make volume to 500 cc., and filter. In case of substances rich in phosphoric acid, like precipitated phosphate, use 25 cc. of this solution for the subsequent determination; in case of the poorer phosphates, like superphosphates and slags, use 50 cc. Neutralize the greater part of the free acid with ammonia, precipitate in hot solution with 100 cc. of a solution of nitro-molybdate of ammonia, boil, and filter while hot. Wash with 100 cc. of 1 per cent nitric acid. Dissolve in as small amount as possible of ammonia of 0.96 sp. gr. Saturate the larger part of the ammonia with hydrochloric acid and precipitate in the cold with 10 cc. of magnesia mixture, adding 2 or 3 drops of the latter at first and stirring until precipitation commences, then add the rest of the solution at once. Add 50 cc. of strong ammonia (0.96 sp. gr.), allow to stand for 2 hours, filter, wash with 5 per cent ammonia, incinerate, and weigh. Calculate phosphoric acid with the factor 0.64. Substances containing a large amount of organic matter may be dissolved in sulphuric acid, as in the Kjeldahl method. Substances must not be prepared for the determination of phosphoric acid by incineration.

The citro-mechanical method is carried out with 25 cc. of a solution of phosphate, guano, or ground bone, or 100 cc. of a solution of superphosphate made as directed above, the acid being almost neutralized with ammonia, and 30 cc. of Petermann's citrate solution (see below) and 10 cc. of ammonia of 0.91 sp. gr. added. The solution is agitated for $\frac{1}{2}$ hour, during which time 25 cc. of magnesia mixture is added, drop by drop. The precipitate is collected on a filter, washed, incinerated, and weighed.

Phosphoric acid soluble in water and ammonium citrate.—From 1 to 4 gm. of phosphate, according to its content of phosphoric acid, is ground up in a mortar, at first in a dry state, afterwards with 20 to 25 cc. of water, until a uniform mixture is obtained. The solution is decanted on to a filter, the filtrate being collected in a 250 cc. flask. This operation is repeated 3 times, when all of the material is thrown on to the filter and washed until the volume of the filtrate amounts to about 200 cc. A few drops of nitric acid is added if the phosphoric acid is to be precipitated by ammonium nitro-molybdate, or hydrochloric acid if the citro-mechanical method is to be used. The filter with the insoluble residue is placed in a 250 cc. flask with 100 cc. of alkaline ammonium citrate. In case of precipitated phosphates the previous extraction with water is omitted and the material is treated directly with the citrate. The insoluble residue is digested in the ammonium citrate in the cold for 15 hours with stirring, afterwards for 1 hour in a water bath at 40° C. The citrate extract, after cooling, is made up to 250 cc. and filtered. To a mixture of 50 cc. of this solution and 50 cc. of the water solution previously obtained 10 cc. of hydrochloric acid (1.1 sp. gr.) is added and the solution kept at the boiling point for 30 minutes to transform the metaphosphoric acid into orthophosphoric acid. The phosphoric acid is determined either by the molybdic or citro-mechanical method. If the former is used, previous boiling with hydrochloric acid is unnecessary,

Potash—general method.—In the analysis of potash salts 10 gm. of the material is placed in a liter flask with about 500 cc. of water and brought to the boiling point, just enough barium chlorid is added to precipitate the sulphuric acid, the volume made up to 1 liter, and filtered. To 20 cc. of this solution in case of sulphate and 50 cc. in case of kainit 10 cc. of 10 per cent platinum chlorid is added and the solution evaporated to a sirupy consistency. The residue is taken up in 85 per cent alcohol, the crystals carefully broken, the precipitate collected on a tared filter or Gooch crucible, washed with the alcohol, dried at 125° in an air or xylol bath, and weighed. The factor 1.94 is used in calculating potash.

Potash—special methods.—Under this head are described the Netherlands and the Corenwinder and Contamine methods. In the first, which is applicable to superphosphate of potash and mixed fertilizers, 20 gm. of substance is boiled with water for $\frac{1}{2}$ hour, the solution cooled, and made up to 500 cc. To 50 cc. of the filtered solution at the boiling point just enough barium chlorid to precipitate the sulphuric acid is added, followed by the addition of an excess of barium hydrate. The solution is cooled, made up to 100 cc., and filtered. To 50 cc. of the filtrate ammonium carbonate and ammonia are added at the boiling point until no further precipitation occurs. The solution is cooled, made up to 100 cc., and filtered. Fifty cubic centimeters of the filtrate is evaporated and ignited to remove ammonium salts. The residue is taken up in water, filtered, and treated as in the general method.

In the method of Corenwinder and Contamine to 50 cc. of a solution of 10 gm. in 1 liter of water 1 cc. of hydrochloric acid is added and the solution evaporated and ignited just below redness to drive off ammonium salts and organic matter. The residue is taken up in water, acidulated with hydrochloric acid, and the solution evaporated to a sirupy consistency with the addition of 10 cc. of 10 per cent platinum chlorid. The precipitate is washed with 80 per cent alcohol and then redissolved in hot water, the solution being allowed to pass into 50 cc. of 10 per cent sodium formate kept at the boiling point. This solution is heated until reduction is complete and acidulated with hydrochloric acid, a large excess of the latter being carefully avoided. The platinum is collected on a filter, washed with cold water and ignited. The potash is calculated by multiplying the weight of platinum by 0.4835. The reduction may be made by means of mercurous chlorid, according to Mercier, instead of with sodium formate.

The determination of the fineness of mineral phosphates and slays.—Fifty grams of material is shaken up for 30 minutes in a sieve, the meshes of which are 0.17 mm. square, the actual size of the holes being 0.029 mm.

ANALYSIS OF FEEDING STUFFS.

Preparation of samples.—Samples are ground until they pass a sieve with 1 mm. meshes.

Determination of water.—Five grams of material is dried in an air bath at a temperature of from 100 to 105° C. to constant weight.

Determination of ash.—Five grams of the substance is incinerated in a muffle until the ashes are white or light gray. The Belgian law requires that the amount of matter in the ash insoluble in 10 per cent hydrochloric acid shall be determined and that it shall not exceed 2 per cent.

Determination of crude protein.—Nitrogen is determined in 1 to 2 gm. of substance by the Kjeldahl method, the protein being calculated from the nitrogen by the use of the factor 6.25.

Determination of pure albuminoids.—This is done by means of Stutzer's method as follows: To 1 gm. of the substance is added 100 cc. of water and the solution brought to the boiling point, 2 to 3 cc. of a saturated solution of alum is added, and then a quantity of copper hydrate corresponding to about 0.4 gm. of copper oxid. After cooling the residue is collected on a filter, washed at first with water, and afterwards with alcohol. The nitrogen is determined in the filter and contents by the Kjeldahl method without previous drying. The factor 6.25 is used in calculating the albuminoids from the nitrogen thus found. If the substance contains an alkaloid it is first boiled on a sand bath with 100 cc. of alcohol containing 1 cc. of acetic acid. The solution thus obtained is decanted through the same filter, which is afterwards used for collecting the copper hydrate precipitate.

Determination of fat.—For this purpose 3 to 5 gm. of the substance is exhausted in one of the common forms of extractors with carbon tetrachlorid or ether. Commercial ether is redistilled with sodium before use for this purpose, and the sample is dried at 100° C. in the air or in a current of inert gas before extraction with the ether. The extract is collected in 100 to 150 cc. flasks, and after the solvent is driven off, dried for 2 hours at 98 to 100° C. in a hot-water bath and weighed. For the determination of substances other than fat which are dissolved by the ether, the residue is redissolved in ether, an equal volume of alcohol is added, the solution exactly neutralized, and evaporated to dryness. The residue is taken up in ether, filtered into a tared flask, the solvent driven off, and the residue dried for 2 hours and weighed as pure fat.

Determination of crude cellulose.—Three grams of the substance is boiled for $\frac{1}{2}$ hour with 200 cc. of 1.25 per cent sulphuric acid, the liquid being maintained meanwhile at a constant level. After settling, the solution is decanted, and the residue is extracted twice in the same manner with 200 cc. portions of water. The different extracts are collected in one flask. After settling, the supernatant liquid is siphoned off, the residue is combined with that in the digestion flask, and the whole is treated as described above, first with 200 cc. of 1.25 per cent potassium hydrate, and then with 2 successive portions of 200 cc. each of water. The extracts thus obtained are treated as above

described. The residues are washed 2 or 3 times by decantation with boiling water, finally collected on a weighed filter, washed with hot alcohol and with ether, dried at 100° C., and weighed. The ash is determined in the residue thus obtained and its weight deducted in calculating the cellulose.

Cellulose is also determined by means of the Holdefleiss method. In this case 3 gm. of the material and 200 cc. of 1.25 per cent sulphuric acid are placed in a Holdefleiss flask and the solution kept at the boiling point for $\frac{1}{2}$ hour by the injection of steam. The material is collected on an asbestos filter and washed with hot water until the filtrate is no longer acid. The residue is treated in the same manner with 200 cc. of potassium hydrate, the washing being continued in this case until the alkaline reaction disappears. The residue is then washed with alcohol and ether, dried, and weighed. It is then incinerated and weighed again. The difference between the two weights gives the crude cellulose.

PREPARATION OF SPECIAL REAGENTS.

Ammonium nitro-molybdate.—Dissolve 150 gm. of ammonium molybdate in 1 liter of distilled water, pouring the solution into 1 liter of nitric acid of 1.2 sp. gr.

Magnesia mixture.—Dissolve 100 gm. of crystallized magnesium chlorid, 200 gm. of crystallized ammonium chlorid, and 400 gm. of ammonia of 0.96 sp. gr. in water, making the volume up to 1,250 cc., and filter after standing 48 hours.

Alkaline ammonium citrate.—Dissolve 500 gm. of citric acid in just enough ammonia of 0.92 sp. gr. to give a neutral reaction (about 700 cc.). On cooling add water until the specific gravity is 1.09 at 15° C. Add 50 cc. of ammonia of 0.92 sp. gr. to each liter of this solution, stir, let stand for 48 hours, and filter. The specific gravity of the solution thus obtained is from 1.082 to 1.083.

Stutzer's reagent.—Dissolve 100 gm. of crystallized copper sulphate in 5 liters of water, add about 2 gm. of glycerin, and precipitate the cuprous hydrate by adding dilute soda solution until the reaction is faintly alkaline, filter, and diffuse the precipitate in water containing 5 gm. of glycerin per liter. Wash by decantation until the precipitate is free from excess of alkali. The precipitate is finally diffused in water containing glycerin and kept in a dark place in a closely stoppered flask. The amount of copper oxid in the reagent is determined by the evaporation and ignition of 10 cc. of it.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The determination of citrate-soluble phosphoric acid in bone meal, superphosphates, etc., O. BÖTTCHER (*Chem. Ztg.*, 22 (1898), No. 21, pp. 201, 202).—Five grams of the substance is rubbed fine with a dilute acid ammonium citrate solution (1 volume of the concentrated solution mixed with 4 volumes of water), washed into a 500 cc. flask, which is then filled to the mark with the dilute acid citrate solution at the room temperature (about 17.5° C.). The flask is then closed with a rubber stopper and kept for 30 minutes in a rotating apparatus which revolves 30 or 40 times per minute. The mixture is now filtered and suitable portions of the liquid taken for the determination of phosphoric acid, either by the molybdate or the citrate method.—J. T. ANDERSON.

A contribution to the determination of potash, J. DIAMANT (*Chem. Ztg.*, 22 (1898), No. 12, p. 99).—The method proposed involves the reduction of potassium-platinum chlorid by means of zinc dust, and the volumetric determination of chlorine in the liquid residue. About 0.5 gm. of potassium-platinum chlorid (the amount taken of the potash compound to be analyzed being such as to yield about that amount of the double salt) is collected on a filter and washed in the usual way. It is then dissolved in hot water in a 500 cc. flask and the volume made to the mark with cold water. It is now shaken with about 1 gm. of zinc dust, when reduction begins instantly. When the color disappears, showing that reduction is complete, the liquid is filtered through a dry filter, and 250 cc. of it is used for the volumetric determination of chlorine.—J. T. ANDERSON.

A new method of determining fat in feeding stuffs, meat, feces, etc., L. LIEBERMANN and S. SZÉKELY (*Arch. Physiol.* [*Pflüger*], 72 (1898), No. 7-8, pp. 360-366, fig. 1).—The author describes in detail a method of determining fat as follows: Boil for half an hour 5 gm. of substance with 30 cc. of 50 per cent potassium hydroxid solution (sp. gr. 1.54), over a free flame, shaking frequently. This should be done in a flask of suitable shape which when filled to about the middle of the neck will contain about 290 cc., and has a mark at 240 cc. When cool add 30 cc. of 90 to 94 per cent alcohol and warm for about 10 minutes, then cool and add carefully, in small portions, 100 cc. of 20 per

cent sulphuric acid (sp. gr. 1.145), shaking frequently and cooling to prevent the loss of volatile fatty acids. The solution should contain an excess of about 4.4 gm. sulphuric acid. When the solution is quite clear add 50 cc. petroleum ether of good quality (sp. gr. 0.6 to 0.7, boiling point about 60°), close the flask tightly and shake thoroughly 30 times at intervals of 1 to 2 minutes. The cork should not be removed, since some of the petroleum ether would evaporate. Add sufficient saturated sodium chlorid solution to make 290 cc., shake a few times, and allow the flask to stand a short time in a cool place. The bottom of the petroleum ether layer should be at the 240 cc. mark on the neck of the flask. The petroleum ether will contain all the fatty acids in solution. Remove 20 cc. with a suitable pipette, dilute with 40 cc. of 96 per cent alcohol, add 1 cc. of phenolphthalein and titrate with an alcoholic solution of decinormal potassium hydroxid, noting the amount required. Evaporate in a suitable vessel with a glass cover upon a moderately warm water bath or in other convenient way, dry at 100° C. and weigh with the cover on the dish, since the potassium salts of fatty acids are hygroscopic.

The amount of fat in the original material can be calculated with the aid of the following formula:

$$F = \left[\frac{S - 0.01 - (K \times 0.00255)}{A} \right] 0.250.$$

F equals fat in original substance, S the weight of potassium salts of fatty acid in 20 cc. of petroleum ether, K the amount of potassium hydroxid solution used, and A the weight of the material taken.

Modifications of the method are given for use in determining the amount of fat in hay, flour, and grain, and comparisons of this method with the Soxhlet method of extraction. The results show that the method is accurate, and in the authors' opinion it can be recommended as being more rapid than the ordinary methods.

Determinations of fat by Liebermann's saponification method, F. TANGL and J. WEISER (*Arch. Physiol. [Pflüger]*, 72 (1898), No. 7-8, pp. 367-369).—The authors determined the fat in a number of samples of meat and feces by the method described above and by Dormeyer's method (*E. S. R.*, 7, p. 919). Equally good results were obtained in both cases. The first method is recommended as fully as accurate as Dormeyer's and less time consuming.

A simple method for the estimation of carbohydrates (sugar, starch, dextrin) in foods and condiments, F. GROMMES (*Sitzungsber. Phys.-med. Soc. Erlangen*, 29 (1897), pp. 17-28, fig. 1).—The author describes Fleischer's apparatus and method for determining the sugar content of foods and beverages. The apparatus is shown in the accompanying figure (fig. 9). The method for determining sugar in wine, beer, and other liquids is as follows: A sample of the liquid, decolorized with animal charcoal (if this is necessary), is boiled with

potassium hydroxid or sodium hydroxid solution to determine something of the amount of sugar which it contains and how much it is desirable to dilute the material before estimating the sugar. If a deep brown color is obtained the wine, beer, or liquid should be much diluted. If the color is faint less dilution is necessary. After diluting a known quantity of the material, yeast is added and it is placed in the Fleischer apparatus, the apparatus tightly closed and allowed to remain in a warm place for 24 hours. The carbon dioxide produced causes the column of mercury (1) to rise in the graduated tube. The amount of sugar is calculated by making a control experiment under the same conditions with a solution containing a known amount of dextrose.

FIG. 9.—Fleischer's apparatus.

In case of vegetables, etc., the finely divided material is extracted with water until a qualitative test shows that sugar is no longer obtained. The sugar in the aqueous extract is then determined as above.

In case of flour, bread, and similar materials the starch was also determined. The material, carefully dried, was inverted by boiling with dilute hydrochloric acid and the total dextrose determined as above. The difference between this result and the sugar in the original substance showed the dextrose derived from starch. The starch could then be calculated.

The author reports the results of numerous determinations, some of which are shown in the following table:

Sugar and starch in a number of food materials.

	Sugar.	Starch.
	<i>Per cent.</i>	<i>Per cent.</i>
Potatoes, raw	2.876-2.634
Potatoes, cooked	2.037-1.873
Carrots	7.210
Orange peel	14.570
Lemon peel	18.960
Lemon without peel	3.133
Orange without peel	24.640-22.976
Pears	14.259-16.375
Apples	12.153-14.919
Plums	4.170
Dates	64.270-58.840
Rye flour	1.885	60.76
Wheat meal (Gries mehl)	2.500	63.45
Wheat flour	3.820	65.36
Barley flour	5.450	59.16
Oatmeal	3.76	63.52
Corn meal	4.29	60.92
Kommiss bread	1.758	a 46.36
Graham bread	1.805	a 21.76
Black bread	2.514	a 45.33
White bread	2.538	c 48.69
Roman bread	3.224	a 42.93
"Erlangen kipt" bread	3.696	a 54.29
Pumpernickel	13.559	a 41.87
Tea cakes	4.532	a 38.64
Almond bread	1.494	a 8.51

a Starch and dextrin.

The sugar content of different food materials is discussed in relation to the diet of patients suffering from diabetes.

A new method for drying feces, H. PODA (*Ztschr. Physiol. Chem.*, 25 (1898), No. 3-4, pp. 354-359).—The author proposes to simplify the drying of feces for analysis by adding absolute alcohol, which assists in driving off the water. The fresh material is dried in a porcelain dish on a water bath for from 4 to 6 hours, at the end of which time it is usually solid when cooled. It is then mixed in the same dish with 50 cc. of absolute alcohol, being broken up into small pieces, and dried on the water bath for about an hour, when the operation is repeated with 25 cc. of alcohol. It is then usually dry enough so that it can be ground in the dish to a fine powder, but if not it is treated again with 25 cc. of alcohol and dried. The material, which contains from 2 to 5 per cent of water, is placed in portions of 2 or 3 gm. in beakers and dried in an air bath at 99 to 100°.

A table is given showing the time required for drying feces with and without treatment with alcohol. The author concludes that the method is a simplification of the ordinarily tedious process, being more rapid and requiring less attention, and giving more accurate results.

The albuminoids, P. NOLF (*Ann. Inst. Pasteur*, 12 (1898), No. 7, pp. 471-480; 8, pp. 547-560).—A critical review of the subject.

Concerning the constitution of the simplest albuminoids, A. KOSSEL (*Ztschr. Physiol. Chem.*, 25 (1898), No. 3-4, pp. 165-189).—This deals with the "protamins" elupein, salmin, and sturin, their constitution, decomposition products, relation to albuminoid bodies, etc.

The cleavage of crystalline egg and serum albumin and of serum globulin by pepsin digestion, F. UMBER (*Ztschr. Physiol. Chem.*, 25 (1898), No. 3-4, pp. 258-282).—The method of work and the characteristics of the different fractions obtained from each of these albuminoids are described.

The cleavage products of the proteids prepared from conifer seeds, E. SCHULZE (*Ztschr. Physiol. Chem.*, 25 (1898), No. 3-4, pp. 360-362).—A continuation of a former paper.

Inversion of sugar by neutral salts in the presence of glucose, H. C. PRINSEN-GEERLIGS (*Ztschr. Spiritusind.*, 21 (1898), No. 30, p. 266).

The chemistry of chlorophyll, L. MARCHLEWSKI (*Jour. Prakt. Chem.*, n. ser., 57 (1898), p. 330).

A review of Marchlewski's contribution on the chemistry of chlorophyll, G. BODE (*Jour. Prakt. Chem.*, n. ser., 57 (1898), pp. 488-493).

Report of the committee of the agricultural experiment stations and laboratories on the methods of analysis of fertilizers (*Bul. [Min. Agr. France]*, 16 (1897), No. 2, pp. 219-251).—This report deals with the following topics:

Preliminary examination of fertilizers, including qualitative tests for potash, phosphoric acid, ammonia, nitric acid, and organic nitrogen; the sampling of fertilizers, including the taking of samples and their preparation in the laboratory; the determination of potash in muriate, sulphate, and complex forms of potash by

means of perchloric acid according to Schloesing, in the form of double chlorid of platinum potassium, and by the method of Corenwinder and Contamine (E. S. R., 9, p. 416); the determination of nitrogen in different forms, including organic nitrogen by means of soda lime in fertilizers rich and poor in nitrogen but containing no nitrates, by the method of Grandeau in substances which are difficult to mix and pulverize, in all three forms in a mixed fertilizer, and by the Kjeldahl method, ammonia in ammonium sulphate by the Schloesing apparatus, ammonia in a complex fertilizer, and nitric acid in nitrates by the Schloesing method; the determination of phosphoric acid in different forms, including natural phosphates of lime, precipitated phosphates, guanos, poudrettes, etc.; the determination of phosphoric acid by the molybdic method, of soluble phosphoric acid in superphosphates and chemical fertilizers, phosphoric acid in sulphuric acid solutions, the degree of fineness of phosphates, and the examination of phosphatic slags.

Gladding's method for phosphoric acid, J. B. COFFOCK (*Chem. News*, 77 (1898), No. 2009, p. 242).—This is a comparison of the magnesia and Gladding's methods on boiled bones and superphosphates. In the tests made there was a very satisfactory agreement between the results obtained by the two methods. Although somewhat higher percentages were obtained by the Gladding method, the author concludes that the Gladding method is reliable enough for fertilizer work and has the advantage of being very rapid.

Determination of phosphorus in steel, iron, and iron ores, J. OHLY (*Chem. News*, 76 (1897), No. 1978, p. 200).

Volumetric estimation of combined sulphuric acid, F. TELLE (*Jour. Pharm. et Chim.*, 6. ser., 7 (1898), No. 4, p. 165).—The sulphuric acid is precipitated with barium chlorid after acidulating with hydrochloric acid; the excess of baryta is precipitated with potassium bichromate, and finally the excess of chromate is estimated, by the iodine displaced, by sodium thiosulphate.—B. H. HITE.

On Fehling's solution, O. ROSENHEIM and P. SCHIDROWITZ (*Chem. News*, 76 (1897), No. 1988, p. 318; 1897, p. 97).—A reply to a paper by Jovitschitsch² and Siegfried.³ The authors maintain that alkali salts of mineral acids (hydrochloric, nitric, and sulphuric) do not possess the property of reducing Fehling's solution.—B. H. HITE.

A quick polarimetric method for the estimation of starch in flour, etc., E. DOWZARD (*Chem. News*, 77 (1898), No. 1998, p. 167).—One gram of the flour is mixed with a little cold water, 35 cc. of boiling water added, the mucilage kept at 100° for $\frac{1}{2}$ minute, cooled to 48°, and treated with 20 cc. of a 10 per cent malt-extract solution that has been shaken with kaolin and filtered. The mixture is kept at 48° for 20 minutes, brought just to boiling, and filtered. The cooled filtrate is made up to 100 cc., a small quantity of kaolin added, filtered again, and the optical rotation taken in a 20 cm. tube. The optical rotation of the malt-extract solution and of the dextrin in the flour must be deducted.—B. H. HITE.

The estimation of carbohydrates (sugar, starch, and dextrin) in foods and condiments by a simple method, F. GROMMES (*Die Bestimmung der Kohlenhydrate (Zucker, Stärke, Dextrin) in beliebigen Nahrungs- und Genussmitteln vermittels einer leicht ausführbaren Methode*. Inaug. Diss., Erlangen, 1897, pp. 178; abs. in *Hyg. Rundschau*, 8 (1898), No. 11, pp. 550, 551).—This is a full account of work reported above (p. 311).

Zinc in water, P. A. E. RICHARDS (*Chem. News*, 76 (1897), No. 1986, p. 293).

Introduction to the micro-chemical analyses of the most important organic compounds, BEHRENS (*Anleitung zur mikrochemischen Analyse der wichtigsten organischen Verbindungen. Hamburg and Leipzig: L. Voss, 1897, pt. 4, pp. 138, figs. 91; rev. in Centbl. Bakt. u. Par., 1. Abt., 24 (1898), No. 2-3, p. 101*).

A new asbestos filter tube, A. GOSKE (*Chem. Ztg.*, 22 (1898), No. 4, p. 21, fig. 1).—A conical stricture is made in a combustion tube, and into this stricture a small hollow perforated ball is fitted. The asbestos is lightly packed around and over this ball.—J. T. ANDERSON.

A new filter apparatus with a two-way cock and attached arms running out on two sides (*Chem. Ztg.*, 22 (1898), No. 6, p. 39, fig. 1).—Especially useful in cases where precipitates are to be washed with 2 liquids in succession and it is desired to collect the wash liquids separately. The 2 arms of the apparatus are connected with separate receptacles, and by turning the stopcock properly the liquid from the funnel may be made to flow into the one or the other at pleasure.—J. T. ANDERSON.

A practical filter stand, H. FABER (*Chem. Ztg.*, 22 (1898), No. 6, pp. 39, 40, fig. 1).—Two circular discs of unequal diameters are securely fastened together at a fixed distance apart, one over the other, and so supported on a vertical axis that they may revolve together around it. The upper disc is the smaller and has a circle of holes near the rim at suitable distances apart to hold the funnels. The filter glasses and the beakers both rest below on the other disc. A slight modification is suggested by which the smaller disc is made of adjustable height above the lower. Economy of space on the work table is the advantage claimed for this stand.—J. T. ANDERSON.

An easily constructed apparatus for fractional distillation in vacuo, R. L. STEINLIN (*Chem. Ztg.*, 22 (1898), No. 18, pp. 157, 158, figs. 2).

An efficient gas-pressure regulator, P. MURKILL (*Jour. Appl. Micros.*, 1 (1898), No. 5, pp. 92-94, figs. 4).

On the reaction of filter paper, L. MAGNIER (*Jour. Pharm. et Chim.*, 6, ser., 6 (1897), No. 10, p. 438).—The statement is made that filter papers always retain a small quantity of acid, no matter how well they are washed with cold water. Prolonged washing with boiling water removes the last traces of acid.—B. H. HITE.

Chemical department, E. F. LADD (*North Dakota Sta. Rpt. 1897, pp. 9-16*).—A summary of the work of this department of the station during the year, including a summary of observations on temperature and rainfall; analyses of 9 samples of soil, 7 of baking powders, and 4 of corn fodder, with notes on the examination of well waters and on sugar beets grown in different parts of the State.

Report of the chemist, W. R. PERKINS (*Mississippi Sta. Rpt. 1897, pp. 8-10*).—This is a brief account of the work of the year in this department of the station, including a note on the soil work which has been undertaken by the station, analyses (mineral constituents) of 4 samples of artesian water, determinations of nitrogen in rainfall 1894-1897, and a statement of miscellaneous chemical work.

BOTANY.

Review of the investigations of the grain rust, J. ERIKSSON (*Per. Andra Nord. Landtbr. Kongr., Stockholm, 1897, I, pp. 91-109; also Bot. Gaz., 25 (1898), No. 1, pp. 26-38, and Rer. Gén. Bot., 10 (1898), No. 110, pp. 33-48, fig. 1*).—The paper gives the main results of the investigations of the grain rust conducted by the author since 1890 at the State agricultural experiment station at Albano, Sweden. The conclusions to which the results have led are summarized as follows:

The fungi which cause rust disease in the cereals are at least 10 in number, partly species, partly specialized forms of species, and the spreading of disease between different grain crops and grasses is thereby materially restricted. Prior to 1890 the recognized species of grain rust fungi were the common grain rust, *Puccinia graminis*, the æcidial form of which was *Æcidium berberidis*; smaller grain rust, *P. rubigo-vera*, æcidial form *Æ. asperifolii*; and crown rust, *P. coronata*, æcidial form *Æ. rhamni*. The author recognizes 8 species, having divided them as follows: *P. graminis* into (1) *P. graminis* and (2) *P. phlei-pratensis*; *P. rubigo-vera* into (3) *P. glumarum*, (4) *P. dispersa*, and (5) *P. simplex*; and *P. coronata* into (6) *P. coronifera*, (7) *P. coronata*, and (8) an unnamed species. Each of these is considered to have developed specialized forms as follows:

(1) *P. graminis*, black rust, *Æcidium berberidis*.—Forms (a) *secalis* on *Secale cereale*, *Hordeum vulgare*, *H. jubatum*, *Triticum caninum*, *T. desertorum*, *T. repens*, *Elymus arenarius*, and *Bromus secalinus*; (b) *arvenæ* on *Avena sativa*, *A. elatior*, *A. sterilis*, *Dactylis glomerata*, *Alopecurus pratensis*, *Milium effusum*, *Lamarkia aurea*, and *Trisetum distichophyllum*; (c) *tritici* on *Triticum vulgare*; (d) *airæ* on *Aira cæspitosa*; (e) *agrostidis* on *Agrostis canina*, *A. stolonifera*, and *A. vulgaris*; and (f) *poæ* on *Poa compressa* and *P. cæsia*.

(2) *P. phlei-pratensis*, timothy rust, on *Phleum pratense* and *Festuca elatior*, æcidium unknown.

(3) *P. glumarum*, yellow rust.—Forms (a) *tritici* on *Triticum vulgare*, (b) *secalis* on *Secale cereale*, (c) *hordei* on *Hordeum vulgare*, (d) *elymi* on *Elymus arenarius*, and (e) *agropyri* on *Triticum repens*, æcidium unknown.

(4) *P. dispersa*, brown rust, *Æcidium auchusa*.—Forms (a) *secalis* on *Secale cereale*, (b) *tritici* on *Triticum vulgare*, (c) *agropyri* on *T. repens*, and (d) *bromi* on *Bromus arvensis* and *B. briziformis*.

(5) *P. simplex*, dwarf rust, on *Hordeum vulgare*, æcidium unknown.

(6) *P. coronifera*, crown rust, *Æcidium cathartica*.—Forms (a) *arvenæ* on *Avena sativa*, (b) *alopecuri* on *Alopecurus pratensis* and *A. nigricans*, (c) *festuæ* on *Festuca elatior*, (d) *lolii* on *Lolium perenne*, (e) *glyceriæ* on *Glyceria aquatica*, (f) *holci* on *Holcus lanatus* and *H. mollis*.

(7) *P. coronata*, crown rust, *Æcidium frangulae*.—Forms (a) *calamagrostis* on *Calamagrostis arundinacea* and *C. lanceolata*, (b) *phalaridis*

on *Phalaris arundinacea*, (c) *agrostidis* on *Agrostis vulgaris* and *A. stolonifera*, (d) *agropyri* on *Triticum repens*, and (e) *holci* on *Holcus lanatus* and *H. mollis*.

(8) Species undescribed.—Forms (a) *epigaei* on *Calamagrostis epigeios* and (b) *melicæ* on *Melica nutans*.

In addition studies not yet completed have shown that besides the black rust of the 23 grasses given, the rusts found on the following species of grasses have been found to be true forms of black rust: *Aira flexuosa*, *Alopecurus nigricans*, *Elymus glaucifolius*, *Panicum miliaceum*, *Phleum boehmeri*, *P. michclii*, *Poa chairii*, *P. pratensis*, and *Triticum unicum*.

Spreading of rust is often insignificant (1) between small grains and grasses that may carry the same specialized fungus forms; (2) from and to the plant species carrying winter rust in case such form is found; and (3) occasionally between different cultural forms of the same grain species.

The viability of summer and winter rust spores is in many cases small or at least uncertain.

The spreading of the rust depends to a large extent on the distance. In a circular recently issued by the Swedish Agricultural Department it is ordered that no barberry, whether wild or planted, be allowed to grow at a distance less than 25 to 50 meters (82 to 164 ft.) from grain fields.

The viability of the winter spores is dependent on certain exterior conditions (moisture, temperature, etc.) and is limited to a short time.

The yellow rust appears on certain particularly susceptible kinds of wheat and barley 4 to 5 weeks after sowing.

The intensity of the yellow rust has sometimes proved greater on open than on shaded parts of the same field.

Shoots of wheat which early in the spring were enclosed in wide glass tubes closed at both ends with cotton, developed stalks which were rusty after 6 to 8 weeks. In the same way barley plants of a kind easily attacked by yellow rust, grown in sterilized soil and protected against contagion from without during the entire growing period, have in certain cases after 6 to 8 weeks become infected with yellow rust.

The fungus lives for a long time a latent life in the cells of the germ, and shortly before the appearance of rust spots, in the presence of favorable outer conditions changes to a visible mycelium.

The general conclusion is therefore drawn that the appearance of the grain-rust disease depends primarily upon a disease germ present in the plant itself, which in certain cases is inherited from the mother plant in the seed grain and lives there, as well as in the plant grown from the seed, a latent life as "mycoplasma;" and, secondarily, on infection from without from diseased neighbors. The intensity of the disease depends (1) on the energy with which prevailing external con-

ditions (weather, soil, manuring, etc.) are able to bring the disease germ from the latent stage to the visible mycelium and (2) on the supply of new infectious material from without.—F. W. WOLL.

The micro-organisms of the tubercles on the roots of leguminous plants, M. MAZÉ (*Ann. Inst. Pasteur*, 12 (1898), No. 1, pp. 1-25; 2, pp. 128-155, pls. 2, fig. 1).—The author reports an extended investigation of the physiology and morphology of the organism which causes the development of tubercles on the roots of leguminous plants and through which the assimilation of atmospheric nitrogen takes place.

In his general conclusions he states that the free micro-organisms in the soil are attracted toward the roots of leguminous plants by the intervention of carbohydrates diffused in the soil in the vicinity of the root hairs. The organisms penetrate the tissues and cause the formation of a meristematic growth which gives rise to the tubercles. Before the tubercles are formed the organisms are engulfed in a glutinous body which has somewhat the aspect of a mycelium. Later, by the circulation of the sap of the plant into the tubercles, this glutinous material is carried throughout all parts of the plant, and the bacteria are also exposed to the action of the acids dissolved in the plant juices. The pseudo-mycelium does not constitute a part of the living organism. Investigation has failed to show the presence of the organism in this mycelium by any of the means adopted. By the time the plant is matured the tubercles are deprived of their nutrition and the bacteria issue from the tubercles in the form of a bacillus endowed with new properties and capable of living free in the soil.

The fixation of free nitrogen can be brought about in artificial cultures as well as in the root tubercles. The author found that the addition of saccharose to various culture media and the thorough aeration of the medium admitted a growth of the organism that was capable of fixing the free nitrogen. The proportion between the amount of nitrogen fixed and the saccharose furnished to the organism was somewhat constant. When 2 per cent was added to the medium, a little more than double the amount of nitrogen was fixed than when only 1 per cent was used. All the forms which are found in nature may be reproduced in artificial media by the action of heat, acid, peptonized media, etc.

The bacteria recently isolated from the tubercles retain for some time their ability to reproduce new tubercles by inoculation. The forms differentiated during the saprophytic life are gradually lost. The author states that the saprophytic forms in the soil are undoubtedly able to establish themselves on roots and form tubercles, but that he has so far been unable to isolate them from the soil. The independent forms of the root tubercle organism are said to represent a state of dissociation; the first a bacterium which bears endogenous spores; the other an Oospora which bears conidia. The last state is usually borne upon the surface of the soil. The bacteria spread during the winter

and the Oospora form is met with toward the end of the summer. The author states that this method of development will be found to occur frequently among lower organisms and that it will apply to a great number of plants and lower animals.

The micro-organisms of the Leguminosae are in many cases pathogenic to certain animals.

Notes on the salt-marsh plants of northern Kansas, J. H. SCHAFFNER (*Bot. Gaz.*, 25 (1898), No. 1, pp. 255-260).—The author reports upon studies of the vegetation of the salt marshes and springs, which are said to be quite common in central Kansas. The particular region reported upon was visited in August, 1897, and consists of a marsh about 7 miles long, which varies from a quarter of a mile to a mile in width. The conditions in the vicinity of this marsh are said to be quite natural, no cultivation having been attempted near it. Another region was visited the same season and some notes relative to the flora of this marsh are appended.

The author's summary relative to the flora of these salt marshes is as follows:

“(1) The salt marshes of northern Kansas are characterized by large areas absolutely destitute of vegetation; by the paucity of species around their margins; and by the entire absence of all woody plants.

“(2) The vegetation of the streams flowing through them consists of diatoms and the three sedges, *Scirpus pungens*, *S. campestris*, and *S. lacustris*.

“(3) The three characteristic plants in and about the barren portion are *Distichlis maritima*, *Polygonum ramosissimum*, and *Suaeda diffusa*, of which the *Suaeda* is by far the least abundant.

“(4) The plants which may be regarded as successful invaders are the following: *Iva ciliata*, *Sporobolus heterolepis*, *S. texanus*, *Atriplex expansa*, *Aster multiflorus*, *Ambrosia psilostachya*, and *Hordeum jubatum*. *Sporobolus texanus* has never been reported, I believe, beyond the southern part of Kansas. Its abundance in the northern tier of counties of Kansas extends its northern limit nearly 200 miles.

“(5) Among the less successful invaders which are quite common are the following: *Panicum crus-galli*, *P. virgatum*, *Euphorbia marginata*, *E. glyptosperma*, *Chenopodium hybridum*, *Polygonum persicaria*, *P. hydropiper*, *Amarantus chlorostachys*, *Datura stramonium*, *Solanum rostratum*, *Nantheum strumarium*, *Helianthus annuus*, *Eurothera biennis*, *Gaura parviflora*, *Elymus virginicus*, and *Spartina cynosuroides*.”

Investigations on the root development of some forage plants, C. C. GEORGESON and J. E. PAYNE (*Kansas Sta. Bul.* 75, pp. 212-222, pls. 6).—The various plants whose root systems were investigated were the black-eye cowpea, soy bean, Canada field pea, peanut, alfalfa, common millet, Hungarian millet, German millet, African millet, sorghum, pearl millet, Jerusalem corn, white and yellow millo maize, red and white Kafir corn, brown durra, several varieties of field corn, oats, grasses, and sunflower. The soil was dug and washed away from the roots, and their lateral and vertical penetration was measured. The distribution of the roots in the soil as ascertained by the investigation is indicated in the plates in such way as to show the relative root and top development. The widest lateral penetration of any of these roots

was 7 ft. in the case of the cowpea, and the deepest penetration was 6 ft. in the case of one of the varieties of corn.

The authors have conducted an experiment to ascertain the effect of different depths of planting on the development and secondary roots of corn. The corn was planted in pots $\frac{1}{2}$, 1, 2, 3, 4, 5, 6, and 7 in. below the surface. After the plants had grown for 30 days all were taken from the pots and examined, and it was found that the first whorl of secondary roots originated approximately at the same distance beneath the surface of the soil in all cases. The effect of deep and shallow cultivation on the position and development of corn roots was investigated, and it was found that there was but little difference in the depth to which the roots penetrated. Nearly all the plants examined for depth of root development sent their roots down 4 or more feet. The lateral spread of the roots was found to be influenced very materially by the depth of cultivation and method of planting.

The effect of subsoiling on root development of corn was investigated in a limited way. Plants grown on subsoiled plats showed a somewhat greater penetration than those on plats not subsoiled.

The authors, from the work done, do not feel justified in drawing any general conclusions, and merely make a record of the facts as observed and express the hope that the work may serve to induce others to investigate the root development of plants.

Report of the botanical department, H. L. BOLLEY (*North Dakota Sta. Rpt. 1897*, pp. 27-29).—The author briefly reviews the work of his department, stating that the investigations have been confined largely to the principles of culture of field crops and the study of diseases of crops. Some attention has been given to the native plants, and a considerable addition to the herbarium is reported. Bacteriological investigations have occupied a portion of the author's time.

Culture tests of *Tricholoma nudum*, J. COSTANTIN and L. MATRUCHOT (*Compt. Rend. Acad. Sci. Paris, 126 (1898), No. 11, pp. 853-856*).

On impregnating the woody fiber of living trees with coloring solutions, I. SNEVIRYEV (*Trudi Imp. St. Petersburg Obstchestra Yestystroispitatelyei, 25; abs. in Selsk. Khoz. i Lyesor., 187 (1897), p. 240*).—Among other things the author notes the importance of finding a substance which can be introduced into living plants in sufficient quantity to destroy parasites without injuring the plants. A method was discovered by which desired quantities of solutions could be introduced into the roots without injuring the plants, but to find a substance which will destroy parasites when so introduced will require further investigation.—P. FIREMAN.

An investigation concerning the assimilation of free nitrogen by algæ, P. KOSOVICH (*Trudi Imp. St. Petersburg Obstchestra Yestystroispitatelyei, 26; abs. in Selsk. Khoz. i Lyesor., 186 (1897), pp. 237, 238*).—The author concludes that the lower algæ can not assimilate free nitrogen and that the observed increase in the nitrogen content of the soil covered with algæ and nonchlorophyl-bearing organisms is due to some of the latter.—P. FIREMAN.

FERMENTATION—BACTERIOLOGY.

Report of the agricultural-bacteriological laboratory, 1896, A. THEOKTISTOV (*Selsk. Khoz. i Lyesor*, 185 (1897), Jan., pp. 1-1).—The work of the Government laboratory during the year 1896 was confined mainly to studies of cultures of bacilli which kill field mice. Preparations were completed for field experiments in the destruction of marmots (*Spermophilus fulvus*) through the agency of bacteria. Four species of bacteria were studied both microscopically and biologically. The investigation is to be published in detail later. The number of shipments of these bacteria cultures to correspondents and the amount of culture shipped is noted. Experiments were also made to determine whether the disease caused by these bacteria is transmitted by means of the excrement of diseased mice. It was found that the disease was readily transmitted in this way. A more complete account of the results is to be given later.—P. FIREMAN.

ZOOLOGY.

The economic status of the mole, H. WILSON (*Pennsylvania Dept. Agr. Bul. 31, pp. 12, figs. 12*).—The bulletin contains a study of the life history, habits, etc., of the species of the mole family indigenous to Pennsylvania (*Scalops aquaticus*, *S. breweri*, and *Condylura cristata*), the economic relation of this family of mammalia to agriculture; and a tabulated statement intended to show the distribution of the mole throughout the State, this latter information being derived from correspondence.

The stomachs of 36 moles were examined. The data furnished by this examination show that the mole does not take vegetable matter into its stomach intentionally as food. The author believes that his conclusion that the mole is an insectivorous animal is substantiated by the dentation. The mole has abundant opportunity to obtain vegetable food, but with the exception of small quantities of such material it apparently subsists on insects and worms, which are more difficult to obtain.

“Its peculiar habit of burrowing among the roots of grasses and other plants, where it must often seize quickly prey liable to escape, will account satisfactorily for the presence of small fragments of vegetable tissue in its stomach.

“My conclusion, in final, is that, proving the mole to be an ‘insectivorous’ mammalian, is likewise proving its life work to be beneficial to the agriculturists, since of the vast amount of insect life taken as food by the mole, the larger part of it consists of insects whose whole existence is deleterious to plant life, they being vegetation eaters and destroyers; and that the annoyance caused by the mole by its burrowing under and disturbing the roots of growing plants while in quest of food is more than compensated by its destroying and removing therefrom the insect life feeding upon the vitality of these plants.”

The author believes that the damage caused by the eating of grain seeds and fibrous roots, and the gnawing of roots of a tuberous nature, is due to the ravages of the mouse family (*Arvicolinæ*).

“As a matter of fact, the runways of the mole are taken possession of and occupied during the latter part of the summer and autumn season by the common brown ‘field’ or ‘meadow’ mouse (*Arvicola riparia*).

“This mouse, which undoubtedly does the most extensive damage to vegetation of any of our mammalia (being not only granivorous but herbivorous), makes its nest during the early part of the warm season on the surface of the ground in the middle of a luxuriant bunch of grass or other vegetation of a close and dense nature, from which home it makes its runways or paths in all directions (cutting and eating the vegetation clear for a width of from 1.5 to 2 in. in order to make these paths). When the vegetation is taken from the fields during the harvesting of crops, or so closely cropped by the grazing of the cattle as to offer but scanty hiding places from its natural enemies (the hawk and the owl, the fox and the skunk), this mouse takes up its habitation under brush piles, ‘worm’ fences, and rocks, or in stone piles and the underground runways of the mole. The latter it somewhat modifies for its own use and convenience by cutting openings therinto every 2 or 3 ft. of length. The mouse, having thus become domiciled, follows the runways in all their ramifications, and as the mole in its search for food has driven these underground passages to those places where insect life is most prolific, amidst the densest vegetation, so the mouse, following thereafter, has supplied, with little trouble to itself, the vegetable food it so desires.”

Although the author does not believe that moles cause damage by eating vegetable food, yet the fact is recognized that much annoyance may be caused by their "works" in lawns, flower beds, etc. A number of means of exterminating moles are mentioned. These include trapping, poisoning, and driving them away by placing such substances as mineral pitch, gas tar, or other materials of an unpleasant odor in their runways.

The distribution of moles in Pennsylvania is shown in some detail in tabular form.

Are vegetable substances found in the stomachs of moles? V. VRADJ (*Selsk. Khoz. i Lyesor.*, 186 (1897), Aug., pp. 415-430).—Contrary to the generally accepted view that moles feed exclusively on animal substances, the author found substances of vegetable origin in 17 out of 42 stomachs investigated.—P. FREEMAN.

Ornithology of North Carolina, J. W. P. SMITHWICK (*North Carolina Sta. Bul.* 144, pp. 195-228, map 1).—This is a list of the birds of North Carolina with notes on each species. The species listed number 303 and there are 22 which the author says should occur in the State since they are found in neighboring States.

Life zones in New Mexico, T. D. A. COCKERELL (*New Mexico Sta. Bul.* 24, pp. 44).—The bulletin aims to give a broad outline of the subject of the New Mexico life zones, with some illustrative details, fuller data to be published later. The main life zones recognized in New Mexico are the Treeless Zone, above the timber line; the Black Timber Zone, from about 10,000 feet elevation to the timber line; the Mid-alpine Zone, from about 8,000 to 10,000 feet elevation; and the Transition Zone, about 7,000 feet elevation.

Some notes on Nebraska birds, L. BRUNER (*Nebraska Hort. Soc. Rpt.* 1896, pp. 48-179, figs. 51).—The paper gives some general remarks on birds, the text of the Nebraska bird law, and a list of Nebraska birds, together with notes on their abundance, migrations, breeding, food habits, etc. Of the 780 species of North American birds 115 are recorded as visiting Nebraska, 227 as breeding and 100 as wintering in the State.

Report of the State zoologist, B. H. WARREN (*Pennsylvania Dept. of Agr. Bul.* 34, pp. 83-90).—Among other things it is noted that many of the birds and other animals for which bounties are offered are species that subsist largely on detrimental forms of animal life. The plan of offering bounties is not countenanced.

Investigations of the stomach of the English sparrow prove beyond all doubt that it feeds upon cereals, ripe fruits, and buds and blossoms of shade and fruit trees, and that the tender growth of the grape and other vines are especially attacked. It also destroys the young and the eggs of valuable insectivorous birds. Papers are noted on ravens, crows, jays, and shrikes, on skunks and their economic value, household pests, interesting facts concerning game, and miscellaneous natural history notes.

Report of the Commissioner [of Fish and Fisheries], 1896 (*U. S. Com. Fish and Fisheries Rpt.* 1896, pp. 672, pls. 62).—In addition to the report of the Commissioner, the volume contains Report on the propagation and distribution of food-fishes, by W. de C. Ravenel; Report upon the inquiry respecting food-fishes and the fishing grounds, by R. Rathbun; and Report of the division of statistics and methods of the fisheries by H. M. Smith. The appendix includes, among other articles, the following: Notes on the extension of the recorded range of certain fishes of the United States coasts, by H. M. Smith and W. C. Kendall; Notes on the food of four species of the cod family, by W. C. Kendall; Report of a survey of the oyster regions of St. Vincent Sound, Apalachicola Bay, and St. George Sound, Florida, by F. Swift; List of the available publications of the Commission; Statistics of the fisheries of the interior waters of the United States, by H. M. Smith, and notes on the fisheries of the Pacific coast in 1895, by W. A. Wilcox.

Report of the Commissioner [of Fish and Fisheries], 1897 (*U. S. Com. Fish and Fisheries Rpt. 1897*, pp. CLXXI + 340, pls. 80, figs. 36).—The volume contains the report of the Commissioner; Report on the propagation and distribution of food-fishes, by W. de C. Ravenel; Report of the division of scientific inquiry, by H. M. Smith; Report of the division of statistics and methods of the fisheries, by H. M. Smith; and Report on the work of the *Albatross*, by J. F. Moser. The appendix contains "A manual of fish culture." (See below.)

A manual of fish culture, based on the methods of the United States Commission of Fish and Fisheries (*U. S. Com. Fish and Fisheries, 1897*, pp. 340, pls. 80, figs. 36).—The volume contains detailed directions for the culture of salmon, trout, bass, and other fresh-water and salt-water fish; also chapters on the American lobster, transportation of fish and fish eggs, spawning season, character of fish eggs, period of incubation, the edible frogs of the United States and their artificial cultivation, oyster culture, and clam culture.

METEOROLOGY—CLIMATOLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review, 26 (1898), Nos. 1, pp. 139-193, charts 8: 5, pp. 195-240, fig. 1, charts 13: 6, pp. 241-290, charts 7*).—In addition to the usual meteorological summaries, No. 4 contains special articles on **A** visit to the highest meteorological station in the world, by R. de C. Ward; Seismic and oceanic noises, by S. W. Kain; Meteorological work in Alaska, by A. J. Henry; The international aeronautical conference, by A. L. Rotch; The eighth general meeting of the German Meteorological Society, by A. L. Rotch; Climatic data bearing upon the culture of the date palm, by A. J. Henry; Temperatures obtained by kites at Bergen Point, New Jersey, by H. L. Allen; Rainfall of Masaya and Granada, Nicaragua, by A. J. Henry; and notes by the editor on the rainfall and outflow of the Great Lakes, mountain stations in Australia, tin roofs as lightning conductors, temperature of lake water, meteorology of the second Wellmann expedition, notes from reports of the climate and crop sections, recent earthquakes, and lightning on the kite wire.

No. 5 contains special contributions on Moisture tables, by C. F. Marvin; The umbrella cloud, by W. D. Johnson; Voluntary meteorological and crop reporting stations, by F. J. Walz; and Observations in the Klondike, by U. G. Myers; and notes by the editor on convention at Omaha, evaporation and temperature, climatology, Blue Hill observatory, insurance against drought, the character of the evening, climate of Liberia, the rainfall and outflow of the Great Lakes, oceanic and seismic noises, electrical storms in Kansas, meteorological superstitions, frost formation and ice columns, prairie skies, a new gas in the atmosphere, notes from the reports of the climate and crop sections, and recent earthquakes.

No. 6 contains special contributions on **A** new method of observing the direction of movement of the atmosphere, by H. W. Clough; Kites within a thunder cloud, by T. Hovenden; Meteorological extremes at Northfield, Mass., by A. D. Elmer, Jr.; and Rainfall at Firmeza, near Santiago, Cuba, by J. Monroe; and notes by the editor on seasonal

forecasts in Oregon, meteorological observations in the Klondike, Weather Bureau service in Alaska, notes from the June reports of the climate and crop sections, a high rainbow, lightning on the kite wire, currents induced by distant lightning, new use for kites—the telephone kite, safety fuse for lightning on the anemometer, which trees attract lightning, tin roofs as lightning conductors, rain gushes and thunderstorms, the origin of atmospheric electricity, anomalous and sporadic auroras, moonshine and frost, waterspouts, periodic fluctuation of the Great Lakes, historic droughts in the United States, international balloon ascensions, June 8, 1898, the Smithsonian weather predictions, Broun's law of winds and currents, seasonal forecasts in India and America, earthquakes in New Brunswick, recent earthquakes, mathematics and meteorology, and meteorology by correspondence.

Climate of Cuba; also a note on the weather of Manila, W. F. R. PHILLIPS (*U. S. Dept. Agr., Weather Bureau Bul. 22, pp. 23*).—This is a brief compilation of all available data on temperature, rainfall, and other climatic features of the island of Cuba, with a brief note on weather conditions at Manila, in the Philippine Islands. For purposes of comparison the temperature, rainfall, and number of rainy days at Washington, D. C., and New Orleans, Louisiana, have been introduced in several of the tables.

“The average summer temperature (June, July, and August) of Habana is 82° F., that of New Orleans 81.6° F., and that of Washington 75° F. The highest temperature recorded in 10 years at Habana was 100.6° F., while at Washington the highest temperature has been 104° F. The average annual rainfall at Habana is 51.73 in., and is less than that at New Orleans, which is 60.52 in.; the rainfall at Washington is 44.70 in. . . . During [30 years] 5 occasions have happened when as much, or more, rain fell in the usual dry season as in the rainy season. The average amount of rain falling in the rainy season, which extends from May to October, is 32.37 in. In the same months the average rainfall for New Orleans is 27 in., and for Washington 24.10 in.

“[At Manila] the average temperature of the year is 80° F. The months of April, May, and June are the hottest part of the year. May, with an average temperature of 84° F., is the hottest of the three. December and January are the coolest months, each with an average temperature of 77° F. The highest thermometer reading recorded is 100° F.; this was observed in May. The lowest reading recorded is 74°, and was observed in January.

“The average relative humidity is 78 per cent. That of the most humid month, which is September, is 85 per cent, and that of the least humid month, which is April, is 70 per cent. The average absolute humidity is 8.75 grains in a cubic foot. It is greatest in August and least in February.

“The average annual rainfall is 75.43 in., of which 43.69 in., more than 57 per cent, fall during the months of July, August, and September, and 50.74 in., more than 80 per cent, fall from June to October, inclusive. September has the largest average fall, 15.01 in., and February the smallest average fall, 0.47 in. The heaviest rainfall in any one month was 61.43 in., in September, and sometimes no rain at all has fallen in February, March, April, and May.

“Departures from the average rainfall are in some instances remarkable. For example, as much as 120.98 in. have fallen in one year and as little as 35.65 in. in another. Still more remarkable was the fall of 61.43 in. in one September, and that of only 2 in. in another September.”

The necessity of studying the haze, A. A. SCHULZ (*Rpt. Sci. Comm. Min. Agr. and Gort. Estates, St. Petersburg, 1897, pp. 12; abs. in Selsk. Khoz. i Lyesor., 187 (1897), Nov., p. 112*).—Among the meteorological factors unfavorable to vegetation the haze, which is often observed in eastern and southeastern Russia, is of considerable importance. Several opinions exist concerning the origin of this phenomenon, which acts very injuriously, especially on the ripening of cultivated plants. Some regard it as a result of the earth's storms; others believe it to be the smoke of forest and moor fires; still others consider it as a purely local phenomenon which may be induced by different causes (dust storms, evaporation from the soil, etc.). The question as to the real cause of this phenomenon, however, remains open because of insufficient study. In view of the importance of reaching a solution of this question the author recommends that observations on haze be made a part of regular meteorological observations and gives an outline plan of observations on this subject. It is stated that the Russian scientific bureau, acting upon the suggestion of the author of the report, has adopted measures for gathering more data on this subject.—F. FIREMAN.

Weather freaks of the West Indies, F. L. OSTWALD (*Pop. Sci. Mo., 53 (1898), No. 6, pp. 789-793*).—Popular notes on the nature and causes of the sudden hot and cold waves, droughts and cloud-bursts, and hurricanes, cyclones, and stifling calms which characterize the climate of the West Indies.

Investigation of the cyclonic circulation and the translatory movement of West Indian hurricanes, BENITO VÍÑES (*U. S. Dept. Agr., Weather Bureau Doc. 168, pp. 34*).—This is a translation by C. Finley of an article prepared for presentation to the Meteorological Congress at Chicago in 1893, which the chief of the Weather Bureau regards "as the most satisfactory statement of the laws and phenomena of these storms which has yet been made."

The influence of vegetation on climate and rainfall, J. G. O. TEPPEL (*Adelaide Observer, 1898, May*).

On the influence of forests on the occurrence of hail in European Russia, V. A. TARGONSKI (*Moscow: Society for Insurance of Crops Against Hail, 1898, pp. 171 + 103, map 1; rev. in Selsk. Khoz. i Lyesor., 189 (1898), Apr., p. 224*).—The author concludes that the contour of the surface of the soil, its composition, and the distribution of forests are the chief invariable factors of hail phenomena.—P. FIREMAN.

Instructions for obtaining and tabulating records from recording instruments, C. F. MARVIN (*U. S. Dept. Agr., Weather Bureau Doc. 167, pp. 31, figs. 2*).—A manual designed especially for Weather Bureau observers.

Instructions for aerial observers, C. F. MARVIN (*U. S. Dept. Agr., Weather Bureau Doc. 166, pp. 33, pls. 3, figs. 14*).—A manual of instruction "for the guidance of aerial observers in the care and management of instruments and apparatus employed in making aerial observations with kites."

On an absolute actinometer, A. CROVA (*Compt. Rend. Acad. Sci. Paris, 126 (1898), No. 20, pp. 1394-1398*).

On the rainfall, quantity of snow, and evaporation in the river basins of European Russia, E. A. HEINZ (*St. Petersburg, 1898, pp. 54 + XXXIV; rev. in Selsk. Khoz. i Lyesor., 189 (1898), June, pp. 716, 717*).

Normal annual sunshine and snowfall, A. J. HENRY (*U. S. Dept. Agr., Weather Bureau Doc. 162, pp. 5, chart 1*).—The annual percentage of sunshine and the total annual snowfall by calendar years for each of the regular Weather Bureau and Canadian stations are shown in tables and in a colored chart. The amount of snowfall is given in inches as it lay on the ground.

Annals of the magnetic and meteorological observatory of the Imperial Novorussian University at Odessa, 1896, A. KLOSSOVSKI (*Odessa, 1897, pp. 85+CCCLXXXVI; abs. in Selsk. Khoz. i Lyesor., 188 (1898), Feb., p. 470*).

Meteorological observations, J. E. OSTRANDER and A. C. MONAHAN (*Massachusetts Hatch Sta. Met. Buls. 112, 113, and 114, pp. 4 each*).—These bulletins contain the usual weather notes and summaries of meteorological observations during the months of April, May, and June, 1898.

Monthly bulletins of the River and Flood Service for April, May, and June, 1898, P. MORRILL (*U. S. Dept. Agr., Weather Bureau Doc. 160, pp. 30, chart 1: 164, pp. 14, chart 1: 169, pp. 14, chart 1*).—In addition to the usual data, the April bulletin contains special reports on the saving of life and property in the lower Mississippi Valley as a result of Weather Bureau flood warnings during the spring of 1897.

Meteorological review. Report of the meteorological service of the southwest of Russia in 1896. Second ten-year period, I. A. KLOSSOVSKI (*Odessa, 1897, pp. 87; abs. in Selsk. Khoz. i Lyesor., 188 (1898), Feb., p. 469*).

Report of the Chief of the Weather Bureau, 1896-97 (*U. S. Dept. Agr., Weather Bureau Rpt. 1896-97, pp. X+431, pls. 61, charts 33*).—This report is divided into eight parts. Part I is an administrative report, which has already been noted (*E. S. R., 9, p. 630*). Part II gives a list of observing stations; hourly averages of atmospheric pressure, temperature, and wind from records of automatic instruments at 28 stations; average temperature and pressure in inches and thousandths for each hour of 75th meridian time; velocity and frequency of wind; and monthly mean values of pressure, temperature, and wind for the Instrum 1891-1895. Part III gives monthly and annual meteorological summaries for 142 Weather Bureau stations. Part IV gives monthly and annual means and extremes of temperature and dates of first and last killing frosts. Part V reports monthly and annual precipitation. Part VI gives miscellaneous meteorological tables, charts, and reports, including pressure distribution and prevailing winds, January and July; normal temperature; charts of sea-level temperature; monthly departures of temperature and precipitation in 1896 by geographic districts; cloudiness; relative humidity; sunshine, snowfall; descriptions of local storms and tornadoes; and the West India hurricane of September 29 and 30, 1896. Part VII is devoted to the amount, variation, and distribution of rainfall in the United States by seasons and by districts. Part VIII is a report on floods of the Mississippi River, which has already been noted (*E. S. R., 9, p. 816*).

WATER—SOILS.

A preliminary report on the soils of Florida, M. WHITNEY (*U. S. Dept. Agr., Division of Soils Bul. 13, pp. 31, pls. 6, figs. 3*).—The types of soils reported on are, first, second, and third quality high pine land; pine flats of the so-called "flat woods;" the light hammock, the gray or heavy hammock, mixed land, heavy marl hammock; pineapple land; Etonia scrub, the spruce-pine scrub; and the Lafayette formation.

"The principal localities and interests examined were the truck areas around Gainesville, Ocala, Orlando, Grand Island, Bartow, and Fort Meade; the tobacco areas of the Lafayette or 'red-land' formation at Quincy, as well as the new tobacco areas at Ocala, Bartow, and Fort Meade; the pineapple districts at Orlando, Winterhaven, and along the east coast from Fort Pierce to Palmbeach; also the extensive scrub lands at Altoona known as the Etonia scrub."

Four grades of pine lands are noted—pine flats or "flat woods," and first, second, and third quality of high pine lands. Of these the second quality of high-pine lands are the most extensive and important. These

soils are especially adapted to truck growing on account of the evenness of the water supply which they maintain. Four per cent of water seems to be an abundant supply, and 6 per cent makes the soil quite wet.

“Nearly every important variety of truck crops is grown upon these soils.

“Truck crops seldom suffer on these soils from drought. It is claimed that in one year a crop of tomatoes was secured with but 1 in. of rain from the planting to the harvesting of the crop. Certainly a dry period which would cause a most disastrous drought upon the soils at the North appears to have hardly any effect on the crops of these truck soils. Several weeks after a rain the soil immediately under the dry surface is so moist that it will hold together when molded in the hand.”

The hammock lands are characterized by a native growth of hardwood trees, principally of oak, hickory, magnolia, dogwood, and the cabbage palmetto, and are considered the most valuable in the State for general agricultural purposes. They have proved especially valuable for the culture of tobacco. They maintain on the average about 8 per cent of water.

“[In order to secure the tobacco crop from injury by drought] a very thorough system of irrigation is being practiced on the hammock lands. It is claimed that the crop matures in from 45 to 50 days under judicious irrigation, against 60 to 70 days without irrigation. It is also claimed that it makes finer wrapper leaf.

“The irrigation outfit consists of an engine placed near a water course, with a capacity of about 1 horsepower per acre, and 1-in. or 1½-in. iron pipe laid near the surface of the ground for mains and laterals, the laterals being about 100 ft. apart, with hydrants every 50 ft. Tanks are frequently used, but it is considered preferable now to pump directly into the mains so as to insure sufficient pressure. Nozzles are used which give an even spray, and which are moved from hydrant to hydrant by an attendant as the work progresses. Such an irrigation plant for a field of 20 acres or over costs from \$100 to \$150 per acre. Where the hydrants are not sufficiently close to cover the ground with spray a hose is used with a movable spray to water the space between the laterals.

“Very recently the method of shading, which has been used with great success in the pineapple fields, has been adopted in connection with the tobacco.”

On the Etonia scrub lands there is a dense growth of scrub oaks and low bushes and plants. No grass is found, and only the most hardy desert plants grow. The border line between these soils and the high pine land, on which the trees are large and vigorous and the ground covered with grass, is sharply defined. “There is no apparent reason, from the chemical or physical examination, to account for this difference in the native growth,” on the two kinds of land.

Pineapples are grown extensively on the high pine lands. On these the soil is a coarse, almost pure white sand, apparently devoid of plant food. The subsoil is either a coarse white or yellow sand. As regards physical condition, as well as chemical composition, these soils appear to be absolutely unsuited to agricultural purposes. Nevertheless, with proper fertilizing, shading, and irrigating they have proved very valuable for the production of pineapples.

The soils of the Lafayette formation in western Florida are fine, light, sandy loams, resting upon what appears to be a strong clay subsoil of considerable depth. The loam soil contains about 5 per cent of clay,

the subsoil upward of 30 per cent. However, these soils contain only about 8 or 10 per cent of water as compared with 18 to 22 per cent maintained by similar soils in Pennsylvania and Ohio.

A comparison of the mechanical analyses of different Florida soils shows a great similarity in composition and texture. The percentage of clay is, as a rule, very low. No difference was found in the texture of these soils which would in any way explain the differences in their natural vegetation and agricultural value. Chemical examination and determination of the soluble salt content in the different types of soil showed that not only is there a small amount of plant food present in the soil, but that only about 1 per cent of it is present in soluble form.

“These results all seem to show that these types of Florida soil constitute a distinct class of soils, unlike the average soils of the humid portions of the United States.”

Determinations of moisture in these different soils show that their moisture supply is very uniform, and that a much lower percentage of water suffices for natural vegetation and for different cultivated crops on these soils than on similar soils in other regions. Thus, it was found that the hammock soil maintains on an average only 8 to 9 per cent of moisture, and that this is amply sufficient for the growth of oaks and other hard-wood trees, while at least 15 or 20 per cent of water is necessary for oaks and similar hard-wood trees on soils in the North. Moisture determinations in the scrub and adjacent high pine land showed no apparent difference in the moisture content of these 2 soils during the dry season.

Detailed analyses of the different samples of soils and subsoils are given in tables.

The bluff and Mississippi alluvial lands of Louisiana, W. W. CLENDENIN (*Louisiana Stas. Special Rpt. Geology and Agriculture, pt. 4, pp. 259-290*).—This is a continuation of the geological and agricultural survey of Louisiana which has been prosecuted for a number of years (*E. S. R.*, 8, p. 382). In the preceding report (pt. 3), brief consideration was given to the bluff lands of east and southwest Louisiana. The present report is confined to “a preliminary study of the border lands of the Mississippi River which are directly the product of the river itself.” These are comprised within “a somewhat irregular zone stretching over about 4° of latitude and varying in width from about 15 miles at the Arkansas line to about 100 miles from the line of Five Islands on the southwest to Tickfaw River on the northeast.” The bluff lands east of the Mississippi cover an area of about 1,000 square miles. Those bordering the alluvium of the west are of “such an irregular and indeterminable extent that it is difficult to estimate the amount in square miles.” The topography, drainage, mineral products, and vegetation of these soils are briefly noted.

The alluvial soils are classified as (1) front lands, (2) back lands, (3) swamp, and (4) deep swamp. The front lands are the border lands of

the Mississippi and all of its bayous. They are made up of sandy soils on which the characteristic vegetation is the live oak. The soils of the back lands are finer in grain, and contain more clay than those of the front lands. The clay breaks up under cultivation into small rounded masses, which have given the name "buckshot" to these soils. These 2 classes of soils constitute at present the cultivated portion of the Mississippi alluvium. It is difficult to obtain a sufficient supply of good water in this region. It is suggested that the difficulty may be overcome, at least in part, by the sinking of artesian wells.

"As the front lands grade into the back lands, so these grade into the swamp. The areas thus designated, while not so easily drained as the back lands, are nevertheless capable of thorough drainage. They are considered as swamp and useless for cultivation only because under conditions that have existed in the past they have been too frequently overflowed to make their clearing and cultivation profitable. Under a system of protection that will shut out the flood waters from the master streams they will become available for cultivation. At present they are not so.

"Their tree growth consists chiefly of sweet and black with some tupelo gum, large and abundant; abundant ash of sufficient size and quality to make it valuable for manufactures; scaly-bark hickory; elm; red maple; white, water, and willow oaks; sycamore; and cypress. The undergrowth, while still dense, is marked by a failing of the cane. At present these swamp lands are chiefly valuable for their supplies of hard-wood lumber. Their adaptation to cultivable uses, while possible, must wait upon their greater security from inundation.

"The deep swamp area, chiefly valuable for its forests of cypress and gum, is subject to too deep and too frequent inundation ever to be used for cultivation; at any rate, not until more available lands prove insufficient for the increased population."

Attention is called to the large number of navigable streams in this region, and suggestions are made regarding protection against overflow. Although the soils of the region have been heretofore considered valuable chiefly for the production of cotton, recent experiments have shown that they are capable of producing a superior grade of cigar-wrapper tobacco. The bluff lands also produce sugar cane with an unusually high sugar content. The famous Perique tobacco is grown on the alluvial lands of this region, and they have also been shown to be preeminently suited to alfalfa. Near New Orleans, market gardening on the alluvial soils has proven very profitable, and in the extreme southern part of the region orange culture has brought good returns. The adaptability of the waters of the region to fish and oysters and the rapid development of oyster culture in the coastal bayous and bays are pointed out. The results of the examinations of the soils of the region are reserved for a future report.

The fertility of Oregon soils, G. W. SHAW (*Oregon Sta. Bul. 50, pp. 56, pl. 1*).—This is a continuation of work previously reported in Bulletin 21 of the station (E. S. R., 4, p. 464). A general discussion is given of the importance of chemical analysis of soils, origin of soils, functions of soils, constituents of soils and their functions, and texture of soils. The natural divisions of the State are described, and analyses, including determinations of coarse material, fine earth, water capacity,

hygroscopic moisture, organic matter, humus, and mineral constituents of 71 samples of soils from the different sections of the State are reported. The averages for the main divisions of the State, as well as for the State as a whole, are given in the following table:

Average composition of Oregon soils.

Analysis of fine earth.	Willamette Valley.	Southern Oregon.	Eastern Oregon.	Average for whole State.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Insoluble matter.....	65.18	62.45	66.59	65.08
Soluble silica.....	5.02	8.74	13.12	7.69
Potassium oxid.....	.23	.34	.43	.32
Sodium oxid.....	.18	.21	.22	.29
Calcium oxid.....	.83	2.22	1.22	.97
Magnesium oxid.....	.79	.80	.75	.82
Mangano-manganic oxid.....	.08	.25	.19	.16
Ferrie oxid.....	16.45	15.35	10.69	12.68
Aluminium oxid.....				
Sulphuric acid.....	.03	.01	.04	.070
Phosphoric acid.....	.21	.13	.14	.26
Water and organic matter.....	10.77	9.52	6.21	10.05
Total.....	99.77	100.02	99.51	99.02
Humus.....	1.63	2.25	1.44	2.42

The bottom lands of the Willamette Valley as a rule "have a tendency toward clay loams with clay subsoils forming a hardpan." The soils are divided into dark loam and gray loam, the latter running into the so-called "white lands." They are all, however, of about the same chemical composition. They are rich in phosphoric acid and humus, well supplied with lime, but deficient in potash.

"That these soils should be fairly well supplied with lime would be expected from *a priori* reasons on account of the basaltic origin of a large part of them. The lime in the valley soils is not altogether in the form of a carbonate—indeed, it is rare that sufficient carbonate is present to cause evident effervescence with acid—but even a casual examination shows a very common occurrence of easily decomposable zeolites, principally mesolite, from which, by weathering, the lime may be constantly supplied."

In the hill country surrounding the Willamette Valley, in its northern part, are found the so-called "shot lands," which contain considerable amounts of iron oxid, together with quartz, feldspar, and some hornblende, the iron oxid cementing the particles of clay together into small nodules which to some extent resemble shot, but which wear away in cultivation. These soils are usually well drained and easily worked, but wash badly in heavy rains. They contain as a rule a fair amount of potash, a limited amount of lime, and are well supplied with phosphoric acid.

The soils of southern Oregon "are stronger than the Willamette Valley soils not only in lime but also in potash, but weaker in phosphoric acid." The soils of eastern Oregon contain more lime than those of the humid or western area. They also contain a larger supply of potash, which is more available than that in the soils of the Willamette Valley. The amount of phosphoric acid, however, is smaller than that of the western soils.

The influence of climate upon the lime content and humus of the soils of these different regions is discussed, as well as the origin and treatment of alkali in the western or arid portion of the State and the adaptability of the various soils to different systems of farming.

The importance of the mineral humates as a nutritive medium for plants, G. NEFEDOV (*Selsk. Khoz. i Lyesor., 181-1897*), *Jan., pp. 111-163*).—The question which the author seeks to answer is whether the phosphorus and nitrogen which enter into the composition of the humus compounds of the chernozem (black Russian soil) are assimilable by the higher plants under the ordinary conditions of cultivation, i. e., in the presence of micro organisms.

The experiments carried out consisted in the first place of a repetition of the experiments of Eggertz with a soil washed with a dilute mineral acid, precautions being taken to carefully neutralize the soil after this treatment, and in the second place in growing plants in humus substances extracted from the chernozem, inoculating the humus extract with the bacteria of the soil. In order to neutralize the soil after treatment with the acid and distilled water the free humic acids were saturated with calcium carbonate.

The experiments were made with the chernozem of the Tula Government. The composition of the air-dried soil was as follows:

Analysis of air-dried chernozem.

	Per cent.
Hygroscopic water.....	5.97
Humus with water of crystallization.....	10.16
Phosphoric acid obtained by igniting the soil and treatment with boiling 30 per cent hydrochloric acid.....	.1702
Nitrogen.....	.377
Air-dried humic acid (calculated to ash-free matter).....	1.87

In the humus there was found 1.88 per cent of phosphoric acid, which represents 51.6 per cent of all the phosphoric acid of the soil.

In the repetition of Eggertz's experiments part of the soil was treated with 1 per cent hydrochloric acid and part with 3 per cent. After washing with distilled water a small portion was at once dried on filter paper, while the greater part was first mixed with chalk, using 100 gm. of chemically pure carbonate to 200 gm. of the air-dried soil. Before placing in the glass cylinders where the plants were grown the various soil samples were pulverized and mixed with different nutritive solutions.

The material for the experiments with the pure calcium humates was prepared as follows: The soil was treated with 1 per cent hydrochloric acid, washed with distilled water, dried on filter paper, pulverized, and placed in layers 1 cm. thick in tin sieves whose bottoms were covered on the inside with a layer of filter paper. The soil was treated with ammonia solution (1 part of strong ammonia and 3 parts of water), the solvent remaining in contact with the soil for from 15 to 30 minutes, and then the soil was washed with distilled water. The black extract

fell drop by drop into a $\frac{1}{2}$ to 1 per cent solution of hydrochloric acid, where it was precipitated in flakes and settled at the bottom of the vessel. The humic acid was transferred to a folded filter and washed first with 0.25 to 0.5 per cent hydrochloric acid and then with distilled water. The washed humic acid was mixed first with chalk and then with white quartz sand, which had been treated with aqua regia and washed with distilled water.

Three series of experiments were carried out. (1) with soil treated with 3 per cent hydrochloric acid in 13 pots planted to barley, oats, lupines, and peas; (2) with soil treated with a 1 per cent solution of hydrochloric acid in 4 pots planted to barley, and (3) with calcium humate in 8 pots planted to barley and peas.

The chief results obtained may be summed up as follows:

(1) The chernozem soil treated with a 3 per cent solution of hydrochloric acid and inoculated with the micro-organisms of the soil contains easily assimilable nitrogen and phosphorus in quantities sufficient for the formation of the vegetative organs of barley.

(2) Calcium humate containing no mineral admixtures may be obtained by mixing gelatinous humic acid with calcium carbonate, which is decomposed under these conditions with the evolution of carbon dioxide.

(3) The humic acids extracted from the chernozem by successive treatment with acid and alkali, even when in the form of calcium salts, disturb the regular development of plants, causing an intensified formation of shoots and rendering impossible the formation of the reproductive organs.

(4) Potassium phosphate renders the poisonous properties of the artificially obtained calcium humates more marked.

(5) The poisonous action of the calcium humates is probably due to the presence of ferrous oxid in the humus substances formed by the reduction of the ferric oxid during the process of the extraction of the humic acids.

(6) The opinion of Hoppe-Seyler that the humus substances are unalterable under the ordinary conditions of the soil and in no measure serve as food for the lower organisms is erroneous. The humus substances extracted from the chernozem by chemical means either in soluble form or insoluble form, when acid in reaction as well as when feebly alkaline or neutral, in the presence as well as in the absence of air, are a very suitable nutritive medium for the growth of the lower organisms.

(7) The phosphorus and, apparently, the nitrogen of calcium humate in the presence of the micro-organisms of the soil contribute to the growth of the higher plants (barley).—P. FIREMAN.

Review of the literature of soils, L. OCHAPOVSKI (*Selsk. Khoz. i Lyesor.*, 190 (1898), July, pp. 147-186).

Soil bacteria in their relation to agriculture, I. F. D. CHESTER (*Delaware Sta. Bul.* 40, pp. 16, figs. 2).—This is a popular summary of information on this subject.

The topics treated are the elements and sources of plant food, the nature and origin of soils, the number and distribution of soil bacteria, and the chemical changes produced by bacteria.

FERTILIZERS.

Contribution to the solution of the question of the extent to which the potash requirements of soil can be determined by analysis of the plant and the soil, O. LEMMERMANN (*Laudw. Vers. Stat.*, 49 (1897), Nos. 4-5, pp. 287-339).—Both field and pot experiments on this subject are reported. Experiments in the field were made on unfertilized soils and those which had received kaimit at rates of 1,000 to 2,000 kg. per hectare (about 890 and 1,780 lbs. per acre). The crops grown were oats, wheat, and rye. The potash content of the soils was determined by digesting 200 gm. with 400 cc. of 10 per cent hydrochloric acid on a boiling water bath for 3 hours. The attempt was made first to determine what amount of potash soluble in this reagent is necessary in a soil in order to produce normal crops. It was found in these experiments that a soil containing 0.24 per cent of potash soluble in 10 per cent hydrochloric acid was not improved for the production of oats by applications of potassic fertilizers, although the yield of wheat and rye on such soils was considerably increased by applications of such fertilizers. No relation was observed between the amount of potash in the soil and that found in the plant. Samples of soil were treated with $\frac{1}{16}$, $\frac{1}{4}$, $\frac{1}{2}$, 1, and 5 per cent hydrochloric acid, the soil so treated being used in pots for the growth of oats. The object in this case was to determine the exact strength of acid and method of treatment which would remove all of the potash assimilable by oats. The experiments, however, gave negative results because the oats grew best in the soils which had been exhausted with the stronger acid. The author believes this to be due to chemical changes which render the potash not dissolved by the acid more accessible to the roots of the plants and at the same time more assimilable. Contrary to the results obtained in the field, the potash content of oats grown in pots increased with the amount of this substance applied to the soil.

The liming of soils, H. J. WHEELER (*U. S. Dept. Agr. Farmer's Bul.* 77, pp. 19).—This bulletin discusses the use of lime for improving soils, its manurial and chemical action, its physical effects, and its effects on the action of microscopic organisms in the soil. The conditions under which lime may be injurious are pointed out. The influence of lime upon some plant diseases is noted and directions for the application of lime to soils are given. Fifteen forms of lime used for agricultural purposes are described.

“There are many soils in which lime is deficient, notably in soils derived from granite, mica schist, and sandstone formations. On such soils lime is of direct value in supplying a necessary element of plant food.

“The indirect value of lime is perhaps more important than its direct action, because probably the majority of cultivated soils contain sufficient lime to meet the direct demands of plants. Lime is of indirect value in unlocking the unavailable potash, phosphoric acid, and nitrogen in the soil.

"Lime exerts a decided influence on the mechanical condition of soils, rendering heavy, compact soils looser in texture and tending to bind particles of loose leachy soils.

"Lime is also beneficial in furnishing conditions in the soil favorable to the activity of the micro-organisms which convert the nitrogen of organic matter into nitrates which are readily assimilated by plants, which decompose organic matter, and which assist leguminous plants to assimilate the free nitrogen of the air. . . .

"The continued use of lime unaccompanied by other fertilizers may prove injurious, especially on poor soils, since it converts the insoluble nitrogen, potash, and phosphoric-acid compounds of the soil into forms which are rapidly taken up by plants or washed out in the drainage, and thus hastens the exhaustion of the supply of these substances in the soil. If the soil is not abundantly supplied with organic matter, its retentive power for water and fertilizers may be seriously reduced on account of the destruction of the organic matter by the action of too much lime. Soils are sometimes injured by applications of impure forms of lime, which harden like cement in the soil, or of those which contain an excessive amount of magnesia.

"It has been shown that even many upland and naturally well-drained soils apparently in good condition otherwise are so sour (acid) that most plants will not thrive on them. The application of caustic lime is the most economical and effective means of correcting this condition.

"According to experiments made by the Rhode Island Experiment Station on acid soils in that State, the plants tested may be classified with regard to their behavior toward lime as follows: Plants benefited by liming—spinach, lettuce, beets (all kinds), gumbo (okra), salsify (vegetable oyster), celery, onion, parsnip, cauliflower, cucumber, eggplant, cantaloupe, asparagus, kohlrabi, cabbage, dandelion, Swedish turnip, pepper, pea, peanut, martynia, tobacco, sorghum, alfalfa, clover, barley, wheat, oats, timothy, and Kentucky bluegrass; plants injured by liming—serradella, watermelon, blue lupine, and common sorrel (*Rumex acetosella*); plants indifferent to liming—Indian corn, common millet, Hungarian, golden millet, rye, potatoes, carrots, Rhode Island bent (grass), and redtop (grass)."

Commercial fertilizers, M. A. SCOVELL, A. M. PETER, and H. E. CURTIS (*Kentucky Sta. Bul.* 75, pp. 77-91).—This bulletin gives the text of the amended State fertilizer law, which went into effect March 14, 1898, with a brief discussion of the amendments; and tabulated analyses and valuations of 102 samples of fertilizing materials inspected during 1898.

"The new law requires manufacturers to make affidavit to the director [of the experiment station] guaranteeing the minimum analysis of each brand of fertilizer which they propose to sell in the State, and the director shall print this guaranteed analysis over his facsimile signature in the form of a tag, and every package of fertilizer sold or offered for sale in the State shall have one of these tags attached, and this tag analysis shall be the standard by which the fertilizer is to be judged. The tag shall also show the net weight of fertilizer contained in each package. The manufacturer also sends to the director a fair sample of each kind of fertilizer which he proposes to put on sale. The director is given authority to take samples for analysis from any fertilizer on sale in the State, and is required to make every year at least one analysis of each kind of fertilizer that has been entered for sale. The law also provides that any purchaser of a fertilizer, who is not an agent or dealer, may take a sample of the same, under proper regulations, and have it analyzed at the station free, and such purchaser shall not be required to give the name of the fertilizer or of the person from whom it was bought until after the analysis has been made and reported. But after the purchaser has received the report of analysis he must give the director all information about the fertilizer that may be required for publication

in the station bulletins or for prosecution of the case if it appear that the law has been violated.

“Under the new law the estimated value per ton is not given on the tag. It was thought best to leave it off for two reasons—first, because the ingredients of which fertilizers are made vary in price from time to time during the year, and as the tags are good for a year, or until used, the estimated value might not represent anywhere near the true valuation during a portion of the year, at least; and, second, because it is much more important that the farmer should buy on the percentage of phosphoric acid, nitrogen, and potash in the fertilizer than on the estimated value.”

The phosphate deposits of Arkansas, J. C. BRANNER (*Trans. Amer. Inst. Min. Eng.*, 26, pp. 580-598; *abs. in Tech. Quart.*, 11 (1898), No. 2, *Rev. Chem.*, p. 51).—A detailed account of unworked deposits. Analyses of the phosphatic nodules show from 22.62 to 33.86 per cent of phosphoric acid.

Fertilizer inspection, C. D. WOODS, J. M. BARTLETT, ET AL. (*Maine Sta. Bul.* 43, pp. 8).—This bulletin contains the analyses of 125 manufacturers' samples of fertilizers licensed before February 25, 1898, with a brief summary of the chief provisions of the State fertilizer law.

The cost of plant food in Connecticut, spring months of 1898 (*Connecticut State Sta. Bul.* 127, pp. 10).—This bulletin contains a schedule of trade values of fertilizing ingredients for 1898; notes on the purchase of fertilizers and on the cost of nitrogen in nitrate of soda, sulphate of ammonia, dried blood, cotton-seed meal, and castor pomace; phosphoric acid in dissolved boneblack and acid phosphate, and potash in high-grade sulphate, double sulphate of potash and magnesia, muriate of potash, carbonate of potash, and cotton-hull ashes; and analyses of 7 samples of fertilizing materials, including mixed fertilizers, bat guano, rape-seed meal, and street sweepings. Determinations of the solubility of the organic nitrogen of 5 of the fertilizers in pepsin solution are also reported.

Analyses of commercial fertilizers, T. J. EDGE and W. FREAR (*Pennsylvania Dept. Agr. Bul.* 37, pp. 40).—This bulletin gives the text of the State fertilizer law, notes on valuation, and tabulated analyses and valuations of 591 samples of fertilizing materials inspected during the period from January 1 to August 1, 1898.

Analyses of commercial fertilizers, M. A. SCOVELL, A. M. PETER, and H. E. CURTIS (*Kentucky Sta. Bul.* 71, pp. 115-123).—This bulletin gives the trade values of the essential fertilizing ingredients for 1898, which are the same as those for 1897, and tabulated analyses and valuations of 34 samples of fertilizers examined since the publication of Bulletin 68 of the station (*E. S. R.*, 9, p. 338).

FIELD CROPS.

Experiments with different kinds of fertilizers in 1896 on the Kazan Experimental Farm (*Selsk. Khoz. i Lyosov.*, 185 (1897), May, pp. 263-282).—Experiments were made with rye, oats, potatoes, and clover with timothy for hay.

Rye.—Three series of experiments were made with rye. The object of the first series was to study the influence on the yield of rye of the following fertilizers: (1) Barnyard manure 35,600 lbs. per acre, (2) barnyard manure with 416 lbs. of superphosphate, (3) green manure, (4) green manure with 416 pounds of phosphate, (5) green manure with 416 lbs. of potash, (6) green manure with 356 lbs. of Berliner's bone meal A (4.5 per cent of nitrogen and 24 per cent of phosphoric acid), and (7) green manure with 178 lbs. of Berliner's bone meal B (0.6 per cent of nitrogen and 31 per cent of phosphoric acid). The plats, 0.45 acres each, were sown in 1890 under clover with timothy. The tabu-

lated results show that green manure with phosphate gave a decrease of 12.9 per cent, with potash 2.6 per cent; and green manure alone gave an increase of 5.3 per cent, green manure with bone meal A 6.25 per cent, green manure with bone meal B 7.4 per cent, barnyard manure with superphosphate 27.7 per cent, and barnyard manure alone 50.9 per cent.

In the second series of experiments with rye the influence of the following fertilizers was studied: (1) Superphosphate 416 lbs. per acre, (2) nitrate of soda 416 lbs., (3) Berliner's bone meal A 356 lbs., and (4) Berliner's bone meal B 178 lbs. The tabulated results show an increase of the yield in all cases: For bone meal B 11 per cent, bone meal A 35 per cent, nitrate of soda 35 per cent, and superphosphate 49.6 per cent.

The third series of experiments was designed to study the influence of phosphate and potash as compared with that of manure. Potash was applied at the rate of 416 lbs., and phosphate at the rate of 370 lbs. per acre. The results were as follows: Phosphate gave a decrease of 9 per cent, while potash gave an increase of 0.82 per cent, and manure an increase of 16.8 per cent.

Oats.—The object of the first series of experiments with oats was to investigate the action of the following fertilizers on the yield of oats: (1) Bone meal A 356 lbs. per acre, (2) bone meal B 178 lbs., and (3) nitrate of soda 416 lbs. The results show that nitrate of soda gave a decrease of 30 per cent and bone meal a decrease of 4.4 per cent, while bone meal B gave an increase of 7 per cent.

The second series was carried out on the plats which had been used the preceding year for experiments with rye similar to those of the first noted above. The following fertilizers had been applied the preceding year: (1) Manure alone 35,600 lbs. per acre, (2) manure with 416 lbs. of superphosphate, (3) superphosphate 416 lbs.; and (4) nitrate of soda 416 lbs. The results were as follows: Nitrate of soda gave an increase of 2.5 per cent (the increase of rye the preceding year was 37.2 per cent), superphosphate 5.3 per cent (rye preceding year 2.3 per cent), manure 24.8 per cent (rye preceding year 18.5 per cent), and manure and superphosphate 27 per cent (rye preceding year 12.8 per cent).

The third series of experiments with oats was made on the same plats devoted the preceding year to experiments with rye similar to those of series 2 noted above, the object being to ascertain the influence of the fertilizers under rye on the succeeding oats. The following fertilizers were used: (1) Green manure with 416 lbs. of phosphate, (2) green manure with 416 lbs. of potash, and (3) green manure alone. Green manure alone gave a decrease of 0.28 per cent and green manure with phosphate and potash a decrease of 0.72 per cent; while the preceding year the increase in the first case was 19.5 per cent and in the second case 57.5 per cent.

Experiments were also made on plats on which rye was grown the preceding year with the following fertilizers: (1) Manure 35,600 lbs. per

acre, (2) phosphate 370 lbs. The phosphate, which in the preceding experiments with rye gave an increase of 7.6 per cent, in these experiments yielded 5.1 per cent increase; the manure gave in these experiments 19.4 per cent increase, in the preceding experiments 13.5 per cent increase.

Potatoes.—In the first series of experiments with potatoes the object was to investigate the influence of bone meal, applied both broadcast and in hills, and of nitrate of soda and potash. The following amounts were used: (1) Bone meal A 356 lbs. per acre broadcast, (2) bone meal B 178 lbs. broadcast, (3) potash 267 lbs., (4) nitrate of soda 267 lbs., (5) bone meal A 356 lbs. in hills, and (6) bone meal B 178 lbs. in hills. The potato leaves were affected by rot (*Phytophthora infestans*). All fertilizers gave an increase—potash 3.5; bone meal B broadcast 18.2, in hills 39.8; bone meal A broadcast 20.3, in hills 44.3; and nitrate of soda 55.4 per cent. The greater the yield the less the starch content of the potatoes. Potash alone caused a very slight increase in the yield, but decreased the starch content 0.15 per cent.

In the second series of experiments the influence of double plowing and of planting at a depth of 10.5 to 12.2 in. was investigated. Experiments were also made in which the seed potatoes were soaked for 24 hours in a 2½ per cent solution of copper sulphate, with a view to ascertaining whether this treatment prevents rot and exerts any influence on the yield. The double plowing produced an increase of 6.2 per cent; the treatment with copper sulphate caused a decrease of 9.9 per cent. The starch content was not changed by the double plowing, but the treatment with copper sulphate resulted in a decrease of 1.3 per cent in starch content.

The object of the third series of experiments was to ascertain the influence of spraying the potato leaves with various liquids on the yield and starch content. The following solutions were applied: (1) Limewater, (2) pure water, (3) copper sulphate and limewater, (4) copper sulphate. While spraying with pure water gave an increase of 2.6 per cent and with limewater of 10.8 per cent, spraying with copper sulphate alone caused a decrease of 4.1 per cent and with copper sulphate and limewater a decrease of 0.45 per cent. The starch content decreased with limewater (0.6 per cent), but increased with pure water (0.5 per cent), with copper sulphate alone (0.6 per cent), and with copper sulphate and limewater (1 per cent).

Clover with timothy for hay.—The object of the first series of experiments with these crops was to observe the influence of kainit, nitrate of soda, gypsum, and phosphate-gypsum on the yield of clover with timothy at the first mowing of the first year. Fertilizers were applied as follows: 370 lbs. per acre of kainit and 250 lbs. per acre of the other fertilizing materials. Kainit gave 1.7 per cent, phosphate-gypsum 10.4 per cent, and gypsum 5.9 per cent decrease, and only nitrate of soda gave an increase in yield (6.5 per cent).

The object of the second series of experiments was the same as the first, but was confined to the second and third mowings. In all cases there was an increase, which for the second mowing was 21.5 per cent with nitrate of soda, 17.5 with kainit, 45.6 with phosphate-gypsum, and 21.9 with gypsum alone; and for the third mowing 31 per cent with nitrate of soda, 23.4 with kainit, 34.3 with phosphate-gypsum, and 6 with gypsum.

In the third series of experiments an attempt was made to ascertain to what extent oats as a cover plant decreases the yield of clover with timothy. The yield of hay was 84.9 per cent less with the cover than without it.—P. FIREMAN.

Experiments with field crops, 1897, G. E. MORROW and J. H. BONE (*Oklahoma Sta. Bul. 33, pp. 18, figs. 3*).—Experiments were made with corn, oats, cotton, Kafir corn, millo maize, Jerusalem corn, sweet sorghum, castor beans, sugar beets, stock or "pie" melons, alfalfa, cowpeas, soy beans, grasses, and clovers. Popular notes are given on these crops and the results of experiments are tabulated. Kafir corn planted April 17 and May 1 gave an average yield per acre of 22.3 bu. of grain, while plats planted May 15 and 22 yielded 38.2 bu. The amount of stover produced per pound of grain was 6.1 and 3.4 lbs., respectively. The largest yield of grain (53.3 bu. per acre) was obtained from the plat on which stalks were 3 in. apart in rows 3 ft. apart. In general the plats with the greatest number of stalks gave the largest yield of stover.

A comparison of Indian corn and Kafir corn showed that Kafir corn was much more drought-resisting, but that it grew much less rapidly.

Oats were sown at different rates, but the yields varied little. Of the 9 varieties grown the best yielding were Texas Red, Negro Wonder, Lincoln, and Black Russian in the order given.

Castor beans planted April 13 yielded 12.9 bu. per acre, which was a better yield than was obtained from later plantings.

Report of the agriculturist, J. H. SHEPPERD (*North Dakota Sta. Rpt. 1897, pp. 51-79*).—The work here described is in continuation of that reported a year ago (*E. S. R., 9, p. 741*). The continuation of the variety testing of wheat, oats, barley, and corn did not change the relative rank of the best-yielding varieties reported last year.

Red Kafir corn, white Kafir corn, millo maize, durra, and Jerusalem corn, tested for 4 years, have failed to ripen fully during any season. The results of cultivation experiments are given in abstract form from a former bulletin (*E. S. R., 9, p. 931*). Awnless brome grass (*Bromus inermis*) has given promising results for a number of years. Timothy and clover sown with this grass were crowded out by its vigorous growth. "It should be seeded at the rate of 20 lbs. per acre without a nurse crop." A field of timothy and red clover injured by heavy rains yielded about 1½ tons of hay per acre. The results of a rotation experiment are given in the following table:

Yield per acre in rotation experiment.

	Average for 1893 and 1897.	1893.	1894.	1895.	1896.	1897.
Wheat continuously, average for six plats.....	Bu. 12.1	Bu. 9.4	Bu. 19.6	Bu. 23.3	Bu. 16	Bu. 14.8
First, second, and third wheat crops after barren fallow, average for four plats.....	17.3	15.3	24	24.9		21.3
First, second, and third wheat crops after cultivated crops: corn, peas, rape, potatoes, and manure, average for six plats.....	18.4	16.5	24.8	23.3		20.2
First, second, and third crops of wheat after millet, one plat.....	16.8	13.3	23.8	23		20.3
First, second, and third crops of wheat after timothy and clover for two years, one plat.....				31	20.5	21.6
First crop of wheat after flax for one year, average for one plat.....				23.3		19.5
Second crop of wheat after flax for one year, one plat.....					19.2	
First crop of wheat after flax for three years, one plat.....						22
Flax continuously for three years, one plat.....			9.5	12.6	12.6	
First and second wheat crops after flax followed by fallow, one plat.....			14.5	25		
First, second, and third wheat crops after field peas, one plat.....	17.4	14.4	23.5	23		20.4
First, second, and third wheat crops after green manuring with field peas, one plat.....	11.7	10.4	23.5	23		12.9
First, second, and third wheat crops after manuring with millet, one plat.....	15.6	14.1	22.8	23.5		17
First crop of wheat after potatoes, one plat.....						16.8

Wheat was grown after corn and millet on manured and unmanured plats. The results showed a marked increase in yield from the application of manure.

A study of the castor-oil plant, G. L. HOLTER and J. FIELDS (*Oklahoma Sta. Bul. 32, pp. 11-15*).—The amounts of nitrogen, phosphoric acid, and potash removed from the soils by the different parts of the castor-oil plant were determined and the results are tabulated. Analyses were made of 3 varieties—2 common varieties, the seed of which had been obtained from Oklahoma and Kansas, and 1 ornamental variety. The proportion of beans and hulls for the 3 varieties was approximately 75 per cent of hulled beans and 25 per cent of hulls. The beans were found to contain about 60 per cent of oil. Directions are given for the determination of castor oil in beans. The fertilizing constituents in the different parts of the plant were found to be as follows:

Amount of principal fertilizing elements in the castor-oil plant.

Part of plant.	In one plant.			In 100 parts fresh substance.		
	Nitrogen.	Potash.	Phosphoric acid.	Nitrogen.	Potash.	Phosphoric acid.

“One thousand pounds of castor beans contain 35 lbs. nitrogen, 4 lbs. potash, and 14 lbs. phosphoric acid. The pods gathered with this amount of beans weigh approximately 800 lbs. and contain 13 lbs. nitrogen, 46 lbs. potash, and 1½ lbs. phosphoric acid.”

Cotton and corn experiments, 1897, B. C. PITTSUCK (*Texas Sta. Bul. 45, pp. 977-1008, pls. 5*).—The experiments comprised variety and distance tests with cotton and fertilizer tests with cotton and corn. A description of the soil and climate, chemical and mechanical analyses of the soil, and meteorological data for the entire year are given. The results of the experiments are tabulated, and the results of variety tests with cotton and corn in 1894 and 1895 are summarized. The results of the cotton and corn experiments made in 1894 (E. S. R., 7, pp. 114, 115) are appended in abstract form.

The variety and distance experiments with cotton were made with 5 varieties planted at different distances. The following table shows the comparison of distances of planting and the yields of varieties:

Yield of varieties of cotton at different distances.

Variety.	Group No. 1.		Group No. 2.		Group No. 3.	
	3 by 2 ft. rows.		4 by 2 ft. rows.		4 by 3 ft. rows.	
	Seed lint.	Lint.	Seed lint.	Lint.	Seed lint.	Lint.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Bohemian (check)	970.3	321.3	667.5	218.4	681.3	208.1
Jones Improved	693.7	217.6	681.9	204.5	802.6	273.2
Welborn Pet.	728.2	237.2	690.9	218.7	708.9	217.2
Peterkin. L. C.	806.8	294.2	712.3	219.1	643.0	201.4
Texas Oak	546.5	204.9	613.9	213.5	537.8	184.8

Bohemian, Texas Oak, and Jones Improved gave the largest yield in groups 1, 2, and 3, respectively.

Nitrogenous, phosphatic, and potassic fertilizers were applied to cotton singly and combined. Plats which received boneblack, cotton-seed meal, or cotton-hull ashes at the rate of 500 lbs. per acre produced the best yields of those receiving single applications. Of the complete fertilizers, the application of 200 lbs. acid phosphate and 4,000 lbs. barnyard manure per acre gave the best yield. The best results in the entire test were obtained from the application of 500 lbs. boneblack per acre.

In the fertilizer test with corn, the largest yield followed the application of 500 lbs. per acre of acid phosphate. Of the nitrogenous fertilizers, barnyard manure at the rate of 4,000 lbs. per acre, and of the potash fertilizers, cotton-hull ashes at the rate of 500 lbs. per acre, gave the best yields. Of the complete fertilizers, the application of 100 lbs. kainit, 400 lbs. acid phosphate, and 150 lbs. muriate of potash per acre gave the best results.

Report upon the grasses and forage plants of central Texas, H. L. BENTLEY (*U. S. Dept. Agr., Division of Agrostology Bul. 10, pp. 38, figs. 14*).—This bulletin discusses the early conditions of the ranches of

central Texas and the reasons for their deterioration, and suggests methods for their renewal. Notes are given on the grasses and forage plants mentioned.

The following native grasses and forage plants are recommended for propagation:

Western wheat grass (*Agropyron spicatum*), feather sedge or feather blue stem (*Andropogon saccharoides torreyanus*), bushy blue stem (*A. nutans*), side-oats grama (*Bouteloua curtipendula*), black grama (*B. hirsuta*), blue grama (*B. oligostachya*), rescue or artie grass (*Bromus unioloides*), Arizona millet (*Chatochloa macrostachya*), Bermuda (*Cynodon dactylon*), wild rye (*Elymus canadensis*), everlasting grass (*Eriochloa punctata*), curly mesquite (*Hilaria cenchroides*), wild timothy (*Muhlenbergia racemosa*), white top (*Triodia albescens*), galleta or black grama (*Hilaria mutica*), alkali sacaton (*Panicum bulbosum*), barnyard grass (*P. crus-galli*), beardless barnyard grass (*P. crus-galli muticum*), cotton-top (*P. lachnanthum*), chaparral millet (*P. reverchonii*), hurrah grass (*P. reticulatum*), Colorado or Concho grass (*P. texanum*), switch grass (*P. virgatum*), water grass (*Paspalum pubiflorum glabrum*), Texas crow-foot (*Leptochloa dubia*), drop seed (*Sporobolus cryptandrus*), needle or dog-town grass (*Aristida fusciculata*), and buffalo grass (*Bulbilis dactyloides*).

In addition to the above the following are considered of probable value:

Bur grass (*Cenchrus tribuloides*), wild millet (*Chatochloa italica*), sedges (*Cyperus* and *Carex* spp.), bog rushes (*Juncus* sp.), satin grass (*Muhlenbergia tenuiflora*), grapevine mesquite (*Panicum obtusum*), crab grass (*P. sanguinale*), knot grass (*Paspalum distichum*), wild oats (*Triodia latifolia*), prairie sage brush (*Artemisia ludoviciana*), butterfly pea (*Crotalaria mariana*), bushy knotweed (*Polygonum ramosissimum*), woolly plantain (*Plantago gnaphalioides*), purslane (*Portulaca oleracea*), and cotton purslane (*P. pilosa*).

The following grasses and forage plants are thought to be of little forage value, but worthy of consideration:

Crow's foot (*Chloris cucullata*), feather crow-foot (*C. alba*), love grass (*Eragrostis pilosa* and *E. secundiflora*), stink or candy grass (*E. major*), *Muhlenbergia arenicola*, old witch or tickle grass (*Panicum capillare*), hairy-flowered panic (*P. ciliatissimum*), brown top (*P. fuscum*), Hall grass (*P. hallii*), *Sporobolus drummondii*, fall redtop (*Triodia seslerioides*), gunnainipil (*Allionia incarnata*), tumble weed (*Amaranthus blitoides*), water purslane (*Ammannia coccinea*), white sage, sage brush (*Artemisia mexicana*), ground plum (*Astragalus crassicaarpus*), fox sedge (*Carex rulpinoidea*), star thistle (*Centaurea americana*), lamb's quarters (*Chenopodium album*), grandpa's beard (*Clematis drummondii*), wild sages (*Croton* spp.), red-root sedge (*Cyperus erythrorhizos*), hog nut, chufa (*C. esculentus*), *Ephedra nevadensis*, alfalaria (*Erodium cicutarium*), winter fat (*Eurotia lanata*), rosin weed or gum weed (*Grindelia squarrosa*), dwarf broom weed (*Gutierrezia sarothra microcephala*), sunflower (*Helianthus annuus*), artichoke (*H. tuberosus*), blue weed (*Hoffmannseggia stricta*), wild verbena (*Lippia nodiflora*), bur clover or California clover (*Medicago maculata*), prickly pear (*Opuntia engelmannii*), sorrel (*Oxalis corniculata*), prairie clover (*Kuhnistera* sp.), and the mesquite bean (*Prosopis juliflora*).

Experiments with oats, C. C. GEORGESON, F. C. BURTIS, and D. H. OTIS (*Kansas Sta. Bul.* 74, pp. 195-211).—These experiments were along similar lines to others heretofore reported (E. S. R., 9, p. 42). The results are given in tabular form.

In a comparison of spring-plowed, fall-plowed, and unplowed land

for oats, the best yields for 5 years in succession were obtained from the spring-plowed land. The average yield was 27.4 bu. per acre, or about 2 bu. more than was obtained from the fall-plowed or unplowed land.

In experiments carried on for 5 years the best yields were obtained from oats sown the first or second week in March. These plants also grew taller and had larger panicles than those from later seedings.

Light, common, and heavy oats were used for seed. The common grain was the grain as it came from the thresher. The average yields for 8 years were 27.5, 28.89, and 30.9 bu. per acre, respectively.

Trials with different methods of seeding were carried on for 7 years. The seed was sown broadcast and with a hoe drill, a shoe drill with press wheels, and a shoe drill without press wheels. The average yields were 26.24, 28.34, 30, and 31.54 bu. per acre, respectively.

The average results for 7 years from different rates of seeding were as follows: One bushel of seed per acre yielded 24.65 bu.; $1\frac{1}{2}$ bu., 27.87 bu.; 2 bu., 29.12 bu.; $2\frac{1}{2}$ bu., 30.86 bu.; 3 bu., 30.43 bu.; $3\frac{1}{2}$ bu., 30.43 bu.; 4 bu., 32.79 bu.

Land subsoiled in the fall of 1895 yielded 52.56 bu. of oats per acre, while unsubsoiled land yielded 53.17 bu. "Subsoiling has almost invariably decreased the yield of wheat, corn, and oats on the college farm."

Fall-plowed and spring-plowed land was packed with Campbell's subsurface packer previous to seeding. Fall-plowed land packed once yielded at the rate of 29.37 bu., and the plats packed 3 times yielded at the rate of 29.34 bu. per acre. The unpacked fall-plowed land yielded 25.49 bu. per acre. Spring-plowed land packed once yielded at the rate of 27.87 bu. per acre, and plats packed 3 times yielded at the rate of 29.37 bu. per acre. Unpacked spring-plowed land yielded 22.24 bu. per acre.

Among the varieties tested for 7 years the so-called red varieties, such as Pedigreed Red Rust Proof, Red Rust Proof, and Red Georgia, have given the most satisfactory results in general.

With the use of "Ceres Pulver" the percentage of smut was reduced from 19.03 to 5.38.

Potatoes: Tests with fertilizers, M. A. SCOVELL (*Kentucky Sta. Bul.* 72, pp. 1-9, pl. 1).—Fertilizer tests were made on tenth-acre plats with nitrate of soda, acid phosphate, and muriate of potash applied singly, in twos, and the 3 substances together. Nitrate of soda and muriate of potash were applied at the rate of 160 lbs. per acre, and acid phosphate at the rate of 140 lbs. These amounts furnished 25.6 lbs. of nitrogen, 80 pounds of potash, and 57 lbs. phosphoric acid. Nitrate of soda and acid phosphate applied singly resulted in loss as compared with the check plats which received no fertilizer. The use of potash alone greatly increased the yield. Acid phosphate and muriate of potash applied together resulted in the best yield (109.6 bu.

per acre), while on the plot which received the application of the 3 fertilizing substances a yield of 109.4 bu. was obtained.

Sorghum: Its development as a commercial source of sugar, C. L. PENNY (*Delaware Sta. Bul. 39, pp. 23, figs. 3*).—The work of propagation commenced in 1894 was continued in 1897. Fields of sorghum were grown for the station on 2 private farms—at Cape Charles, Virginia, and Harbeson, Delaware. At the first place the varieties McLean and Amber were grown, and on the other farm the same 2 varieties with Colman and Frame New in addition. The stalks at different cuttings were sent to the station for analysis and the determination of other data. During the season more than 2,800 stalks were examined individually. The results are tabulated and discussed at considerable length.

In 1897 the percentage of sugar in the juice of Frame New ranged from 6.31 to 15.93 and averaged 11.98; that of Colman ranged from 10.16 to 17.84 and averaged 14.62; that of McLean grown at Harbeson ranged from 10.71 to 17.35 and averaged 15.20; the same variety grown at Cape Charles ranged from 6.69 to 19.05 and averaged 15.24; the Amber grown at Harbeson ranged from 8.30 to 19.19 and averaged 15.74; and the same variety grown at Cape Charles ranged from 10.09 to 20.50 and averaged 18.15.

A formula for calculating the quantity of sugar which can be manufactured from a ton of cane is worked out, which is as follows: "If the percentage of sugar in the juice be diminished by 0.9 per cent and the remainder be multiplied by the coefficient of purity, regarded as a fraction, the product will express the pounds of pure sugar actually to be crystallized from 100 lbs. of stripped and topped cane."

The results of experiments with sorghum at the station and at other stations are summarized in a table.

"There has been within the period of 10 years, from 1888 to 1897, an undoubted improvement in the cane, so that within that time the same variety, so called, has varied more than have different varieties at the same time. There must, of course, be differences of season and of soil more or less favoring or hindering a good crop, yet despite these there has been an unquestionable rise in the quality of the cane, and this must be attributed to judicious selection of seed for propagation."

A diagram is given showing the probable amount of sugar which can be crystallized from a ton of stripped and topped cane of Amber, McLean, and mixed crops grown under different conditions, indicating that "the several varieties, when compared on the basis of yield of crystallized sugar, show much greater differences than on the basis of sugar content. While on the latter basis the extremes are about as 3 to 1, on the former they are about as $5\frac{1}{2}$ to 1. This, as has been explained, is due to the fact that the proportion of sugar crystallized varies approximately as the purity of the juice, and, secondly, that the purity usually rises and falls with the sugar content."

The selection of seed for propagation, and the various factors which

are to be taken into account in the improvement of sorghum for sugar-making purposes are discussed at some length.

“The question of interval of planting as affecting tonnage per acre, and possibly as affecting in less degree sugar content, calls most urgently for thorough study. It is impossible to know without extensive and intelligently planned experiments exactly what may be expected as the maximum yield of both cane and of sugar. Estimates may be based on what has been done, but with cane as far improved as are these present crops over certain former ones, new experiments specially directed to this end must give valuable and much needed information.”

Sugar beets, J. T. WILLARD (*Kansas Sta. Bul. 78, pp. 65-80*).—This is a report on the cooperative culture experiments with sugar beets in 1897. Two hundred pounds of seed was distributed to 393 farmers and of these 156 sent samples for examination. The results of analyses are tabulated. The beet-sugar industry in its relation to the State is discussed, and directions given for growing sugar beets.

The average results deduced from the samples analyzed were as follows: Gross weight per beet, 1.51 lbs.; net weight, 1.09 lbs.; specific gravity of juice, 1.064; total solids in the juice, 15.52 per cent; sugar in the juice, 11.88 per cent; coefficient of purity, 76.1.

Sugar-beet investigations in 1897, A. D. SELBY and L. M. BLOOMFIELD (*Ohio Sta. Bul. 90, pp. 123-162, maps 6*).—This bulletin contains a detailed tabulation of cooperative culture experiments with the sugar beet in 1897. Maps are given showing the average rainfall and the average isotherms of the State for 15 years for June, July, and August; for these 3 months and September combined; and for September alone. Suggestions concerning beet-sugar factories and cultural methods are noted. The average results of analyses for the entire State show a sugar content of 14 per cent in the juice and a coefficient of purity of 78.7. It was found that in general the sugar content and purity of samples taken at different dates increased as the season advanced. Beets grown on clay soils were richer in sugar than beets grown in black loam or sandy soils. Samples grown on muck lands were especially poor in quality.

Wyoming sugar beets, E. E. SLOSSON and B. C. BUFFUM (*Wyoming Sta. Bul. 36, pp. 189-205*).—In this bulletin the results of experiments in sugar-beet culture for the years 1891 to 1897, inclusive, are reported in tables. The earlier experiments were made by the station on 5 experimental farms located in different parts of the State, and the later ones by a number of farmers throughout the State. The average results obtained on the experimental farms are given in the following table:

Comparative table showing results of sugar-beet culture on the experiment farms from 1891 to 1897, inclusive.

Experiment farm.	Average yield per acre.		Average purity.
	Tons.	Per cent.	
Lander.....	19.24	15.25	81.01
Laramie.....	5.09	13.26	75.50
Sheridan.....	13.25	18.36	83.93
Sundance.....	4.50	14.76	75.34
Wheatland.....	9.61	17.85	85.20

"The region about Sundance, when irrigation is not possible, and the elevated plateau . . . represented by Laramie, do not give satisfactory results. . . ."

"According to our experience, the alkali in this State, which consists chiefly of sodium and magnesium sulphate, does not interfere with the growth of the beets or perceptibly impair their quality. Good crops of satisfactory richness have many times been grown in ground strongly impregnated with soluble salts, and in 1897 an experiment bearing directly on this point was carried out."

The results were as follows:

Sugar beets grown on alkali and ordinary soils.

	Yield per acre.		Purity.
	Tons.	Per cent.	
Alkali land.....	7.2	19.0	89.2
Good land, subsoiled.....	6.4	19.7	88.2
Good land, not subsoiled.....	5.8	20.3	92.7

The sugar-beet industry is discussed in general and notes given on the method of cultivation.

Cane, sirup, and sugar, H. E. STOCKBRIDGE (*Florida Sta. Bul. 41, pp. 47, pl. 1, figs. 1*).—This is a popular discussion of sugar-cane culture and the manufacture of sirup and sugar from cane. The following subjects are considered in short notes: Soil conditions, preparation of the land, fertilizing the crop, planting the cane, cultivating, harvesting, and preserving seed cane.

Analyses were made of 3 varieties of cane on different dates to test the effect of the time of harvesting upon the yield of sugar. The results are shown in the following table:

Sugar content of cane on different dates.

	Cut Nov. 20.	Cut Nov. 30.	Cut Dec. 10.
	Per cent.	Per cent.	Per cent.
Red cane.....	14.22	15.34	15.60
Green cane.....	10.19	11.41	15.15
Ribbon cane.....		10.34	12.36

From a consideration of the relative profits from sirup making and sugar making the conclusion is drawn that sugar cane "is more profita-

ble when converted into sirup than when manufactured into sugar; still the combination of the two is commendable, at least to the extent of supplying home demand. . . . The sugar-cane crop on a purely commercial basis can be made one of the most profitable resources of the Florida farmer, aside from the mere advantage of domestic independence." The manufacture of sirup on the farm and the use of Spanish moss for clarifying are described.

Practical chemistry of soils and crops, G. L. HOLTZ and J. FIELDS (*Oklahoma Sta. Bul.* 22, pp. 1-10).—General suggestions on crops and soils, giving the amount of the elements of fertility removed from the soil by crops of wheat, oats, corn, Kafir corn, cotton, and castor beans.

Fertilizer experiments and variety tests with barley, C. KRAUS and G. LUFF (*Fühling's Landw. Ztg.*, 47 (1898), No. 13, pp. 487-493).

Notes on the culture of winter barley (*Deut. Landw. Presse*, 25 (1898), No. 59, p. 656).—Notes on the culture and harvesting of winter barley.

Practical notes on growing and harvesting barley for brewing purposes, A. EMMERLING (*Landw. Wechnbl. Schleswig-Holstein*, 48 (1898), No. 29, pp. 502-504).

Malting barley (*Queensland Agr. Jour.*, 2 (1898), No. 6, pp. 440-443).—Hints on the successful cultivation of barley for malting purposes.

The black Mauritius bean, A. H. BENSON (*Queensland Agr. Jour.*, 3 (1898), No. 2, pp. 151, 152, pls. 2).—A short description of the plant and notes on the preparation of the soil, method of planting, and use of the crop are given. This legume is closely related to the velvet bean.

Crimson clover, F. E. EMERY (*North Carolina Sta. Bul.* 145, pp. 231-247).—A discussion of the experiments with crimson clover at the station and the cooperative experiments carried on throughout the State. A digestion experiment with feeding crimson clover hay to a goat and a sheep is reported. Notes are given on the dangers of feeding overripe crimson clover hay and on the introduction of crimson clover into the State.

Medicago maculata and M. denticulata for fodder and green manuring, F. SPIEGEL (*Deut. Landw. Presse*, 25 (1898), No. 45, p. 494).—The value of these legumes is briefly mentioned and the method of treating the seed before sowing described.

Brabant clover, H. BICHEL (*Landmansblade*, 31 (1898), No. 4, pp. 38-40; *Märkfrökontoret 25 Aasher.*, 1897, pp. 18-20).—This clover, an annual, originated in Brabant, Holland, and is there grown mainly for soiling purposes. There are two varieties, one small seeded, the other large seeded, differing in the size of the seed and herbage. The large-seeded variety produces the heavier yields of fodder. This variety has been grown in Denmark in an experimental way and has given promising results.

A variety test of cotton, 1893, F. E. EMERY (*North Carolina Sta. Bul.* 146, pp. 254-258).—Fourteen varieties, including the Egyptian varieties Afifi and Bamia, were tested. The highest percentage of lint was obtained from Peterkin, King No. 1, and Shine Early Prolific, which varieties, with King No. 2, also produced the largest yields of lint.

A small variety test of cowpeas, F. E. EMERY (*North Carolina Sta. Bul.* 146, pp. 251, 252).—Six varieties of cowpeas were tested. The Black cowpea ripened earliest and the Unknown variety produced the largest yield of dry peas. The peas were planted July 3, and on September 22 the Black variety had ripened and its leaves fallen.

Growing grass and other forage crops for seed (*Braunsch. Landw. Ztg.*, 66 (1898), No. 33, pp. 139, 140).

Notes on the seeding of grass land, W. T. HALL (*Agr. Students' Gaz.*, n. ser., 9 (1898), No. 1, pp. 4-8).—A report on the percentage of different grasses in pastures 4 and 5 years after seeding them down.

Setaria and its culture, P. MIKHUYEV (*Selsk. Khoz. i Lycesov.*, 187 (1897), May, pp. 347-380).

Harvesting lupines and oil-yielding crops, J. KÜHN (*Deut. Landw. Presse*, 25 (1898), No. 56, pp. 623, 624).—A discussion of the methods of harvesting lupines and crops of rape and beets grown for the seed.

Oil-yielding crops and lupines, H. LEHNERT (*Deut. Landw. Presse*, 25 (1898), No. 75, p. 804).—The methods of culture and harvesting are briefly noted.

Culture and use of white mustard (*Sinapis alba*) (*Deut. Landw. Presse*, 25 (1898), No. 66, p. 723).

Growing winter barley, J. H. MANSOLT (*Deut. Landw. Presse*, 25 (1898), No. 65, p. 711).—Notes on cultivating and harvesting winter barley.

Culture experiments with winter oats, SCHLACHT (*Deut. Landw. Presse*, 25 (1898), No. 64, p. 704).—A discussion of results of experiments with English varieties of winter oats. The varieties are not yet adapted to the climatic conditions of Germany.

Some experiments with potatoes, F. E. EMERY (*North Carolina Sta. Bul.* 116, pp. 258-263).—Comparisons were made of deep and shallow culture, early and late planting, and different rates of seeding. Deep planting with level culture yielded 30.25 bu. more per acre than shallow planting with hilled culture; the early-planted plot yielded at the rate of 108.1 bu. more per acre than the late-planted plot; and seeding at the rate of 24 bu. per acre resulted in better yields than seeding at the rate of 12 and 18 bu. per acre.

Planting potatoes and their fertilizer requirements, M. FISCHER (*Fühlings' Landw. Ztg.*, 47 (1898), No. 9, pp. 350-356).—A discussion of experiments.

Wheat testing—description of mill, F. B. GUTHRIE (*Agr. Gaz. New South Wales*, 9 (1898), pt. 7, pp. 713-716, pl. 1).—A description of a mill for testing small samples of wheat. The advantages of the mill in testing the milling qualities of wheat from experimental plats and in judging wheats are pointed out.

Test of effect of chemical manure and cotton-seed meal on the germination of wheat, F. E. EMERY (*North Carolina Sta. Bul.* 116, pp. 253-254).—To a number of wheat plats chemical manures and cotton-seed meal were applied at the time of sowing the grain. On some plats the cotton-seed meal was worked into the soil before sowing and on others it was put on top of the covered rows. The results indicated that cotton-seed meal under the wheat injuriously affected its growth. "It is believed that the oily character of the meal interferes materially with the rising of water in the soil by capillarity" and that in this way an application of cotton-seed meal, especially when but recently made, interferes with germination and growth.

Heine bearded squarehead wheat (*Deut. Landw. Presse*, 25 (1898), No. 75, p. 807, fig. 1).—A description of the variety and its history are given.

Relations between the color of the grain, the composition, and the form of the heads and stems of rye, M. FISCHER (*Fühlings' Landw. Ztg.*, 47 (1898), No. 13, pp. 504-517, pls. 4).—The results of experiments in breeding rye are discussed with reference to the transmission of the above-mentioned factors.

The lodging of grain, L. LEHMANN (*Deut. Landw. Presse*, 25 (1898), No. 64, p. 705).—Notes on methods which tend to prevent the lodging of grain.

Storage of grain, O. BÖHM (*Die Kornhäuser. Stuttgart: J. H. Cotta's Successor*, 1898).—A study of the organization of the grain trade in America, India, Russia, and Germany, with special reference to the systems of storing grain in the different countries.

Plants best adapted for litter, F. G. STEBLER (*Die besten Streuepflanzen. Bern: K. J. Wyss, 1898*).

Experiments in tobacco culture in 1895 and 1896, N. PASSERINI (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 4, ser., 21 (1898), No. 1, pp. 43-59).—The experiments consisted of fertilizer and variety tests with tobacco. The varieties tested were Kentucky Burley, Seed Leaf, Havana, Sumatra, Brazilian Exotic, Virginia Bright, Aya-Suluk, Malacca, and Singapore. The results are tabulated and discussed in detail.

Cooperative experiments made by the Ohio Agricultural Students' Union in 1896, L. M. BLOOMFIELD and J. S. HIXE (*Ohio Sta. Bul.* 88, pp. 69-97).—This bulletin describes the purpose of the organization, outlines the plan of the experiments, and reports the results of various experiments with corn and potatoes. The results of fertilizer tests are tabulated and the manner in which the experiments were conducted is described. The results of experiments with corrosive sublimate and flowers of sulphur for the prevention of potato scab, and of variety and culture tests with potatoes are reported.

HORTICULTURE.

Asparagus, F. W. CARD (*Nebraska Farmer*, 26 (1898), No. 25, p. 554).—The author reports the results of experiments with asparagus at the Nebraska Station. Salt as a fertilizer was found to have no beneficial effect and to be injurious when used in considerable quantities. Deep setting of asparagus is briefly discussed and the arguments usually given in favor of it are noted. To test the matter, 100 plants each of Donald Elmira and Palmetto varieties were set in 1894, one-half of each variety being placed from 8 to 10 in. deep and one-half from 3 to 4 in. deep. The results are given as follows: "The first difference to appear between these depths of planting was the influence upon earliness. Those plants set shallow appeared decidedly in advance of the ones planted deep, and this difference was not only evident the first year but has continued in succeeding years. Later in the season comparatively little difference in the vigor of the plants was observed, if any difference existing being in favor of the shallow-set plants."

Growing melons in the North, F. W. RANE (*New Hampshire Sta. Bul.* 52, pp. 19-70, figs. 6).—Suggestions concerning the culture of muskmelons in New Hampshire are given and a test of 72 varieties is reported. The data are given in tables accompanied by descriptive notes. The fruits of the different varieties are illustrated. The characteristics of the varieties as compiled from various catalogues are given in tabular form. The small-sized varieties proved more productive than the larger ones. The varieties having the best flavor were as follows: *Small*—Captain, No. 88, Newport, Golden Netted Gem, Earliest Ripe, Rose Gem, Jenny Lind, Shippers' Delight; *medium*—Perfected Delmonico, Pineapple, Extra Early Cantaloupe, Satisfaction, Skillman Fine-netted, Improved Jenny, Jersey Belle, Ivy Gem, Banquet, Market, Netted Nutmeg; *large*—Sill Hybrid, Tip Top, Ironclad, Miller Cream, Delmonico, Long Island Beauty, Six Oaks Cantaloupe, Surprise; *extra large*—Lone Star, Long Yellow, Triumph.

Tomatoes, J. S. ROBINSON (*Maryland Sta. Bul.* 54, pp. 117-134).—The bulletin reports variety tests of tomatoes and experiments in the use of Bordeaux mixture for tomato-leaf blight. In 1896, 20 plants each of 30 varieties, and in 1897, 12 plants each of 19 varieties were grown. One-half of the plants of each variety were sprayed with Bordeaux mixture, the other half being left unsprayed. The first year the plants

were sprayed 4 times and the next year 3 times. Tables are given showing the dates of picking, the weight of fruit at each picking, and the computed yield per acre for both the sprayed and unsprayed plants of each variety.

In regard to varieties the author says: "The varieties giving the largest early yields are Early Ruby, Potato Leaf, Prize Taker, Autocrat, and Canada Victor. The best varieties for main crop trucking are Paragon, Prize Taker, Perfection, World's Fair, and Climax. The best varieties for the canning trade are Royal Red, Queen, Stone, Paragon, and Matchless. The best variety for late market or family use is the Buckeye State." The first 4 sprayings increased the yield of ripe fruit of all but one variety in 1896 and of all but 3 varieties in 1897, and, taking account of the green fruit at the end of the season, spraying increased the yield in every case. In 1896 the average yield of the sprayed plants was at the rate of 9.52 tons per acre and of unsprayed plants 6.98 tons per acre. In 1897 yields of sprayed and unsprayed plants were at the rate of 10.26 and 8.11 tons per acre, respectively. It was found that infection of the blight may take place through the agency of insects. Some Colorado potato beetles that were feeding on blighted potatoes were placed on isolated and protected tomato plants, other plants being kept as checks. The plants on which the beetles were placed blighted, while the check plants showed no evidence of the disease.

Miscellaneous fruit notes, S. C. MASON and W. L. HALL (*Kansas Sta. Bul.* 73, pp. 181-193).—Notes are given on 20 of Munson's hybrid grapes. In summarizing the notes the author says:

"All the Post Oak hybrids are tender in our climate and need winter covering. All are vigorous growers except the Triumph hybrid, and all are late in blooming and in ripening of fruit. Blood, Sweetey, and Letoney give us a delicious juice for canning, and doubtless would make a fine wine; Carman is a very fair table grape; Texas Highland is a better, but does not bear well. . . .

"From this brief glance at all of these hybrids we may fairly infer, it seems to me, that the pistillate parent exercises a stronger control over the character of the vine than does the pollen-bearing parent, while the predominating influence of the male (or pollen-bearing) parent can most often be detected in the fruit; and further, that the strong tendency toward tenderness from a *Vitis vinifera* cross is not escaped in the third generation."

Tests of the Mariana plum indicated that it can be used with good results as a stock for grafting the varieties of American, Japanese, and European plums. Apricots grafted on the Mariana stock made a vigorous growth, but there was an almost total lack of continuity in grain of wood of stock and scion. A longitudinal section of a 6-in. tree trunk showed a sharply drawn line rising a little from the center to the outside. "Toward this line of separation the wood grain from each side made a sharp curve inward, becoming parallel with it. A section $\frac{1}{4}$ in. in thickness was readily broken with slight pressure, breaking sharply on this line across the entire section, except a small portion at the center."

A test of the relative value of peach and Myrobalan plums as stocks for peaches resulted decidedly in favor of the peach stocks. The trees grafted on plum stocks were not as strong growers as the others, began early to show signs of failing, and had trunks with decided enlargements just above the stock.

Notes are given on a number of Russian fruits, none of which are recommended for growth in Kansas.

Dendrolene applied to the trunks of peach trees for about a foot just above the ground damaged the trees in all cases, some of the trees being killed.

In germinating a quantity of peach pits it was noticed that a number of them contained 2 embryos, 2 seedlings forming instead of 1. These seedlings were fruited for 3 years and observed closely to determine whether the 2 trees from one pit would differ from each other as much as seedlings ordinarily do. The author says:

"Of the distinctness of each tree as a variety there can be no question, the trees of some pairs being more distinct from each other than from trees in other pairs. In other cases the 2 trees were so nearly alike as to call for an inspection of minute details of leaf and gland in order to distinguish them. The resemblance to the variety from which the seed was produced was very marked, and especially in the case of the seedlings from Hale Early."

Varieties of pears and peaches. G. COOTE (*Oregon Sta. Bul. 52, pp. 8-16, figs. 9*).—Descriptive notes are given on several varieties of pears, with outline drawings of the fruits of each.

Notes are given on the leaf curl of peaches (*Eroascus deformans*). To determine whether the disease was caused by climatic changes, badly affected trees of 3 varieties were transplanted in the fall of 1893 to half-barrels in a greenhouse, the temperature of which did not fall below freezing. The trees were placed outdoors during the following summer. They grew well and showed no signs of disease. The next fall the trees were returned to the greenhouse. The following season they were perfectly healthy and blossomed and fruited well. Buds from diseased trees from the orchard were set in healthy greenhouse trees. The buds grew well, only the first leaves being affected. In the next fall the trees were planted in the orchard and the following spring were very severely attacked by the disease. For preventing leaf curl the author believes that a mixture of lime, sulphur, and salt, used to spray the trees just before the buds open, is beneficial.

Flower seed growing in America. W. W. TRACY (*Gardening, 6 (1898), No. 136, pp. 243, 244*).—In discussing the improvement of the sweet pea in America the author says: "The Extra Early Blanch Ferry was not the result of the selections of the earliest flowers, but it was developed on the theory that the time (from the sowing of the seed) of the plant coming into flower was quite as largely affected by conditions of growth as by constitutional tendency, but that the period in the development of the plant when it first showed bloom was more a matter of constitutional tendency than of growth conditions. Accordingly, in

breeding for early flowering, plants which produced flowers from the lowest nodes rather than those which first showed flowers were selected, and the results showed the correctness of the theory. It seems to me that what Americans have done in the development of this flower suggests possibilities with others and that we ought to look forward to the production of our own flower seeds of all kinds."

Adherence to type of seed breeding, W. W. TRACY (*Gardening*, 6 (1898), No. 138, pp. 282, 283).—The author notes some of his experience in breeding vegetables and flowers to illustrate the value of first forming an ideal and of then adhering to it strictly. He says: "The highest quality and most practically valuable seed of a variety is not that which from a large planting will produce a few superlative plants but that from which the largest proportion of the entire product will be of fine type. Uniformity of product is really the most important object of seed breeding, and to secure it we must have first a clear conception of just what in every particular an ideal plant of the variety should be, and secondly we must adhere rigidly to that ideal in our selection of breeders from year to year, and that we may do so it is essential that we have on record a full, minute, and accurate description of the ideal plant we are working to produce and select such plants and such only for breeders, rejecting those that differ from the ideal in any way even if the difference is of itself an improvement. . . . An intimate acquaintance with most of the stocks of vegetable and flower seeds in common use convinces me that the greatest horticultural need of the age is clearly defined ideas of just what ideal plants of the different varieties propagated by seed should be and a closer adherence by seed growers to such ideals in selecting stock."

Report of horticultural department, C. B. WALDRON (*North Dakota Sta. Rpt.* 1897, pp. 25; 26).—Experiments with celery and cauliflower are outlined. No results were secured on account of destruction of the plants by cutworms. A destructive disease of raspberries is noted.

Marketing fruit, M. CRAIG (*Oregon Sta. Bul.* 51, pp. 8).—Suggestions on picking, packing, and marketing fruit.

The export of our tender fruit, J. W. ROBERTSON (*Canad. Hort.*, 21 (1898), No. 8, pp. 303-307, figs. 2).—A reprint from the report of the Commissioner of Agriculture [Canada] on experimental fruit shipments to Great Britain. The picking, packing, and shipping of fruit, and the construction of fruit packages, are briefly discussed. Tables show the amount of various fruits imported by Great Britain from different countries.

Influence of the honey bee on the fruit crop, L. D. STILSON (*Nebraska Farmer*, 26 (1898), No. 35, p. 554).—A popular article read before the Nebraska and Southwestern Iowa Horticultural Societies.

Chemical fertilizers for garden and orchard, R. DUMONT (*Prog. Agr. et Vit.*, 30 (1898), No. 29, pp. 78-82).

The use of fertilizers in horticulture, A. HÉBERT and G. TRUFFAUT (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 25, pp. 1831-1834).

The propagation of plants by cuttings (*Wiener Illus. Gart. Ztg.*, 23 (1898), No. 8-9, pp. 295-299).—A popular article on cuttage.

Selection in its relation to horticulture, C. L. ALLEN (*Eastern New York Hort.*, 2 (1898), No. 1, pp. 11, 12).

Notes on horticultural nomenclature, F. A. WAUGH (*New York: American Gardening*, 1898, pp. 26).—This consists of six essays under the following heads: General problems, Pomological rules, The names of garden vegetables, Examples of scientific methods, Property rights in names, and Hints on naming. The essays are intended as suggestions for nurserymen, fruit growers, gardeners, seed growers, plant breeders, and students of horticulture. The first five essays were first published in *Country Gentleman*, vol. 63.

Fruit evaporation, H. E. BOSCH (*California Fruit Grower*, 23 (1898), No. 3, p. 4).

Home canning of fruit, Mrs. W. F. JENKINS (*Nebraska Hort. Soc. Rpt.* 1896, pp. 263, 264).—Directions are given for canning strawberries, cherries, plums, apples, peaches, pears, and sweet corn.

Thinning fruit (*Canad. Hort.*, 21 (1898), No. 7, pp. 264-266, fig. 1).—A reprint from U. S. Dept. Agr. Farmers' Bulletin 73.

Forcing vegetables, A. HERRINGTON (*Amer. Gard.*, 19 (1898), No. 196, pp. 667, 668).—Notes on the forcing of cauldlowers, beets, onions, carrots, radishes, lettuce, rhubarb, asparagus, and chicory.

Originating new vegetables, A. LOW (*Gardening*, 6 (1898), No. 138, pp. 280, 281).—A paper read before the Massachusetts Horticultural Society.

Sweet corn for New Hampshire, F. W. RANE (*New Hampshire Sta. Bul.* 51, pp. 33-46, figs. 3).—A test of 11 varieties of sweet corn is reported. The data obtained are recorded in notes and tables showing earliness, quality, yield, size, prevalence of smut, etc. Illustrations are given showing stalks, whole ears, and cross sections of ears of the different varieties. The following varieties gave the best results: *Extra early*—Extra Early Beverly, Eastman Early, Early Fordhook, First of All, White Cob; *early*—Crosby Early; *medium*—Asylum Sugar, First Crop, Early Essex, Squantum; *late*—Hance Early, Triumph Sugar, Stowell Evergreen, Country Gentleman.

Lettuce growing in Florida, P. F. WILSON (*Florida Farmer and Fruit Grower*, n. ser., 10 (1898), No. 30, p. 630).

A study of lettuces, W. F. MASSEY (*North Carolina Sta. Bul.* 147, pp. 267-271).—The bulletin gives suggestions on the winter culture of lettuce and reports a variety test of lettuce. Notes are given on 31 varieties tested at the station.

How to grow mushrooms, D. FRASER (*Amer. Gard.*, 19 (1898), No. 192, Sup., pp. 1, 2).—A prize essay on mushroom culture.

Tomato growing, E. B. VOORHEES (*U. S. Dept. Agr. Farmers' Bul.* 76, pp. 29).—The bulletin treats of tomato culture for the early market, for the medium and late crops, for canneries, and in the greenhouse; discusses the selection of varieties, growing young plants, selection and preparation of soil, manures and fertilizers, setting and training plants, cultivation, pollination, cost, yield and value of crops, markets and prices, etc. The insect enemies of the tomato are briefly considered. Notes are given on fungus diseases of tomatoes by B. D. Halstead.

Advantages of cultivation (*California Fruit Grower*, 23 (1898), No. 12, p. 1, figs. 3).—The article is from California Station Bulletin 121 and shows the benefits derived from cultivating orchards.

Apple culture near London, J. HUDSON (*Garden*, 54 (1898), No. 1395, pp. 120-122).—Notes on culture and varieties of apples suitable to the locality of London.

Some principles in Delaware apple culture, G. H. POWELL (*Delaware Sta. Bul.* 38, pp. 20, figs. 9).—This is a popular bulletin disussing the statistics of the apple industry in Delaware, and giving practical suggestions on apple growing in the State. The lack of prominence of apple culture is thought to be due to the selection of varieties not adapted to the conditions of the region. The principles on which the selection of varieties should be based are noted. A number of varieties of apples are described.

The principles and practice of pruning, W. C. WORSDELL (*Gard. Chron.*, 3. ser., 24 (1898), No. 608, pp. 133, 134).

Gumming of stone fruits, S. A. BEACH (*Amer. Gard.*, 19 (1898), No. 192, p. 606).—A brief résumé of what is known regarding the cause of the gumming of stone fruits.

Grafting the plum and cherry, N. E. HANSEN (*Nebraska Hort. Soc. Rpt.* 1895, pp. 179-184, fig. 1).—The propagation of cherries and plums by grafting is described.

Classification of varieties of peacher, R. H. PRICE (*Amer. Gard.*, 19 (1898), No. 189, p. 560).—A paper read before the American Pomological Society.

Edible fruits indigenous to Queensland, F. M. BAILEY (*Queensland Agr. Jour.*, 2 (1898), No. 6, pp. 471, 472, pl. 1).—Descriptions are given of *Davidsonia pruriens* and *Eugenia eucalyptoides*.

Currant bushes failing to bear fruit, A. P. AITKIN (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 10 (1898), pp. 293-294).—The author reports analyses of the soil of an orchard to determine the cause of the failure of currants to fruit. The cause was not ascertained.

Strawberries, C. W. MATTHEWS (*Kentucky Sta. Bul.* 73, pp. 27-42).—The bulletin gives directions for the culture of strawberries and descriptive notes on 65 varieties based on work at the station and on the experience of some 130 strawberry growers of the State. The favorite market varieties for Kentucky in order of merit are Bubach, Haverland, Gandy, Crescent, Michel, and Warfield.

Growing strawberries by irrigation, J. W. STEVENSON (*Nebraska Hort. Soc. Rpt.* 1896, pp. 17-21).—The author's experience in the use of windmills for irrigating strawberries is given.

Judging or scoring fruit, W. R. LAZENBY (*Country Gent.*, 63 (1898), No. 279, p. 688).—Suggested scales of points for judging apples, grapes, strawberries, and tomatoes are given and the scale of points for apples is discussed in detail.

Grape pruning, E. H. RAINFORD (*Queensland Agr. Jour.*, 2 (1898), No. 6, pp. 462-470, pl. 1, figs. 11).—A popular article giving directions for pruning grapes.

Stocks for grafting grapes, P. GERVAIS (*Prog. Agr. et Vit.*, 30 (1898), No. 38, pp. 331-341).—This is a report presented to the Congrès viticole de Lyon and to the Congrès international d'agriculture de Lausanne. The use of American grapes (*Vitis rupestris*, *V. riparia*, and *V. berlandieri*), their hybrids and varieties, and hybrids between them and *V. vinifera* as stocks resistant to phylloxera are discussed.

Notes on self-fertility of cultivated grapes, S. A. BEACH (*Amer. Gard.*, 19 (1898), No. 196, pp. 606, 607, fig. 1).—A paper read before the Society for the Promotion of Agricultural Science. The data included in this article have previously appeared in the New York State Station reports (E. S. R., 9, p. 52).

Objects and methods of crossing the grape, N. E. HANSEN (*Nebraska Hort. Soc. Rpt.* 1895, pp. 27-30).

A new departure in grape hybrids (*Amer. Gard.*, 19 (1898), No. 196, p. 609, figs. 2).—The production of three new grapes, La Salle, San Jacinto, and De Soto, all hybrids of Seppernong, is noted. The varieties are described and San Jacinto and De Soto are figured.

Vineyard management, F. W. CARD (*Nebraska Hort. Soc. Rpt.* 1895, pp. 33-50, figs. 7).

Grape growing and wine making in the Caucasus, VIII (*Tiflis: Government of Tiflis*, 1897, pp. 176; *abs. in Selsk. Khoz. i Lycov.*, 188 (1898), Jan., pp. 239, 240).

The almond and its varieties (*Garden*, 54 (1898), No. 1395, pp. 122, 123, pl. 1).—Brief notes.

The cultivation of the hazelnut, G. COOTE (*Oregon Sta. Bul.* 52, pp. 3-7, pl. 1, figs. 2).

Growing the pecan, S. POWERS (*Country Gent.*, 63 (1898), No. 2377, p. 653).—Notes on pecan culture.

Ornamenting home grounds, W. M. MUNSON (*Maine Sta. Bul.* 42, pp. 8).—The bulletin gives suggestions on making lawns and flower gardens, the planting and

arrangement of trees and shrubs, the choice of plants, etc. A list of native trees and shrubs valuable for planting is added.

The pruning of ornamental plants (*Wicner Illus. Gart. Ztg.*, 23 (1898), No. 8-9, pp. 292-294).—The main principles of pruning ornamental plants are said to be to cut back weak growths to a few buds and stronger growths only a little, and to prune early blooming kinds of plants in summer after blooming and late blooming kinds in fall, winter, or early spring. A list of plants is given and the season in which they should be pruned is indicated.

Showy annuals, F. BRUNTON (*Canad. Hort.*, 21 (1898), No. 7, pp. 274-277).—Notes on the culture of a number of annual flowering plants useful for mixed borders.

The species of Camellia (*Garden*, 54 (1898), No. 1401, pp. 242, 243, pl. 1, figs. 2).—Notes on the ornamental value of camellias and descriptions of several species.

Cannas in 1898, D. ZIRNGEBEL (*Florists' Exchange*, 10 (1898), No. 40, p. 939).—Lists of cannas regarded as best by the author are given, with brief notes on their value for ornamental purposes.

Growing roses under glass, N. BUTTERBACH (*Amer. Gard.*, 19 (1898), No. 197, *Sup.*, pp. 1, 2).—A prize paper on rose culture under glass.

Growing roses under glass, T. HARRISON (*Amer. Gard.*, 19 (1898), No. 197, *Sup.*, pp. 2, 3).—A prize essay on rose culture under glass.

Violets and how to grow them, F. THAWITE (*Amer. Gard.*, 19 (1898), No. 188, *Sup.*, pp. 10, 11).

Improvement in varieties and improvement in cultural methods as exemplified in high grade flowers, E. G. HILL (*New England Florist*, 4 (1898), No. 25, pp. 291, 292; *Florists' Exchange*, 10 (1898), No. 34, pp. 804, 805; *Amer. Florist*, 14 (1898), No. 533, pp. 90-92).—A paper read before the Society of American Florists and Ornamental Horticulturists.

FORESTRY.

Woods adapted for the manufacture of paper pulp, F. ROTH (*Forester*, 1 (1898), No. 3, pp. 60, 62, 63).—The author states that according to a canvass made in 1888 by the Division of Forestry of this Department, of the 240 wood-pulp mills then reporting nearly half used nothing but spruce timber, about 25 per cent used spruce and poplar, and 6 per cent used poplar alone, the others using a variety of woods, such as pine, hemlock, basswood, balsam, cypress, birch, maple, beech, buckeye, and gum. Considering the rapid increase of the wood-pulp industry and the reduction of the supply, the question naturally arises as to what shall prove a substitute for the spruce. The characteristics of different woods and their relative value for use in the manufacture of pulp are referred to, and the author in concluding states that—

“From the standpoint of a supply, it is quite probable that the conifers will be in the future, as they have been in the past, the main pulp woods of our country. They are still quite abundant and any step toward protection and reforestation, such as may naturally be expected in the near future, will insure new supplies by the time the present stands are cut.

“In the New England States and the East generally spruce will probably continue, aided by hemlock and possibly by second-growth pine. In the Lake Region, hemlock, together with scattered spruce and balsam, will furnish pulp wood for a considerable period and when this is exhausted the pine forests may be expected to take their place. Of the hard woods only the basswood appears sufficiently abundant to warrant its consideration as a source of long time supply.

“In the South coniferous material is found in the spruce, white pine, and hemlock

of the mountains and still more in the vast bodies of hard pines (loblolly, short leaf, long leaf, etc.). When the chemical processes are adapted to the use of these resinous hard pines, the South will be in position to support a great number of pulp mills.

"Western United States, with their extensive forests of conifers, are in good position to supply large quantities of pulp, but the different kinds of spruce, fir, etc., have not been sufficiently studied to warrant any detailed statement."

The sustained yield of spruce lands, G. PINCHOT (*Forester*, 4 (1898), No. 3, pp. 56-59).—This paper, which is an abstract of an address read before the American Paper and Pulp Association, February, 1898, reviews the spruce growth of the Ne-ha-sa-ne Park in the Adirondack forests. The abundant reproduction of spruce and its ability to survive under heavy shade are shown in the data given as to the number of trees in more than 1,000 acres of this park. The author has tabulated the number of trees on this area and it appears there are 314,000, of which 150,228 are 2 in. or more in diameter.

The rate of growth for the past 10 years, as shown by measurements of 300 trees which were of marketable size, ranging from 9 to 27 in. in diameter, shows that the mean annual growth is about 0.11 in.; or, on an average, that about 9 years is required to add 1 in. in diameter to a spruce tree after it has attained merchantable size. This rate of growth is considerably less than was originally supposed.

Financial returns of forest administration in Bavaria (*Forester*, 4 (1898), No. 3, pp. 61, 65).—The forest area of Bavaria is said to be about 34 per cent of the total area of the Kingdom. One third of this area is owned by the State, one-half by private owners, and the rest by villages and corporations. Since 1830 the State has spent about \$8,000,000 in acquiring additional forest property. Of the 6,200,000 acres of forest, about 46 per cent is stocked with spruce from which the lumber is usually harvested at an age of 120 years; 30 per cent is pine, mostly Scotch pine, and is largely used as firewood, generally being cut down at an age of 80 years or less; the rest is stocked with hard woods, mostly beech, which is allowed to grow to an age of about 120 years. Some white oak is grown, part of which is managed as tan-bark coppice, being cut every 15 to 25 years, while other trees are allowed to grow into large trees for which about 180 years are necessary in this region. The yield per acre is generally large, the State forest yielding on an average about 61 cu. ft. for every year's growth over the entire area, so there is an annual cut of about 120,000,000 cu. ft. of timber and firewood. The money returns of the Bavarian State forest are somewhat less than those of the forests in Saxony and Wurtemberg. This is said to be partially due to the prevalence of mountain lands which reduce the yield while increasing the cost of operations. Improved methods of administration, however, have increased the net revenue so that the income which in 1850 amounted to about \$1 per acre, is now \$1.92, the net income of the State amounting to about \$4,000,000 per year.

The conifers of China, L. BEISSNER (*Bul. Soc. Bot. Ital.*, 1898, No. 6, pp. 166-170).
Tilia cordata, E. G. BAKER (*Jour. Bot.* [London], 36 (1898), No. 128, pp. 318, 319).

An exact method for determining the season in which timber has been felled, P. I. RASHEVSKI (*Warsaw*, 1897, pp. 11; *abs. in Selsk. Khoz. i Lyesor.*, 187-1897), p. 146).—The author describes a method for determining by use of the microscope whether a given piece of timber was felled in summer or winter. The method is illustrated by drawings of microscopic sections of pine felled in different seasons.—P. FIREMAN.

SEEDS—WEEDS.

Heat of imbibition by seeds, G. MACLOSKEY (*Bul. Torrey Bot. Club*, 25 (1898), No. 5, pp. 272-274).—The author states that the explanation of the production of heat in germinating seeds by destructive metabolism is not sufficient to explain the rising of temperature or certain cases of germination which have occurred at very low temperatures. He reviews briefly the various opinions relative to the physics of imbibition, and describes a limited experiment in which dried peas with water were placed in a bottle and beside it a control bottle containing water, the initial temperature of the two being the same. In about an hour the temperature of the first bottle had increased about 1° C. over the check and remained about this much higher for 3 days, when the peas began to germinate.

In the second experiment, conducted in a somewhat similar manner, the author used dry split peas devoid of seed coat, without radicle or plumule, so there could be no germination. They absorbed water quickly and in a short time the temperature was 1° C. higher than that of the control bottle. This continued for 15 hours, by which time the seeds had become thoroughly saturated, when the temperature fell to that of the water in the other bottle. The author states that a difference of 1° C. will certainly not appear insignificant since the temperature of germinating peas was only 1.5° C. higher than the surrounding air, as determined by experiments of Sachs. No attempt was made to estimate quantitatively the amount of heat which was evolved.

The author believes that in the experiments cited by Uloth in 1871, in which seeds were found germinating in ice, while the initial heat may have been due to some external cause, after the seeds had become wet the heat produced by imbibition might have melted the ice to such an extent as to account for the germination.

The influence of X-rays on germination, MALDINEY and THOUVENIN (*Rev. Gén. Bot.*, 10, No. 111, pp. 81-86, pls. 2).—The authors briefly review the somewhat limited literature on this subject and give in some detail a series of interesting experiments in which the effect of X-rays on the germination of a number of seed was investigated. The seeds tested were millet, *Convolvulus arvensis*, and *Lepidium sativum*. The form of apparatus used is figured and described. Check seeds were protected from the action of the X-rays by means of leaden plates. From the results of the experiments the authors conclude that X-rays

hasten germination somewhat, and that they are without any influence on the production of chlorophyll in the seedlings.

Effect of different temperatures of water on the germination of olive seeds, N. PASSERINI (*Bul. Soc. Bot. Ital.*, 1898, No. 3, pp. 71-73).—After removing the pericarp from a number of olives the seeds of 8 lots were subjected for 10 minutes to the action of water of different temperatures, the initial temperature of which varied from 30 to 100° C. The seeds were then planted, and the germinations for 7 months are tabulated. It appears that the germination of the olive seeds was accelerated when they were treated with water heated to from 40 to 50°, and the maximum was reached at 70° C. When the water was hotter than 90° C. there was no germination, the seed having been killed.

The woolly mullein, H. GARMAN (*Kentucky Sta. Bul.* 70, pp. 99-107, pls. 2, map 1).—In continuation of his investigations (E. S. R., 9, p. 1024) on this weed (*Verbascum phlomoides*), the author describes its distribution and some of its characteristics. As now known, the woolly mullein has an uneven distribution over about 50 square miles, including portions of 4 counties. The main distribution seems to be along the Nolin River, and it is thought the weed was probably introduced originally somewhere near the headwaters of this stream. The effect on germination of soaking the seed of this plant was investigated by the Division of Botany of this Department, and a report given in the bulletin shows that an average of 73 per cent germinated after floating for 7 days in a bowl of water and 69 per cent after having been in water for 14 days: so that practically the seeds would not lose their vitality by being carried any ordinary distance down stream.

Notes are given on the history of this weed in Kentucky and on its distribution in Europe. It does not thrive in cultivated fields when these are properly cared for, but is chiefly a frequenter of roadsides, meadows, and pastures and much resembles in this respect the other mulleins, to which it is nearly related. A description of the plant together with photogravures are given, and it is stated that it begins to flower early in June when not more than 2 or 3 ft. high, at which time it is often unbranched. It continues to produce flowers and put out lateral branches and, if growing on good soil, attains a height of 8 or 10 ft. It is very prolific in the production of seed and on this account might become a serious pest.

Vegetative propagation of perennial weeds, A. S. HITCHCOCK and G. L. CLOTHIER (*Kansas Sta. Bul.* 76, pp. 23, pls. 12).—This bulletin, which is the fifth report on Kansas weeds, discusses the methods of vegetative propagation of perennial weeds. The weeds are divided according to the methods of their propagation into 3 classes. (1) those reproducing by creeping roots: Sumac (*Rhus glabra*), perennial ragweed (*Ambrosia psilostachya*), pasture thistle, Indian hemp, milkweed (*Asclepias cornuti*), climbing milkweed (*Enslenia albida*), bindweed

(*Convolvulus arvensis*), and sheep sorrel; (2) those from creeping stems: Poison ivy (*Rhus toxicodendron*), wild rose (*Rosa arkansana*), elder, golden-rods (*Solidago serotina* and *S. canadensis*), sunflowers (*Helianthus grosse-serratus* and *H. maximiliani*), wild artichoke (*H. tuberosus*), white morning-glory (*Convolvulus sepium*), smartweed (*Polygonum mihlenbergii*), nettle (*Urtica gracilis*), and nut grass (*Cyperus esculentus*); and (3) those which form crowns: Yellowwood sorrel (*Oxalis corniculata*), redroot (*Ceanothus oratus*), wild senna (*Cassia murilandica*), ironweed (*Vernonia baldwinii*), golden-rod (*Solidago rigida*), ox-eye daisy, dandelion, white vervain (*Verbena urticifolia*), blue vervain (*V. stricta*), catnip, motherwort, plantain (*Plantago rugelii*), rib grass, wild four-o'clock (*Orybaphus nycetagineus*), pokeweed, patience dock, pale dock (*Rumex altissimus*), curled dock, *Paspalum setaceum*, drop-seed grass (*Sporobolus cryptandrus*), and *Eragrostis pectinacea spectabilis*.

In addition, some modification of these methods of propagation is shown in the case of the horse nettle, ground cherry, wild artichoke, nut grass, dandelion, and rib grass. Methods for the destruction of perennial weeds are discussed at some length, based on the necessity of the development by the plant of some green leaves for the production of underground parts. The authors investigated the ability of root cuttings to produce adventitious roots in the case of ground cherries, milkweeds, pasture thistles, bindweeds, climbing milkweeds, dandelion, rib grass, and Jerusalem artichokes.

The underground parts of the various weeds previously mentioned are figured and described in considerable detail.

Notes gleaned by an experience in managing a weed garden, W. J. BEAL (*Proc. Soc. Prom. Agr. Sci., 1897, pp. 35-52*).—The author gives a report of observations made on a weed garden which has been in existence for about 10 years at the Michigan Agricultural College. The soil of the different plats has been given no cultivation and has become very compact. As would be expected whenever plants were at all crowded, those along the margin of the plats were much more vigorous than those in the middle. The perennial and biennial plants have remained in their respective plats, while the annuals have usually seeded themselves and have also found their way to adjacent plats. The growth of quite a number of species is described in considerable detail. Many of the species have decreased in vigor.

A list is given of 127 species of weeds which may be expected in central Michigan, the arrangement being alphabetical under the scientific names. An outline or syllabus is also given for a short course in the study of weeds and a bibliography of over 100 references to weeds and weed eradication.

On the destruction of cuscuta, E. NOFFRAY (*Agr. Rationnelle, 1898, No. 12*).

***Ceanthe crocata:* A study of its botany and its pathogenic effect on men and certain animals,** C. DEMOOR (*Ceanthe crocata. Étude botanique et étude des effets pathogéniques observés chez l'homme sain et certains animaux. Brussels: H. Lamertin, 1898, No. 83*).

Poisonous plants growing in meadows and pastures. E. NOTTRAY (*Agr. Rationnelle, 1898, No. 15*).

Exchange seed list. W. A. SETCHELL and J. B. DAVY (*California Sta., March, 1898, pp. 8*).—A list is given of duplicate seeds of the botanic garden which are offered for exchange only for seeds from other experiment stations and botanic gardens in the United States and abroad. In all, 220 species and varieties are listed.

Seed travelers. C. M. WEDD (*Boston: Ginn & Co., 1898, pp. 58, ill.*).—Treats of the methods of dispersal of various common seeds.

DISEASES OF PLANTS.

Diseases of plants. H. L. BOLLEY (*North Dakota Sta. Rpt. 1897, pp. 43-50*).—Aside from work on potato scab and rusts of cereal grains, the author has been collecting information relative to other diseases of plants. Some of the observations have not yet been published.

A brief report is given of a disease designated as blighting of wheat. Usually the heads have the appearance of sun scald or injuries resulting from excessive drought. During the past season the disease was especially destructive. At harvest a large portion of the heads were found with the upper half unfilled. Microscopic study of these blighted heads showed that the glumes and blighted grains were thoroughly infested with a fungus growth. Specimens have been examined by the author and others, and as yet there is no agreement as to the exact nature of the fungus. The author, however, is induced to believe that the fungus is a species of *Alternaria*. Further investigations are promised.

The author continued his investigation of the smuts of cereals, experimenting with formalin, "Ceres Pulver," and a tobacco extract known in the trade as "Roseleaf." The effect of these fungicides on the prevention of smuts of wheat, oats, and millet is shown in tables, and a comparison made with hot water and corrosive sublimate treatments. The treatment of wheat with "Roseleaf" seemed to increase the smut rather than diminish it. Formalin and corrosive sublimate gave the best results. In the treatment of oats the "Ceres Pulver" and formalin seemed to be equally efficient in preventing smut. The formalin solution was very efficient in preventing smut of millet. An experiment for the prevention of barley smut was attempted, but on account of the very small percentage of disease on the untreated plot, no conclusions can be drawn from the trial.

The comparative resistance of different varieties of oats to rust was also investigated, and further results are to be forthcoming.

The effect of different dates of seeding or possible variation in soil conditions upon the development of smuts in grain was investigated with wheat, oats, barley, and millet. This work was in continuation of that begun in 1896, and for the present the author thinks it is desirable to withhold the publication of results.

Prevalent diseases of cucumbers, melons, and tomatoes. A. D. SELBY (*Ohio Sta. Bul. 89, pp. 99-122, pls. 3, map 1*).—The author calls

attention to the serious decrease in yield of cucumbers for the season of 1897. The principal cause of this diminished yield is attributed to attacks of the downy mildew (*Plasmopara cubensis*) and the anthracnose (*Colletotrichum lagenarium*). Of these the downy mildew was the more destructive. The history and distribution of both these diseases is given. They are reported as having been observed in 10 States.

An experiment was conducted under the author's direction for the prevention of the downy mildew by 2 applications of Bordeaux mixture. Comparing the yields of sprayed and unsprayed rows, it was found that 25 sprayed rows yielded 51 bu. of cucumbers, while an equal number of unsprayed rows gave 38.4 bu. The cost of spraying seems unnecessarily high and could probably have been considerably reduced. Suggestions are given for the planting of cucumbers, allowing for roadways, so that power sprayers may be used.

The leaf blight of melons, due to *Alternaria* sp., which was described and figured in Bulletin 73 of the station (E. S. R., 8, p. 991), has again proved quite destructive during the season of 1897, and has extended its attacks to watermelon leaves. The muskmelon leaves, however, showed the earliest symptoms, dying off rapidly, with the characteristic spotting.

Notes are given on the tomato leaf blight fungus (*Septoria lycopersici*), which seems to have become well established throughout most of the State. It may be successfully prevented by the thorough use of Bordeaux mixture.

An experiment was conducted in which seeds were treated with copper sulphate solution and with hot water, to ascertain the effect of such treatment on the prevention of the tomato anthracnose. Soaking the seeds 1 and 2 hours in 10 per cent solution of copper sulphate or immersion for 5 minutes in water heated to 133° did no injury to the germination. The absence of all traces of diseases in these trials prevented any conclusions relative to the treatment of the disease.

Plant diseases in Java. M. RACIBORSKI (*Ztschr. Pflanzenkrank.*, 8 (1898), No. 2, pp. 66, 67).—The author reports the existence in Java of 2 undescribed diseases of the cowpea and the peanut. The fungi attack the leaves of their respective hosts and have both proved very destructive.

The disease of the cowpea is caused by *Cercospora vigna*. On the upper surface of the leaves it produces rounded or somewhat irregular spots 0.5 to 2 cm. in diameter. These spots often coalesce and the tissue becomes dead. On the under side of the leaves the spots are brownish gray, and after the formation of the spores they become dark rusty gray. The spots are not bordered. The mycelium is found about the fibro-vascular bundles and in the spongy parenchyma, but it does not send haustoria into the cells. The conidiophores are borne upon the under side of the leaves. The conidia are 3.5 to 5 μ in diameter and are very slender. The small ones measure 20 μ in

length and are 1-celled, while the most are 30 to 50 μ and 2 or 3 celled, while occasionally specimens are found 100 μ in length and have 8 to 10 cells. The conidia are able to produce spots on sound leaves in from 4 to 5 days; when severely attacked the leaves quickly dry up and fall from the plant.

The disease of the peanut is said to be due to an undescribed fungus (*Septoglaucum arachidis*) and whole fields are said to have been destroyed by it. It produces round, sharply bordered black spots with lighter centers and a clear yellow limiting border. The spots are usually 4 to 5 mm. in diameter, but vary from 3 to 10 mm. While usually found on the lamina and midrib of the leaf, the petioles and stems are also attacked. Infected leaves quickly fall, leaving the bare stems and a few young leaves. The mycelium of this fungus occurs in the parenchyma and sends numerous haustoria into the cells. The conidiophores are small and they bear numerous elliptical conidia, usually single-celled, but sometimes appearing as though 3 to 5 celled. They are 20 to 34 μ in length and 9 μ in diameter. By placing fresh conidia on leaves the characteristic spots are said to have been produced within four days.

A dangerous disease of the white pine (*Gard. Chron.*, 3. ser., 23 (1898), No. 588, p. 202).—The author calls attention to the serious disease of *Pinus strobus* due to *Peridermium strobil*. The disease is widely distributed in Germany, Denmark, and elsewhere, and is quite common in the nursery. The symptoms of the disease consist of a swelling on twigs or branches, frequently under a branch whorl. Soon the distinctive blister-like outgrowths appear, bearing the yellowish spores. In a short time the twigs dry up, the needles fall, and no new growth follows.

The alternate generation of this fungus occurs on the black currant, gooseberry, and other species of *Ribes*. This form is known as *Cronartium ribicola*, and it appears on the leaves in June as a yellow, rusty coating, followed by a number of brown hair-like outgrowths. On the currants, etc., while destructive, it has not been reported as epidemic. *Pinus strobus* in America is said not to be attacked by this fungus.

Experiments for the control of potato scab, H. GARMAN (*Kentucky Sta. Bul.* 72, pp. 9-23).—In 1896 the author conducted a series of experiments with corrosive sublimate and flowers of sulphur for the prevention of potato scab. The first series was conducted in the greenhouse. A scabby potato was planted in each of 6 10 in. flower pots, the soil in all having been previously baked for several hours. The results obtained by this somewhat limited experiment indicated that sulphur did not exercise any decided effect in checking the scab, while corrosive sublimate proved very efficient.

Later in the same season 10 tenth-acre plats which had been previously used in potato-scab experiments (the ground being infested with a potato-scab fungus) were planted with Early Rose potatoes, the object

of the experiment being to test the relative values of corrosive sublimate and flowers of sulphur. Half of each plat was retained as a check, and the seed planted on the other portions of the first 5 plats was treated for 1 hour with a solution of $4\frac{1}{2}$ oz. of corrosive sublimate to 30 gal. of water. Three of the plats receiving sulphur were given $7\frac{1}{2}$ lbs. and the other 2 received 9 lbs. of sulphur, the sulphur being dusted in the furrows before the seed was dropped. The conclusion drawn from the experiment, the results of which are tabulated, show that corrosive sublimate was quite efficient in checking potato scab, while the sulphur treatment did not possess any special value.

In 1897 the use of corrosive sublimate was further investigated by pot experiments with favorable results. In conclusion the author states that soaking potatoes for an hour in a solution of $4\frac{1}{2}$ oz. of corrosive sublimate in 30 gal. of water is an effective treatment. If stronger solutions are used the period of soaking must be diminished.

The fungicidal action of acetate of copper compared with that of the Bordeaux mixture, A. and F. RAVIZZA (*Bol. Not. Agr.*, 20 (1898), No. 5, pp. 206-211).—The authors conducted a series of experiments in which the fungicidal effect of acetate of copper and Bordeaux mixture as preventives of grape *Peronospora* were compared. The form of acetate of copper used was that known as Stecher's mixture, consisting of 51.3 per cent acetate of copper and 44.3 per cent sulphate of lime. Experiments were made in 3 different localities with these substances, the weather during the summer being hot and rainy and especially favorable for the development of the grape mildew. In the vineyard where the first series of experiments was conducted the soil was cultivated between the rows, wheat and vetches being alternately grown, and liberal applications of cow manure and mineral phosphates were given. The Stecher mixture was guaranteed to contain 350 gm. of basic acetate of copper per kilo of powder. Vines were sprayed May 16, June 13-15, 23-24. In the first application 300 vines were sprayed with a package of the Stecher powder dissolved in 50 liters of water; in the second and third treatments increased strengths of solution were used. In addition to spraying with Bordeaux mixture the vines after being sprayed were powdered with a 3 per cent sulphate of copper powder. The foliage of those vines which received the acetate of copper was noted before the end of the season to be of a darker green color than the leaves of the other vines. The *Peronospora* appeared during the first days of July upon the vines which received Bordeaux mixture and upon those receiving the Stecher powder about August 1. At that period, the weather being very rainy, the invasion of the fungus was very rapid, especially on those vines which had been treated with the acetate of copper powder. From these experiments the conclusion is drawn that while the acetate of copper was somewhat more efficient than Bordeaux mixture, as it washes off the leaves much more readily, more numerous applications will be required. It is also rec-

ommended that each treatment be followed with the application of powdered sulphate of copper.

A second series of experiments was conducted in a vineyard which was situated on a hillside with a southern exposure, the soil of which was clay. In this experiment different strengths of the 2 fungicides were compared. Three of the sprayings were followed with applications of sulphur. Bordeaux mixture used in full strength and acetate of copper in full strength or in half strength saved the vines from the attacks of the fungus. The half-strength Bordeaux mixture was less efficient, some of the vines being slightly injured. Sugar determinations of the grapes grown on vines receiving the different treatments showed practically no differences.

Another experiment made near by and conducted on a somewhat similar plan proved an almost total failure. In this case the vineyard was in a low-lying place; the soil was wet. Peronospora developed rapidly on the plants and the treatment was evidently begun too late in the season.

The authors conclude from their experiments that the acetate of copper is an active preventive agent against Peronospora, being about equal to Bordeaux mixture and in some respects better, as somewhat less is required than of Bordeaux mixture. The authors think, however, that more than 3 applications are necessary, that number being recommended by the manufacturers of the Stecher powder. From an economic consideration of the subject, they believe acetate of copper is not adapted to general use, as the cost is considerably greater than an equal amount of Bordeaux mixture.

Handbook for the preparation and use of chemical agents for the prevention of plant diseases, M. HOLLRUNG (*Handbuch der Chemischen Mittel gegen Pflanzenkrankheiten. Herstellung und Anwendung im Grossen*. Berlin: Paul Parey, 1898, pp. IV + 178).—This handbook, although from its title it would appear to be one dealing only with the preparation and use of fungicides, includes insecticides as well. The work is divided into 3 parts, the titles being animal, vegetable, and mineral substances, the latter being arranged according to inorganic and organic substances.

The literature of Europe and America has been well reviewed, and the information is fully up to date. More than 125 substances which are considered as having fungicidal or insecticidal value are discussed and numerous formulas given for their preparation. In many cases the specific value of the chemical agents for the prevention of certain insects or diseases is stated. The author has made a valuable contribution to the literature of the subject.

ENTOMOLOGY.

The weight of bees and the loads they carry, C. P. GILLETTE (*Proc. Soc. Prom. Agr. Sci.*, 1897, pp. 60-63).—A large number of weighings were made, which resulted in showing that outgoing pure Italian workers average 1.285 gm. or 5,578 bees to the pound; incoming honey-laden workers, 1.982 gm. or 3,532 to the pound; incoming pollen-laden workers, 1.349 gm. or 5,594 to the pound; incoming pollen bearers, 1.285 gm. or 5,447 to the pound, and drones, 3.173 gm. or 2,206 to the pound.

The weights were taken of honey stomachs from incoming workers, of honey loads and pollen loads, with the following average results: Honey stomachs, 0.879 gm. or 7,964 to the pound; honey loads, 0.638 gm. or 10,965 to the pound; and pollen loads, 0.173 gm. or 40,580 to the pound. The object of weighing was to determine the truth of the statement often made by bee keepers that pollen bearers also bear honey. In no case was it found that such was the case. What little honey is found in the stomach or used in sticking pollen to the legs seems to be a store carried with the bee from the hive.

Pterophoridæ of North America, C. H. FERNALD (*Massachusetts Agr. Col. Rpt.* 1897, pp. 85-162, pls. 9).—The subject is treated monographically. After briefly noting the wide geographical distribution, that none of this family have thus far been recognized among fossils, and the few natural enemies (*Pimpla pterophori*, *Limneria pterophora*, and *Ichneumon humilis*), the author proceeds with a historical résumé of the literature, and an account of the structure and habits, systematic position, and characteristics of the family, finally treating the various species in detail. Synoptic tables are given with each genus.

The Pterophoridae fly usually on warm, quiet evenings, when they are occasionally attracted to light, though rarely to sugar. In the daytime they are easily flushed from shrubbery and fly but a short distance. When at rest the wings are held horizontally at right angles to the body with the feathers of the hind wings folded over each other and drawn under the wings. Whether any of the North American species have more than one generation is not known, although in Europe *Acanthodactyla* and *Monodactyla* are said to have two generations, and it is very probable that the same may be true in some cases at least in this country. Of the species noted, the food plants of the following are known: those of the others have not yet been discovered: *Trichoptilus lobidactylus* on *Solidago canadensis*; *Platyptilia cosmiodactyla* on *Stachys*, *Aquilegia*, *Geranium*, and *Orthocarpus*; *P. acanthodactyla* on *Stachys*, *Mentha*, *Ononis*, *Calamintha*, *Pelargonium*, and *Euphrasia*; *P. carduidactyla* on *Cirsium lanceolatum*; *P. orthocarpi* on *Orthocarpus*; *P. tessera-dactyla* on *Gnaphalium dioicum* and *G. arenarium*; *Alucita montana* on *Solidago*; *Pterophorus homodactylus* on *Solidago* and *Eupatorium purpureum*; *P. helianthi* on *Helianthus*; *P. palcaceus* on *Vernonia noveboracensis*; *P. kellicottii* on *Solidago*; *P. monodactylus* on *Conoclelus sepium*, *C. arrensii*, *Chenopodium album*, and *Atriplex patula*; *P. eupatorii* on *Eupatorium purpureum*; *P. grisescens* on *Artemisia*; *P. inquinatus* on *Ambrosia artemisiifolia*, and *Stenoptilia pterodactyla* on *Veronica chamædrys*.

Some strawberry insects, A. L. QUAINANCE (*Florida Sta. Bul.* 42, pp. 551-600, figs. 23).—This bulletin treats popularly of the more injurious insects of the strawberry occurring in Florida. Life histories are given more or less in detail and remedies noted. Thrips have been unusually abundant, damaging the strawberry crop throughout the State. Although it affects other field plants during the entire spring and summer, the strawberry plant seems to furnish its favorite food. It attacks different flowers differently. In orange blossoms the petals and stamens are chosen; in strawberries the pistils, resulting in the latter case in preventing or retarding the fertilization of the ovules. On some blossoms the author notes the presence of as many as 65 insects.

Bodies were pressed from females which were regarded as eggs. They measured 0.6μ by 0.1μ and were found in numbers of from 2 to 5, usually 3, per insect.

Several remedial mixtures were tried, including a sulphur spray, flowers of sulphur, pyrethrum, pyrethrum and water, pyrethrum decoction, tobacco dust, tobacco decoction, kerosene emulsion, whale oil soap, etc., but none were found to be as efficient as the compound known as "rose-leaf" insecticide. This was efficient both in killing the insects and in not affecting the taste of the berries, which some of the other insecticides invariably did when employed late. Aside from not affecting the berries, this insecticide is thought superior, from the fact that

a slight stickiness that it possesses prevents the insects from escaping and in the fact that its action is rapid.

The strawberry pamera (*Pamera vineta*) seems to be reported for the first time as of economic importance. In Florida it has been recognized for several years past as an enemy to strawberries. It was observed in 1892 by P. H. Rolfs feeding on the young berries: the "buttoning" of young fruit is attributed to it. In the laboratory insects were observed to feed mainly on the ovaries of the plants.

"Walking around over the berry, the beak was thrust first down into one ovary and then another, frequently 15 or 18 ovaries being pierced during the course of half an hour. As is well known, the ovary is, physiologically, an essential part of the fruit of the strawberry, and if a considerable number of ovaries are destroyed the development of the receptacle—the juicy part of the ripe strawberry—is checked. This insect seems to destroy the vitality of the ovaries which it attacks. In case the attack has been severe, i. e., many of the ovaries of the fruit having been pierced, the berry rarely develops to anything of value. Further growth is greatly checked and the receptacle eventually becomes more or less woody, producing a button. Very young fruit seems to suffer more severely yet. In such fruit the receptacle is also attacked, and it usually results in the blackening and eventual drying up of the berry. This effect was observed repeatedly in the laboratory. Blossoms are sometimes attacked with the same results. One insect may so pierce a very young fruit or blossom that it will die. After a berry has become a third grown it is probably safe from destruction by this insect."

The egg, the 5-nymph, and the adult stage are described, quoting from Say. Some discrepancies were observed by the author between specimens and Say's description.

"The length will average about $\frac{1}{2}$ in., nearly twice that given by Say. However, there is much variation in length; the bodies of some males measure but $\frac{5}{8}$ of an inch, while some of the longest females measure $\frac{7}{8}$ of an inch. The membrane of hemelytra is much clouded with dusky above; below it is milk white. The feet are dusky. The claw and distal segment of each tarsus are blackish, the clouding extending upon the tibia; not whitish. The basal joint of the antennæ is uniformly yellowish, there being no trace of black on distal portion.

"The antennæ of an adult are very similar to that of the nymph, the first joint being short, about two and one-half times as long as thick; second, third, and fourth joints are of about same length; second and third are cylindrical in shape; fourth joint is spindle shaped. First, second, and third joints are uniformly yellow; fourth joint rufous. Tarsi composed of 3 segments."

Laboratory observations resulted in showing that the duration of the life cycle of the insect is as follows: Egg stage, 8 days; first nymph stage, 5 days; second, 3 days; third, 3 days; fourth, 3 days; fifth, 5 days; total to adult stage, 27 days. Adults were kept in the breeding cage 20 days, or until they escaped.

In the field it was observed that young are less affected than old fields and that the custom of mulching offers the insects admirable places for breeding. The insect is thought to be indigenous to the State and its taste for strawberries acquired. Spraying with rose-leaf insecticide is recommended.

The tarnished plant bug (*Lygus lincolaris*) is regarded as injurious,

although it can not be regarded at present as seriously menacing strawberry growing in Florida. As remedies kerosene emulsions and pyrethrum are noted.

The leaf-footed plant bug (*Leptoglossus phyllopus*) not infrequently attacks the strawberry, sucking the fruit and tender shoots, sometimes doing considerable damage, though its usual food plant in Florida appears to be the thistle *Carduus spinosissimus*. Nymphs were observed on the Irish potato. Hand picking is recommended.

The negro bug (*Corimelana pulicaria*), although more abundant in Florida on blackberries, also frequently does considerable damage to strawberries, the injury being mostly due to the odor it imparts to the berries. Hot water (155° F.) is noted as a remedy.

Cutworms, principally *Agrotis ypsilon*, are frequently abundant. One grower gave the information that he had dug out 600 daily for a week; another that he found 40 near a single plant.

The remaining insects noted are white grubs (*Lechnosterna* spp.), strawberry flea-beetle (*Haltica ignita*), grasshoppers, crickets, the strawberry weevil, the strawberry crown borer (*Tyloderma fragariae*), and strawberry-leaf roller (*Phloxopteris comptana*). The last 2 insects, however, have not yet been found in Florida. The life history of *H. ignita* is thought to be somewhat similar to that of the grapevine flea-beetle. No record is known of the larvæ feeding on the leaves of the plant, and it is regarded as possible that they attack the roots.

Two spraying machines are figured.

Some injurious insects of the orchard, E. E. FAVILLE and P. J. PARROTT (*Kansas Sta. Bul.* 77, pp. 25-62, figs. 32).—This is a popular discussion of the following insects, including descriptions, life histories, habits, injuries, remedies, etc.: Cankerworm (*Paleacrita vernata*), codling moth (*Carpocapsa pomonella*), tent caterpillar (*Clisiocampa americana*), plum cureulio (*Conotrachelus nenuphar*), plum gonger (*Coccotorus scutellaris*), peach-tree borer (*Sannina exitiosa*), flat-headed borer (*Chrysobothris femorata*), round-headed borer (*Saperda candida*), San José scale (*Aspidiotus perniciosus*), and elm-twig girdler (*Oncideres cingulatus*).

The spring cankerworm has steadily spread into the fruit regions of the State until now it is regarded as one of the leading orchard pests. The insect attacks forest and shade trees as well as fruit trees. The remedies suggested are to prevent the wingless female from ascending the trunks of trees, and to spray the trees with poisons. The first may be done by the use of sticky mixtures, such as printers' ink, pine tar, resin and castor oil, dendrolene, raupenleim, etc., applied as a band to the trunk of the trees or by the use of collars of tin, paper, etc., fastened about the trees. The author gives the following summary of results of spraying: "Trees sprayed with Paris green were not scalded; loss from the work of larvæ from 1 per cent to 5 per cent. Trees sprayed with soluble arsenic solution showed leaves scalded 5 per cent, larvæ completely destroyed. Trees sprayed with insoluble arsenic solution showed leaves free of scald, 1 per cent of leaves destroyed by larvæ."

The plum curculio is the worst enemy of the plum, having become distributed throughout the State. The remedies commonly used—spraying and jarring—are recommended.

The peach-tree borer is regarded as the most widely distributed insect enemy of the peach in the State. The author believes that the danger to the tree from digging out the larvæ makes that remedy impracticable. The best method is thought to be any means of preventing the adult insect from depositing its eggs. Hilling up the soil around the trees, or placing tarred paper or even wire netting about the trunks to the height of 2 ft., is suggested. Obnoxious washes which will keep the moths away are noted.

As remedies against the flat-headed borer, it is suggested to keep the trees in a healthy condition, to stimulate vigorous growth, which will increase the flow of sap and usually cause the death of the larvæ by drowning, to dig out larvæ with a knife, and to use alkaline washes on the trunks of trees.

A spray calendar, giving directions for the treatment of the most important insect enemies and diseases of a number of plants, the preparation of insecticides, fungicides, etc., is included with the bulletin.

The gypsy moth in America, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Bul. 11, n. ser., pp. 39, figs. 5, maps 3*).—This bulletin gives the results of an investigation of the gypsy moth made in accordance with a clause in the section of the agricultural appropriation bill making appropriations for the year 1897. A general review of the history of the moth and its introduction into this country, its occurrence in Europe, and the methods of extermination adopted in Massachusetts are given. The only seemingly sound objection to the work, i. e., that large numbers of insectivorous birds and their nests must be destroyed, is answered by the statement that the work of the men is timed where possible so as not to interfere with the nesting of useful birds, and that the nests of the English sparrow are always destroyed where met with.

The value of the burlap method of collecting is brought out, and the fact noted that in 1897 the larvæ seemed to have changed their habits somewhat. Instead of hiding under the burlap in large numbers during the day, as formerly, they were found in the trees. This change seemed to coincide with the general cloudy and damp character of the weather, and was overcome by the greater use of the spraying method and also by jarring the worms from the trees and killing them beneath the burlaps.

The inefficiency of any single method and the ability of the worms to resist poisons is brought out.

The San José scale in 1896 and 1897, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Bul. 12, n. ser., pp. 31, fig. 1*).—This bulletin is supplementary to Bulletin 3, n. ser., of the Division (*E. S. R.*, 8, p. 500), and brings together information gained by the economic entomolo-

gists of the country during the past 2 years. A map is given showing the known distribution of the San José scale, accompanied by notes on its present condition in the following States: Alabama, Arkansas, Arizona, California, Connecticut, Delaware, District of Columbia, Florida, Georgia, Idaho, Illinois, Indiana, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New Mexico, New York, North Carolina, Ohio, Oregon, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, Washington, West Virginia, and Canada.

Seventeen new food plants have been listed. They are as follows:

“*Orchard fruits*.—Pear, peach, apple, plum, cherry, Rocky Mountain dwarf cherry, persimmon, quince, flowering quince. *Small fruits*.—Strawberry. *Bush fruits*.—Raspberry, gooseberry, grape, currant, flowering currant, black currant. *Nut plants*.—Almond, chestnut, pecan, black walnut, English walnut, Japan walnut. *Ornamental plants, forest, and shade trees*.—Rose, hawthorn, spirea, cotoneaster, euonymus, English huckleberry, linden, acacia, elm, osage orange, alder, sumac, weeping willow, English willow, golden willow, laurel-leaved willow, milkweed, catalpa speciosa, Lombardy poplar, Carolina poplar, golden-leaved poplar, silver maple, cut-leaved birch, mountain ash, Japanese quince, actinidia, Citrus trifoliata, red dogwood, snowball, Juneberry, loquat, laurel, and akebia.”

The difference between the San José scale and 2 closely allied species, the Putnam scale (*Aspidiotus ancyclus*) and the Forbes scale (*A. forbesi*) are pointed out. The relation of climate to the spread of the insect is briefly discussed.

In regard to natural enemies of the scale, the author says that in no case since the publication of the former bulletin have any insect enemies been reported as doing any good. Specimens of Australian ladybirds were distributed in New Jersey and at Washington, but no results have been obtained from them. The identification and study of a parasitic fungus (*Sphaerostilbe coccophila*) by the Florida Station (E. S. R., 9, p. 1068) and work with it in New Jersey and elsewhere is noted.

In regard to remedies the work of the Virginia Station with the gas treatment and with pure kerosene (E. S. R., 9, pp. 672, 1067) is reviewed, as is also the work with kerosene at the Georgia, Ohio, and New Jersey Stations (E. S. R., 9, p. 1066; 10, p. 161).

In experiments of the Division of Entomology, peach, pear, cherry, and apple trees sprayed with pure kerosene while their buds were dormant were uninjured. On some of the trees 99 per cent of the scales were killed by the kerosene. Cases are noted, however, in which orchards sprayed with kerosene were very seriously injured. Therefore the author recommends the use of kerosene on a small scale at first to determine whether it can be advantageously used in different localities.

Recent legislation in regard to the San José scale is briefly noted, and the German edict in relation to the importation of plants and fruits from America is given.

A bibliography is given including publications during 1896 and 1897 and omissions from the previous bibliography.

The chinch bug, H. GARMAN (*Kentucky Sta. Bul. 71, pp. 45-70, fig. 1, pls. 7*).—The bulletin discusses the distribution and injury of the chinch bug in Kentucky, its characteristics, habits, etc., and methods of treatment. The meadow lark and quail are noted as the two birds known to feed on the chinch bug. Toads are also said to be useful in destroying this insect. Chinch bug fungi are discussed at considerable length, and methods of growing and using fungi are given. Among other remedies the following are discussed: Barriers, deep plowing, early planting, fertilizers, planting timothy with wheat, and the use of fire, coal oil, steam, etc.

A bibliography of the more important articles on the chinch bug is given, with notes on the scope of each article.

The periodical cicada (*Cicada septendecim*), or so-called seventeen-year locust, in Ohio, F. M. WEBSTER (*Ohio Sta. Bul. 87, pp. 37-68, figs. 11, pl. 1*).—The structure, life history, habits, injuries, and natural enemies of the cicada are given. The summary of the bulletin is, in part, as follows:

“The principal injury done by the insect is by puncturing the twigs and limbs of trees and shrubs and the canes of raspberry and blackberry bushes.

“There are four well-marked and strong broods in Ohio during the 17-year period.

“The adults are destroyed by the English sparrow and to a small extent by other birds.

“Kerosene emulsion and pyrethrum mixed will destroy the newly emerged adults.

“Hogs root out and destroy the pupae, and domestic fowls destroy the adults.

“It is best not to prune trees, especially young orchards, the season preceding an occurrence of the Cicada, and it is also better to forego planting during the same period.”

List of original types of species in the superfamily Jassoidea, C. P. GILLETTE (*Colorado Sta. Bul. 43, pp. 30, 31*).—This is a list of the species of Jassoidea now in the collections of the College of Agriculture and Experiment Station. “The list is for the information of students in entomology and also for the purpose of correcting a statement in regard to ‘true type specimens’ made by C. F. Baker in an article entitled ‘Notes on the Genus *Deltoccephalus*’ and published in the current volume of *Psyche*, p. 114.”

A few new species of *Deltoccephalus* and *Athysanus* from Colorado, C. P. GILLETTE (*Colorado Sta. Bul. 43, pp. 23-29, figs. 4*).—The following new species are described: *Deltoccephalus parvulus*, *D. cookei*, *D. blandus*, *D. labiata*, *D. atropuncta*, and *Athysanus ornatus*.

Descriptions of new genera and species of the Geometrina of North America, G. D. HULST (*Canad. Ent., 30 (1898), No. 7, pp. 191-195*).—*Diastictis benigna*, *D. sericeata*, *Jabarella*, n. g., *J. danbyi*, *Spodoptera kunzei*, *Ethyctera lineata*, *Aleis mastosa*, *A. lallata*, *Selidosema configurata*, *S. lachrymosa*, *Cleora subaustralis*, and *C. pedicellata*.

Two new species of *Kermes* from Kansas, E. E. BOGUE (*Canad. Ent., 30 (1898), No. 7, p. 172*).—*Kermes pubescens*, on twigs and leaves of oak (*Quercus macrocarpa* and *Q. prinoides*); reported also on *Q. macrocarpa*. It occurs very thickly on young twigs and leaves. *Kermes concinnulus* on *Q. macrocarpa*, allied to *K. cockerelli*.

Concerning the ovular envelopes of some of the Chrysomelidæ, A. LECAILLON (*Arch. Anat. Micros., 2 (1898), No. 1, pp. 89-117, pl. 1*).

The development of the embryo of some Chrysomelidæ, A. LECAILLON (*Arch. Anat. Micros., 2 (1898), No. 1, pp. 118-176, pl. 1*).

Structure and classification of insects (*Bul. Soc. Cent. Hort. Seine-Inférieure*, 2. ser., 2 (1898), No. 2, pp. 155-178).

The San José scale, W. J. PANTON (*Ontario Agr. Col. and Expt. Farm Bul.* 106, pp. 3-7, fig. 1).—A popular article on the San José scale, its life history, injuries, distribution, etc. The various remedies in use are briefly considered.

The San José scale in Oklahoma, E. E. BOGUE (*Oklahoma Sta. Bul.* 31, pp. 8, figs. 3).—The San José scale is reported as having invaded the Territory, and this bulletin is a brief popular account of it and its life history. The source of introduction seems at present to be from Texas.

As remedies salt, sulphur, and lime solution were employed with success. It is thought that in Oklahoma it would be best for every man to be a law to himself rather than depend upon restrictive legislation.

The importation of the San José scale (*Aspidiotus perniciosus*) from Japan, F. M. WEBSTER (*Canad. Ent.*, 30 (1898), No. 7, pp. 169-172).—It is noted that in April, 1898, the author found *Aspidiotus perniciosus* and *Diplosis amygdali* on Japanese white flowering cherry trees which were received directly from Japan during the winter of 1896-97. The isolation of the trees, although they had been growing in this country for a year, is thought sufficient proof that the scales came from Japan. Another lot of trees which had never been removed from the storehouse in which they were placed when they came from Japan were examined and found infested with the pernicious scale. The author believes with T. D. A. Cockerell that the scale is a native of Japan, and explains the fact that it is not as injurious and numerous there by the probable existence and influence of natural enemies, which he suggests might be brought to this country.

The San José scale in Massachusetts, A. H. KIRKLAND (*Massachusetts Crop Rpt.*, June, 1898, pp. 24-38, figs. 3).—A popular summary of recent literature on and a discussion of this insect as found in Massachusetts. To a discussion of the usual questions, one on the nursery question is added. The natural laws of trade are thought more potent than those framed by legislatures. There is added beside very good advice to nurserymen and purchasers.

San José scale (*Pennsylvania Dept. Agr. Bul.* 34, pp. 45-49).—Notes are given on Rolfs' and Smith's work with the San José scale.

Erratum.—The statement on page 271 of the preceding number of the Record, to the effect that the appearance of the San José scale in Iowa was noted, is erroneous. The authors state instead that "no occurrences have as yet been detected."

The allied species in Europe of the San José scale, FRANK and KRÜGER (*Gartenflora*, 47 (1898), No. 15, pp. 393-400, figs. 6).

A contribution to the knowledge of the red spider (*Tetranychus telarius*), C. VON TUBEUF (*Forstl. Naturw. Ztschr.*, 7 (1898), No. 7, pp. 248-251, figs. 3).

Insects injurious to roses, E. LUCET (*Bul. Soc. Cent. Hort. Seine-Inférieure*, 2. ser., 2 (1898), No. 2, pp. 135-152, pl. 1).—This is one of a series of articles giving descriptions of insects injurious to roses, with remedies, etc.

Insect enemies of the grapevine, L. BRUNER (*Nebraska Hort. Soc. Rpt.* 1895, pp. 68-162, figs. 96).—A list is given of 148 species of insects known to attack the grape. Some 30 of the most injurious of these are described and figured with notes on their life histories. The methods found most successful in combating these insects are given.

Phylloxera of the vine: Treatment by means of carbon bisulphid, J. BRAHAMARY (*Des vignes phylloxérées: De leur traitement par le sulfure de carbone. Alger: Fontana & Co., 1898, pp. 12*).

Injurious insects of the forests of the Government of Kiev, S. TORSKI (*Selsk. Khoz. i Lyesov.*, 188 (1898), No. 2, pp. 413-428).

Remedies for the destruction of insect pests, fungi, etc. (*California Ed. Hort. Rpt.*, 1895-96, pp. 56-63).—Formulas and directions for the preparation of several insecticides and fungicides are given, with notes on other remedies.

Notes on some sawfly larvæ, especially the Xyelidæ, H. G. DYAR (*Canad. Ent., 30 (1898), No. 7, pp. 173-176*).

Classification of the horntails and sawflies or the suborder Phytophaga, W. H. ASHMEAD (*Canad. Ent., 30 (1898), No. 7, pp. 177-183*).—This, the second paper, takes up the series Xylophaga. In the family Oryssidæ 4 genera, Chalimus, Ophrynopus, Moesarya, and Oryssus are recognized; in the family Siricidæ, the subfamilies Siricinae and Tremecinae and the genera Sirex and Paururus of the first and Xeris, Teredon, and Tremex of the second subfamily. In the family Xiphydriidæ 2 subfamilies, Derecyotinae with the single genus Derecyota, and Xiphydriinae with 4 genera, Brachyxyphus, Philippi, Xiphydria, and Konowia; and in the remaining family, Cephidæ, the genera Cenocephus, Pachycephus, Syxista, Macrocephus, Calamenta, Astatus, Cephus, Trachelus, Monoplopus, and Ateuchopus.

A new species, *Cephus granicheri*, from Wisconsin, is described.

The described species of Xiphidium in the United States and Canada, S. H. SCUDDER (*Canad. Ent., 30 (1898), No. 7, pp. 183, 184*).—A key to 10 species of the genus.

Icerya purchasi, a new scale of orange, O. KLEIN (*Gartenflora, 47 (1898), No. 16, pp. 435-436, fig. 1*).

Insect pests and tree diseases (California Bd. Hort. Rpt. 1895-96, pp. 23-32, pls. 5, fig. 1).—Insects and tree diseases common in the Eastern States and in foreign countries and liable to be introduced into California are described and figured, with notes quoted from various entomological writers. A list of all vessels arriving in the State from July, 1891, to August, 1896, inclusive, is given, together with lists of plants contained on them and notes as to the disposition made of them at the quarantine offices.

Injurious insect pests found on trees and plants from foreign countries, A. CRAW (*California Bd. Hort. Rpt. 1895-96, pp. 33-55, pls. 6, figs. 6*).—Some 40 insects are described and figured.

A twig gall of pine caused by Phytoptus pini, C. VON TUBEUF (*Forstl. Naturw. Ztschr., 7 (1898), No. 7, pp. 252, 253, fig. 1*).

The fir-tree root louse (Pheumphigus poschingeri), C. VON TUBEUF (*Forstl. Naturw. Ztschr., 7 (1898), No. 7, p. 251*).

Contributions to a monograph of coniferous plant lice, I, N. CHOLODKOVSKY (*Horac Soc. Ent. Ross. [St. Petersburg], 31 (1898), pp. 78, figs. 36; abs. in Zool. Centbl., 5 (1898), No. 16, pp. 527-530*).—This paper treats of the species of Lachnus, of which 6 species frequent the pine, 7 are reported from the spruce, 3 from the fir, 3 from the larch, 2 from the juniper, and 1 from the cypress.

The life history of Lyda steliata and Lerythrocephala, K. SAJG (*Forstl. Naturw. Ztschr., 7 (1898), No. 7, pp. 237-247*).

Colorado Lepidoptera, C. P. GILLETTE (*Colorado Sta. Bul. 43, pp. 3-22, fig. 1*).—This is a list of Lepidoptera collected in Colorado, with brief notes on dates and localities of capture, names of collectors, food habits, etc.

The story of the lives of a butterfly and a moth, F. M. WEBSTER (*Ohio Sta. Bul. 86, pp. 25-33, figs. 6*).—The bulletin is intended for the young, especially school children, and gives something of the form and life history of a common moth and butterfly.

Insecticides: Their preparation and use, W. E. BRITTON (*Connecticut State Sta. Bul. 126, pp. 3-12, figs. 3*).—The bulletin gives a popular account of the following insecticides and directions for their preparation: *Internal poisons*.—Paris green, London purple, arsenate of lead, and hellebore. *Contact poisons*.—Whale-oil soap, kerosene, kerosene emulsion, kerosene and water, fir-tree oil, tobacco, and pyrethrum. *Poisonous and suffocating fumes*.—Tobacco fumes, hydrocyanic gas, and carbon bisulphid. A list of plants is given, together with a list of the insects most commonly attacking them and notes on the remedies to be employed in each case.

Spray calendar, L. C. CORBETT (*West Virginia Sta., folio*).—This gives tabulated directions for the treatment of a large number of insect pests and diseases, with formulas and directions for the preparation of several fungicides and insecticides.

Paris green, G. W. SHAW and J. F. FULTON (*Oregon Sta. Bul.* 49, pp. 3).—The bulletin discusses briefly the composition of Paris green, adulteration and its detection, etc. Analyses of 18 samples of Paris green are reported.

Reports of the quarantine officer and entomologist, A. CRAW (*California Bd. Hort. Rpt.* 1895-96, pp. 127-135).—A summary of the work of the quarantine officer and entomologist from April, 1895, to May, 1896.

Recent laws against injurious insects in North America together with laws relative to foul brood, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Bul.* 13, n. s., pp. 68).—This is a compilation of laws relating to injurious insects and foul brood in North America, together with some proposed National and State legislation.

FOODS—ANIMAL PRODUCTION.

On wheat and rye bread with special reference to the question of army bread, H. PODA, with preface by W. PRAUSNITZ (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 1898, No. 7, pp. 122-190, figs. 2).—Experiments are reported on the digestibility of white wheat bread and rye bread with 4 healthy men ranging from 19 to 26 years of age. The bread was consumed with butter, wine, and sugar. Special attention was given to the preparation of the bread. The best sort of flour was used, but, according to the author, as shown by microscopic examination wheat could not be as finely ground as rye. The coefficients of digestibility of the 2 sorts of bread in the different experiments are shown in the following table:

Comparison of the digestibility of white-wheat bread and rye bread.

Subject.	Food consumed per day.	Coefficients of digestibility.				
		Dry matter.	Organic matter.	Nitro-gen.	Ether extract.	Ash.
		<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Medical student V.	Rye bread 1,903 gm., butter 247.5 gm., wine 2,250 gm., sugar 45 gm.	94.47	94.92	65.29	94.47	68.21
Medical student S.	Rye bread 1,820 gm., butter 251.5 gm., wine 2,250 gm., sugar 45 gm.	94.37	94.75	63.82	93.94	70.05
Medical student V.	White bread 1,956 gm., butter 245 gm., wine 2,250 gm., sugar 45 gm.	96.47	96.82	83.15	96.40	71.72
Law student P.	Rye bread 1,285 gm., butter 240 gm., wine 1,500 gm., sugar 30 gm.	94.97	95.52	68.10	95.05	62.94
Mechanic G.	Rye bread 2,076 gm., butter 250 gm., wine 500 gm., sugar 45 gm.	95.78	96.24	74.67	95.25	67.50
Law student P.	White bread 1,275 gm., butter 213 gm., wine 1,500 gm., sugar 30 gm.	96.57	97.02	84.62	97.41	66.34
Mechanic G.	White bread 1,370 gm., butter 212 gm., wine 500 gm., sugar 30 gm.	96.26	96.76	83.21	96.04	69.33

The following conclusions were reached: When rye bread is eaten more feces are excreted and the percentage of nitrogenous material in the feces is larger than when wheat bread is eaten. In other words, rye bread is not as well digested as wheat bread. When thoroughness of digestion is an object the cheaper sorts of wheat flour should be substituted for rye flour. The bread supplied to some of the regiments of the German army is made of a mixture of rye and wheat flour, and this practice should be extended.

The article contains considerable controversial matter. The authors object to the deductions of Plagge and Lebbin (*E. S. R.*, 9, p. 872).

Report of a practical test of the use of the emergency ration by United States troops on active service, C. SMART (*Com. Gen. Sub-sist. U. S. Army Rpt. 1897, pp. 12-19*).—Two tests were made of the emergency ration of the United States Army with cavalry soldiers near Fort Sill, Oklahoma. In one test 16 officers and men, averaging 158 lbs. in weight, were given the emergency ration for 10 days. The ration consisted of 12 oz. bacon, 11.2 oz. hard bread, 5.4 oz. flour, 2.4 oz. beans, 1.2 oz. sugar, 16 oz. potatoes, and some coffee, salt, and pepper. A portion of the food was not eaten. The average quantity consumed per man per day was 10.2 oz. bacon, 11.2 oz. hard bread, 2.2 oz. flour, 0.8 oz. beans, 16 oz. potatoes, and 0.95 oz. sugar. This was calculated to furnish 3.32 oz. protein, 7.68 oz. fat, and 15 oz. carbohydrates with a fuel value of 4,145 calories. The average loss in weight per man was 1.35 lbs.

The special emergency ration was tested with 10 men. This consisted of 8 oz. hard bread, 5 oz. bacon, 2 oz. pea meal, with coffee, saccharin, salt, pepper, and tobacco.

During a 10 days' test the men marched on an average 21 miles a day, and lost 2,935 lbs. in weight. They remained in good health and spirits. All the ration was consumed. It was calculated that it furnished 2,128 oz. protein, 3,809 oz. fat, and 6,93 oz. carbohydrates and yielded 2,055 calories.

The chemical composition and nutritive value of some edible American fungi, L. B. MENDEL (*Amer. Jour. Physiol., 1 (1898), No. 11, pp. 225-238*).—To determine their nutritive value a number of edible fungi were analyzed and their digestibility determined by methods of artificial digestion.

The composition of the different fungi examined is shown in the following:

Composition of various edible fungi.

	In dry substance.							
	Water.	Total nitrogen.	Albuminoid nitrogen.	Non-albuminoid nitrogen.	Fat.	Soluble carbohydrates.	Crude fiber.	Ash.
Shaggy coprinus (<i>Coprinus comatus</i>)	<i>Per ct.</i> 92.19	<i>Per ct.</i> 5.79	1.92	3.87	3.3	18.0 ¹	7.3	12.5

Fairy ring mushroom (<i>Marasmius oreades</i>)	74.96	5.97						7.23

¹ Calculated as dextrose.

² Young small specimens.

³ Full grown specimens.

The variation in composition of different mushrooms is discussed. Among the bases found in the ash were potassium, sodium, and sometimes calcium. Iron was always present. Sulphuric and phosphoric acids predominated and chlorine was occasionally found.

The dry material was first digested with pepsin and hydrochloric acid and afterwards with a solution of dog pancreas, a little chloroform being added to prevent fermentation and also thermolized extract of dry pancreas powder. The undigested residue was eventually removed and dried and the nitrogen in it determined.

The total digestible nitrogen was determined by subtracting the nitrogen in the undigested (insoluble) residue from the total nitrogen of the original substance.

The nitrogen in the undigested residue was also subtracted from the total albuminoid nitrogen, the difference multiplied by 6.25, in the author's opinion, representing the true digestible protein in the mushrooms.

The results of the digestion experiments are summarized as follows:

Coefficients of digestibility of various species of edible fungi.

	Total undigestible material.	Nitrogen in undigestible material.	Proteid nitrogen.			Albuminoid nitrogen.		True digestible protein.
			In original substance.	Undigestible.	Digestible.	In original substance.	Digestible.	
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Shaggy mushroom.....	26.21	4.21	5.79	1.10	4.69	1.92	.82	5.12
Inky coprinus.....	28.16	2.79	4.68	.78	3.90			
Common morel.....	49.42	4.16	4.66	2.05	2.61	3.49	1.44	9.00
Oyster mushroom.....	59.43	1.39	2.40	.82	1.58	1.13	.31	1.94
Sulphury polyporus.....	55.00	1.05	3.29	.58	2.71	2.23	1.65	10.31
<i>Citocybe multiceps</i>	37.57	1.96	5.36	.73	4.63	1.98	1.25	7.81
<i>Hypoloma candolleianum</i>	31.98	3.63	4.28	1.16	3.12	2.49	1.33	8.31

The fact is pointed out that considering the high water content and the comparatively small amount of digestible protein which they contain, mushrooms do not have a high food value. In this respect they resemble ordinary vegetables and the term "vegetable beefsteak" which is often applied to them is very erroneous.

"The carbohydrate content of the fungi is relatively high; but until more is known regarding the nature and digestibility of the carbohydrate constituents of various vegetable foods, it will be useless to draw comparisons. As dietetic accessories the edible fungi may play an important part; but investigation has demonstrated that they can not be ranked with the essential foods."

Chemical composition and digestibility of edible fungi, M. STAHL-SCHRÖDER (*Selsk. Khoz. i Lysesov., 181 (1897), Feb., pp. 137-446*).—This investigation includes analyses of several varieties of edible fungi, detailed analyses of the ash constituents, and digestion experiments with rabbits and by artificial digestion.

The composition of the edible fungi is shown in the following table:

Composition of edible fungi.

	Water-free substance					
	Water.	Protein.	Albumin	Fat.	Carbohy- drates.	Cellulose.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
<i>Boletus edulis</i>	84.19	47.36	27.90	3.08	34.81	5.58
<i>Agaricus deliciosus</i>	89.98	31.66	21.41	6.16	51.04	3.60
<i>Cantharellus cibarius</i>	90.93	20.84	13.71	7.35	68.80	3.79

The ash constituents of the 3 varieties of edible fungi were as follows:

Composition of ash of water-free substance of edible fungi.

	Crude ash.		Carbon dioxide.		Pure ash.		Sulphuric acid.		Silica.		Phosphoric acid.		Potassium and sodium oxids.		Iron, manganese and aluminum oxids.		Calcium oxid.		Magnesium oxid.	
	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.	P. et.
<i>Boletus edulis</i>	9.17	0.15	0.21	8.81	1.24	0.05	2.18	4.39	0.19	0.31	0.21									
<i>Agaricus deliciosus</i>	7.54	.05	.84	6.65	.18	.06	1.66	3.89	.08	.09	.14									
<i>Cantharellus cibarius</i>	9.23	.04	1.74	7.44	1.10	.17	1.13	4.78	.34	.12	.18									

It was found that from 15 to 19 per cent of the total protein could be extracted with water. Therefore when mushrooms are prepared for the table it is recommended that they be washed with small amounts of water.

For the digestion experiments the fungi were dried at low temperature and pulverized. They were mixed with water when fed. The rabbits were accustomed to the fungi by feeding them in increasing amounts with milk, sugar, and cocoanut cake. Three experiments are reported. In the first 20 gm. of *Agaricus deliciosus* was fed daily with water for 11 days. During the last 4 days the feces were analyzed. In the second test, which lasted 6 days, the rabbit received the same food as in the first with 8 gm. of sugar in addition. In the third test, which lasted 16 days, the rabbit was fed *Boletus edulis* with sugar. Tests were attempted with *Cantharellus cibarius*, but the rabbit would not eat this even with sugar. The first rabbit weighed 1,421 gm. at the beginning and lost 36 gm. daily, the second weighed 1,937 gm. and lost 23 gm. daily, and the third weighed 1,890 gm. and lost 10.2 gm. daily.

The results of the tests are shown in the following table:

Coefficients of digestibility of edible fungi.

	Dry matter.	Protein.	Fat.	Carbohy- drates.	Crude fiber.	Ash.	Albumin.	Amid nitrogen.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Rabbit 1.....	63.2	70.9	81.7	62.7	51.1	60.5	90.2
Rabbit 2.....	72.3	75.3	94.3	72.2	75.3	81.1	89.4
Rabbit 3.....	84.9	83.8	74.2	88.7	85.6	85.6	83.8	89.8

The addition of sugar increased the digestibility of the edible fungi.

The 3 varieties of edible fungi were digested with pepsin and pancreas according to Stutzer's method. It was found that 86 per cent of the *Boletus* was digested, 69 per cent of the *Agaricus*, and 58 per cent of the *Cantharellus*, while the coefficients by actual digestion experiments were 84.4, 70.9, and 75.3 per cent, respectively.

The author compares mushrooms with other food materials and believes that some of the earlier investigators have underestimated their food value.—P. FIREMAN.

Experiments on the nutritive value of alfalfa, A. MÜNTZ and A. C. GIRARD (*Ann. Agron.*, 24 (1898), No. 1, pp. 5-39).—The authors made an extended study of the composition of alfalfa. Experiments were made with 4 horses to determine the digestibility of alfalfa (green and cured) fed alone and of a mixture of alfalfa and meadow hay. In experiments 1, 2, 5, and 6 the effect of feeding equal and unequal quantities of hay was also studied. The digestion experiments were usually of 21 days' duration. The coefficients of digestibility of the different rations fed are shown in the following table:

Results of digestion experiments with horses.

Number of experiment.	Daily ration.	Coefficients of digestibility.							
		Protein.	Albuminoid nitrogen.	Material soluble in alcohol.	Material soluble in water.	Saccharifiable substances.	Sugar.	Crude fiber.	Undetermined substances.
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>

6	Horse 2..... 8.5 kg. alfalfa and meadow hay.	69.8	63.5	84.4	74.1	58.7	100	38.8	68.8
7	Horse 3..... 40 kg. alfalfa (green).....	75.2	72.4	89.1	92.2	62.5	100	46.0	75.4
	Horse 4..... do.....	81.2	79.2	90.2	92.7	66.4	100	47.6	75.9
8	Horse 3..... 10.5 kg. alfalfa hay.....	73.0	63.9	89.1	89.0	68.5	100	61.7	53.9
	Horse 4..... do.....	80.2	79.0	90.4	90.2	71.9	100	54.1	64.2

^a The mixed hay was composed of 68 per cent alfalfa and 32 per cent grasses.

The authors conclude that as regards nitrogenous material alfalfa is superior to meadow hay; as regards carbohydrates hay is superior. According to statistics for 1895 alfalfa furnished 162 kg. more digestible nitrogenous material per hectare than wild meadow hay. In addition the alfalfa fixes atmospheric nitrogen, while the grasses do not.

Investigation on molasses in different forms for fattening lambs, F. ALBERT (*Landw. Jahrb.*, 27 (1898), No. 1-2, pp. 208-211).—A test to compare different methods of feeding molasses was made with 4 lots of 15 lambs each. The test began June 22, 1896, and covered 206 days.

The average weight at the beginning was 30.58 kg. One lamb was dropped from the test before the close. All the lambs received a basal ration per 1,000 kg. live weight of 8 kg. alfalfa hay, 8 kg. straw and chaff, 6 kg. dried beef chips, and 5½ lbs. rape-seed cake. In addition, lot 1 was fed 1½ kg. molasses and 4½ kg. bran; lot 2, 9 kg. molasses bran; lot 3, 1½ kg. wheat bran and 6.69 kg. molasses peat (containing 4½ kg. molasses); and lot 4, 4½ kg. wheat bran and 11.15 kg. molasses peat (containing 7½ kg. molasses). In the case of lot 1 the molasses was either given in the drinking water or mixed with some other food. In the other cases a mixed molasses feed was used. All the rations furnished 3.49 kg. digestible protein; the first 3 furnished 16.05 kg. nitrogen-free material, and the last 18.21 kg. The cost of the rations for the different lots was as follows: Lot 1, \$52; lot 2, \$54; lot 3, \$53.15; and lot 4, \$55.86. The average gains for the corresponding lots were 268.5, 288.5, 278.5, and 286.5 kg.

The principal conclusions reached were the following: Molasses can be regarded as a rational feeding stuff for fattening lambs. The feeding value of molasses not mixed with other material is slightly less than that of the mixed molasses feeds. Molasses peat and molasses bran have the same food value, but (at current prices) the molasses-peat ration was somewhat cheaper. In the rations tested increasing the nitrogen-free material by the addition of a large amount of molasses was not profitable. The author discusses the financial returns with and without the value of the manure.

Influence of different protein compounds on the gain of flesh in swine, O. HAGEMANN (*Milch. Ztg.*, 26 (1897), No. 48, pp. 762-764).—The author calls attention to the fact that myosin (the chief nitrogenous constituent of flesh) contains 16 per cent of nitrogen, while the nitrogen content of the proteids in feeding stuffs varies, being, for instance, 18.2 per cent in case of peanut cake. In the author's opinion myosin can not be formed from the excess of nitrogen in proteids over 16 per cent. A method is proposed for calculating the amount of available protein in different feeding stuffs. Few details are, however, given.

Experiments were made with 8 pigs. From the time they were 8 weeks old until the beginning of the test proper the pigs were fed barley meal, consuming on an average during the 12 days 644 gm. and gaining 61 gm. in weight daily. The pigs were then divided into 4 lots of 2 each. Lot 1 was fed meat meal and potatoes; lot 2, corn meal and later ground oats; lot 3, barley meal; and lot 4, peanut cake and potatoes. In addition, all the lots were given salt, calcium phosphate, magnesium phosphate, and potassium chlorid, the amounts being in such proportion that the ash content of the different feeding stuffs was equalized. The amounts of food consumed, the nutritive ingredients, the total nutritive material, the nutritive ratio, and the gains in weight are recorded for the whole experiment, which lasted from August 14 to January 31. The total nutritive material was found by adding together

the protein, nitrogen-free extract, and fat multiplied by 2.5. The digestible nutrients consumed per day were calculated. The amount of digestible protein and total digestible nutritive material consumed per day and the gain in weight per gram of nutritive material in the several rations are shown in the following table:

Results of pig-feeding experiments.

	Food consumed.		Gain in weight per gram of nutritive material.
	Digestible protein.	Digestible nutritive material.	
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
Oats.....	157.2	1,278.7	0.3125
Meat meal.....	158.6	1,032.2	.2887
Peanut meal.....	156.9	1,074.1	.2574
Barley meal.....	153.9	1,081.4	.2387

The greatest gains were obtained with the oats. Of the other materials the total nutritive material consumed and the gain made was largest in the case of meat meal. Barley meal and peanut cake and potatoes were practically equal.

The pigs were slaughtered. The flesh of all the lots was of good quality and no differences were observed. This is of interest, since the opinion is more or less prevalent that the flesh produced by meat meal is of inferior quality. The author believes that if this is true it is due to the fact that the proper mineral salts are not fed with the meat meal. Meat meal contains an excessive amount of potassium salts. These are eliminated from the body and, it is said, remove considerable quantities of phosphoric acid and sodium. Therefore a corresponding amount of sodium chlorid and phosphoric acid salts should be supplied with the food.

Salicylic acid and calcium sulphite as preservatives of ciders, E. H. S. BAILEY and C. M. PALMER (*Kansas Univ. Quart.*, 6 (1897), pp. 111-116).

Observations on the nutritive value of "integral" whole-wheat bread, G. ALBINI (*Rend. Acad. Sci. Fis. e Math.*, 3. ser., 4 (1898), No. 3-4, pp. 117-120).—The author quotes at length the experiments of Pagliani and C. Mazza¹ on the digestibility of the so-called integral whole-wheat bread, made by Desgoffe and Avedyk's method without grinding the grain. It is believed that the results indicate that while the bread can be recommended on account of its price it is not a suitable article of diet on account of its inferior digestibility.

"Integral" whole-wheat bread, A. CELLI (*Uffice. Sanit.*, 11 (1898), No. 3, pp. 121-127).—The composition of bread made directly from grain without grinding (according to Desgoffe and Avedyk's method) is reported as follows: Water, 46.30 per cent; protein, 13.88 to 14.22; fat, 1.11 to 2.39; starch, 77.12 to 77.32; crude fiber, 2.6 to 3.12; ash, 3.49 to 3.85; and acid, 1.8 to 2.1 per cent. The author considers the bread inferior on the basis of composition, physical properties, indigestibility, and lack of keeping qualities.

Feeding stuff inspection, C. D. WOODS (*Maine Sta. Bul.* 44, pp. 16).—In compliance with the Maine feeding-stuff law determinations were made of the protein and

¹ La panification integrale col sistema Antispere (Desgoffe et Avedyk), Torino, 1898.

fat in a number of samples of cotton-seed meal, linseed meal, gluten meal, gluten feed, oat feed, meat meal, meat scrap, and mixed feeds. The law is regarded as successful, and statements are made concerning its operation.

Report of the dairy and food commissioner, L. WELLS (*Pennsylvania Dept. Agr. Bul. 34, pp. 108-118*).—A report is given showing the satisfactory working of the pure-food law in Pennsylvania. The subject is discussed chiefly from a legal standpoint.

Data on the growth of young stock, C. C. GEORGESEN, F. C. BURTIS, and D. H. OHS (*Kansas Sta. Bul. 72, pp. 175-180*).—Notes are given on the growth of the young cattle in the station herd during the winter of 1897. The amounts of food consumed and gains made by 12 Shorthorns, 4 Holstein-Friesians, 3 Herefords, and 5 Jerseys are recorded. No conclusions are drawn from the work.

DAIRY FARMING—DAIRYING.

Investigations on the composition of colostrum with special reference to the proteids, H. TIEMANN (*Ztschr. Physiol. Chem., 25 (1898), No. 5-6, pp. 363-392*).—Analyses are tabulated of the colostrum from the first 3 milkings of 2 Angler, 1 Breitenburger, 1 Shorthorn-Dithmarsch, and 2 native cows. The methods employed are described, and, incidentally, a comparison is given of the Wollney refractometer with gravimetric analysis for fat.

The results show that the colostrum of different cows varies widely in composition. The solids ranged from 12.83 to 32.93 per cent, decreasing from one milking to another, while the water increased. The greatest variation was found in the fat, which ranged from 0.56 to 9.28 per cent. The total proteids varied from 13.25 to 21.76 per cent for the first milking, from 7.74 to 15.80 for the second, and from 4.66 to 12.06 for the third, thus decreasing rapidly from milking to milking. The sugar content, on the other hand, increased, varying from 1.63 to 2.92 in the first milking, from 2.37 to 3.88 in the second, and from 2.74 to 4.39 in the third. The ash showed little change from one milking to another. Comparing the results with those given by others, the author concludes that breed has little to do with the composition of colostrum, but that it is a matter of individuality.

Most of the paper is devoted to the proteids of colostrum. The literature of the subject is reviewed, showing the prevalence of a diversity of views on the nature of the proteids, some investigators asserting the absence of casein and that only albumen is present, while others claim that both casein and albumen are present, although they differ considerably as to the relative amounts of the two. Sebelin¹ and Emmerling² have also reported the presence of a globulin in colostrum.

The author's investigations were made on colostrum from the first 3 milkings of the cows mentioned above. Separations were made by means of the porous plate and by various chemical means. He concludes that the content of total proteids differs widely and dimin-

¹ *Ztschr. Physiol. Chem.*, 13 (1889), p. 171.

² *Centbl. Agr. Chem.*, 17 (1888), p. 861.

ishes from milking to milking. The undissolved albuminoids (those in suspension) are 10 to 30 times and in some cases 100 times as great in amount as those in solution.

The undissolved albuminoids decrease regularly, while the dissolved albuminoids show less variation and usually increase in amount. Assuming the proteid in solution to be albumin, the amount found in colostrum was approximately the same as that present in normal milk, and this was borne out by direct determinations of the albumin.

Both the casein and globulin are present in colostrum in suspension, i. e., not in solution. The casein was usually within the limits for normal milk, although sometimes slightly greater. The globulin content was invariably in excess of the casein, being from 2 to 4 times as great. The curdling which takes place on heating colostrum is principally due to the globulin, which coagulates at 72° C. Analyses of the preparations of the globulin showed it to contain 49.83 per cent of carbon, 7.77 of hydrogen, 15.28 of nitrogen, 1.24 of sulphur, and 25.88 of oxygen, from which the author concludes that it is not identical with any known albuminoid. It is soluble in dilute acetic acid and dilute salt solution, is coagulated from the same by heat, and is precipitated from a dilute salt solution by saturation with salt, showing it to be a globulin-like substance. Hence the author proposes to call it colostrum globulin. The marked difference in composition between it and blood globulin indicates that blood globulin, like most other constituents of the blood, does not pass into the colostrum in its original form but is materially altered in the lacteal glands.

Goats' milk and goats' colostrum, R. STEINEGGER (*Schweizer Bauer; abs. in Milch Ztg., 27 (1898), No. 23, pp. 356-358*).—A study of the normal milk and especially the colostrum of goats, made at the dairy school at Rütli. The normal milk of goats of the region was found to contain: Water, 88.42 per cent; fat, 3.25; albuminoids, 3.92; milk sugar, 2.80; and ash, 0.63.

It is stated that the colostrum varies greatly with individuals of the same breed. Some goats give no real colostrum and others only a very little. Analyses are given of the milk of a goat with her first kid, showing that there was practically no change in composition during the first 4 days after parturition. "The milk was entirely normal from the first, and there was no true colostrum." The third milking of another goat showed colostrum bodies under the microscope, and was high in fat (6.1 per cent). The first milk of an older goat did not have the composition of colostrum, although the acidity was high; but that from the second milking contained 16.85 per cent of fat; the next day it had fallen to 4.2, and 2 days later was normal.

Concerning the composition of milk produced in the vicinity of Giessen, T. GÜNTHER (*Milch Ztg., 27 (1898), No. 29, pp. 453, 454*).—In a study of the milk supply of Giessen, Germany, the author analyzed the milk from 130 producers, representing the milk of 441 cows. The

samples were taken in August and September and in March and April. The range and the average composition of the 130 samples of milk were as follows:

Composition of milk sold in Giessen.

	Range.		Average composition.
Specific gravity.....	1.0277 to	1.0345	1.03086
Total solids.....per cent..	11.3	15.0	12.55
Fat.....do.....	2.6	5.8	3.83
Solids-not-fat.....do.....	7.9	9.9	8.72
Fat content of solids.....do.....	22.6	40.2	30.52

The fat content was 3.5 per cent or over in more than two-thirds of the cases and 4 per cent or over in 35 per cent of the cases. On the basis of the investigation, a specific gravity of from 1.028 to 1.0345 and a fat content of 3 per cent are recommended as the milk standard for whole milk for the city.

Abstract of the report of the experiment station and school at Kleinhof-Tapiau for 1897-98 (*Milch Ztg.*, 27 (1898), No. 32, pp. 500-502).—Among other things the report contains the results of a test of Wolny's refractometer and the Gerber and Babcock milk tests. The results of the examination of the milk of the Kleinhof-Tapiau herd from 1889 to 1897 (E. S. R., 7, p. 50) are briefly discussed in the abstract, and a summary is given for the year ending September 30, 1897. Data are given as to the yield of different kinds of cheese from whole milk and from skim milk, the losses in ripening different kinds of cheese, etc.

A method for distinguishing pasteurized and unpasteurized milk, V. STORCH (40. Bericht des Versuchslaboratoriums der Kgl. Veterinär- und Landbauhochschule. Copenhagen: A. Bang, 1898; abs. in *Milch Ztg.*, 27 (1898), No. 21, pp. 374, 375).—In Denmark the laws for the suppression of tuberculosis forbids the selling of skim milk or buttermilk which has not been heated to at least 85° C. It was for the execution of this law that Professor Storch devised his method. The method is based upon Babcock's discovery that the fibrin of milk decomposes hydrogen peroxid, that cream is more active in this respect than whole milk, that skim milk is less active, and furthermore that milk heated to 100° loses this property. Storch found that milk retained its property of reducing hydrogen peroxid up to 79° C. As an indicator of the reduction he uses paraphenyldiamin.

The hydrogen peroxid solution is made by diluting the commercial article (when it contains 1 per cent of the material) with 5 times its volume of water and adding 1 cc. of concentrated sulphuric acid per liter. In making the test a teaspoonful of the milk (cream or whey) is shaken in a test tube with a drop of the peroxid solution and 2 drops of the paraphenyldiamin solution. If the milk colors immediately (milk or cream, indigo blue; whey, violet red brown) it has not been heated to 78° C., and in fact has not been heated at all. If the milk or cream becomes grayish blue immediately or in half a minute, the indi-

cation is that it has been heated to 79 or 80°, and if it retains its original white color or is colored only slightly violet red it has been heated to more than 80°.

In testing sour buttermilk a teaspoonful is neutralized with lime-water and then the peroxid and indicator added. If the mixture turns blue the indication is that the cream from which the buttermilk originated was not heated to 80° C., but if no color appears it has been heated to 80° or more.

In testing butter about 25 gm. is melted in warm water, the clear butter fat poured off, and the milky residue adulterated with a like volume of water. The mixture is then tested in the same way as milk. If a blue color appears the conclusion is that the cream from which the butter was made was not heated to 80° C., but if there is no color or a weak violet brown color the butter was made from pasteurized cream.

Accompanying Storch's paper is a colored plate showing the colors of the reactions with pasteurized and unpasteurized milk, cream, skim milk, and whey.

A new method of preserving milk, H. DE LAVALLÉE (*Abs. in Milch Ztg.*, 27 (1898), No. 30, p. 472).—Directly after milking the milk is placed in a cooled vessel and treated to pure carbonic acid under pressure of 5 to 6 atmospheres for 4 or 5 hours. Following this it is treated to oxygen at 5 atmospheres for 5 hours. This treatment kills all the aerobic and anaerobic bacteria. The milk is transported in vessels containing oxygen under 2 atmospheres of pressure. These vessels may be made in the form of siphons. Milk treated in this way is said to retain all the properties of fresh milk and can be guaranteed to be entirely free from all diseased germs.

Factory tests for milk, S. M. BABCOCK, H. L. RUSSELL, and J. W. DECKER (*Wisconsin Sta. Bul.* 67, pp. 20, figs. 6, pl. 1).—The statement is made at the outset that "every cheese factory, whether conducted upon the relative value plan or not, should be equipped with suitable apparatus for determining the cheese value of milk, and no one should be considered competent to manage a factory unless he knows how to use such apparatus." The use of the milk tester and lactometer for determining the composition of milk is described, and attention is called to the fact that the cleanliness and bacteriological condition of the milk, which are frequently overlooked, are matters of no less importance in cheese making than the composition.

"If the milk contains micro-organisms that are capable of decomposing any of the cheese-producing substances or is impregnated with taints or obnoxious flavors that are absorbed from the animal or after the milk is drawn, then its theoretical value as based upon the nutritive worth of its various elements is diminished to a greater or less degree by the operation of this second factor. So far the value of milk has been entirely determined by its cheese-producing capacity, and the influence of biological factors (bacteria, etc.) upon the character of the product has been ignored. . . . The actual value of any milk may be materially modified by the presence of taints (actual or potential), and to detect these is a very necessary and essential part of the cheese maker's business."

The testing of milk by its taste and odor, the detection of foreign matter by allowing a sample to stand in a glass jar and observing the amount of sediment, and testing the acidity by Farrington's alkaline tablets (*E. S. R.*, 6, p. 83; 8, p. 933) are discussed, as are also the use of the rennet test, the detection of antiseptics, and fermentation tests. Gerber's fermentation test, as a means of determining approximately the quality of milk, is described. The more important feature of the bulletin is the description of the Wisconsin curd test, which originated at the Wisconsin Dairy School in 1895. An illustrated description of this test and the method of conducting it and interpreting the results are given.

To make the test a fruit jar is filled half full of milk and set in a tub about half full of water sufficiently warm to raise the temperature of the milk to 98° F. When this temperature is reached 10 drops of rennet extract is added to the milk and the jar left undisturbed until the milk is curdled, when the curd is broken into small pieces by stirring with a case knife. The whey is poured off as soon as the curd settles, and this process is repeated at frequent intervals until the curd mats into a solid mass. The temperature of the surrounding water should be maintained from 6 to 8 hours, to favor the rapid development of the organisms in the curd.

"If the milk contains no deleterious bacteria, the curd when cut will present a firm, even texture. If gas-producing bacteria are present the texture of the curd will be more spongy, the cut surface showing a number of holes varying in size, depending upon the prevalence and gas-producing ability of the undesirable bacteria. . . . The conditions under which the curd test is conducted accelerate the fermentative action, so that a milk that might show no symptoms of gas formation until the cheese was on the shelf would be detected when subjected to the curd test. Milks that are sufficiently contaminated to produce floating curds will show a very spongy texture in the test in a few hours. No hard and fast rules can be given for the interpretation of the results of the curd test, but an ordinary operator will very quickly learn to discriminate between milks that should and should not be accepted. . . . It is also possible that taints may be produced by bacterial decomposition in cases where no gas is formed. This is particularly true with that class of organisms that act upon the albumen and casein instead of the milk sugar. Those bacteria that find their way into the milk through the introduction of filth and dust are particularly prone to produce this change, and this type of fermentation is very often found during the summer months. In the curd tests such milks are not condemned upon the texture of the curd, but upon the odor, which is more or less pronounced when the bottle is opened."

Besides the improvised apparatus for making the test an improved apparatus is described, consisting of a water box with a close-fitting cover which permits the retention of the desired temperature for a longer time, racks for holding the bottles, and bottles better suited to the purpose of the test than ordinary fruit jars. Such apparatus can now be obtained of some of the dairy supply houses.

In conclusion, several illustrations are given of the favorable results which have followed the use of the curd test in cheese factories. In one case where the cheese maker was troubled with tainted milk

and pin-hole curds the test showed that the bad milk could be traced to 6 different sources where carelessness prevailed in caring for the milk. The trouble was overcome when the fault was located. In another factory, where brick cheese was made and the quality of the product was so poor that the cheese had fallen off 3 cts. per pound in value, the curd test narrowed the trouble down to 3 cows that gave gassy milk. When the milk of these 3 cows was excluded the trouble disappeared at once. In another brick-cheese factory where similar trouble occurred "the curd test of each patron's milk revealed the fact that in 6 out of 28 cases bad milks were being brought to the factory." When the milk from these patrons was excluded good cheese was produced. An extract is given from the report of the traveling dairy instructor of the Wisconsin Dairymen's Association to the effect that the test "will locate tainted milk with unerring certainty," and "is simple, practical, reliable, and very convincing."

Contribution on rennet curdling, R. BENJAMIN (*Inaug. Diss., Berlin, pp. 32*).—The author made investigations on the action of rennet on the casein of milk in the presence of foreign substances or in the case of milk treated in different ways, the action of rennet to which chloroform was added, and the action of rennet on other animal and vegetable albuminoids.

Milk with an acid reaction curdled most rapidly, that with a neutral reaction more slowly, and a too strongly alkaline solution prevented curdling altogether. Milk to which chloroform was added curdled somewhat more slowly, and milk diluted with water even more slowly. Boiled milk refused to curdle with a strong rennet solution, but was curdled by rennet powder in 5 minutes. It was found impossible to curdle sterilized milk by any means. The addition of chloroform in very small quantities in making up the rennet solution was found to increase the curdling action of the rennet, while large quantities diminished it. No animal or vegetable albuminoid, except the casein of milk, was found to be acted upon by rennet. All solutions of casein which curdled with rennet were found, like milk, to be alkaline toward laemoid and acid toward phenolphthalein; and casein solutions were not curdled except in the presence of soluble lime salts.

Further contributions on milk hygiene, OTT (*Ztschr. Fleisch- u. Milchhyg., 8, No. 4, pp. 69-74*).—The author discusses the danger of infection with tuberculosis from using raw milk. Forty-three samples of market milk were examined for tubercle bacilli by treating 25 cc. of milk with 2 cc. of caustic ammonia and 100 cc. of a mixture of ether and petroleum ether in equal parts, removing the fat layer, and then treating the remainder of the solution in a centrifugal apparatus for 15 minutes. The sediment was then examined in the ordinary manner. Of the 43 samples of milk tested 5 were found to contain the bacilli, the number of bacilli in 4 cases being small.

To test the virulence of the bacilli guinea pigs were inoculated with

5 cc. of a mixture of the sediment and cream. Of 10 animals inoculated 7 became infected with tuberculosis. Fresh milk obtained from dealers was inoculated into 30 guinea pigs, with the result that 10 died, 4 dying from the effects of tuberculosis.

The author discusses the results as pointing to the danger of infection from tuberculosis, strongly advises sterilizing milk on a commercial scale and in the home, and points out the desirability of veterinary control of dairy herds. The testing of milk for disease germs is believed to be quite as important as the ordinary milk control in which the fat content or addition of water is determined. The author regrets the lack of a rapid and safe method by which tubercle bacilli can be detected in milk, making it practicable to exclude from sale milk containing the bacilli.

The recognition of tubercle bacilli in butter and milk (*Arb. K. Gesundheitsamte, 11, No. 1; abs. in Milch Ztg., 27 (1898), No. 35, pp. 551, 552*).—In the examination of 102 samples of butter, using guinea pigs for experimental animals, a new rod bacillus, very similar to the tubercle bacillus, was found. This bacillus, it is stated, might easily be mistaken for the tubercle bacillus, especially by an inexperienced observer. Of the 102 samples of butter, 17 contained tubercle bacilli alone, 16 contained tubercle bacilli and the new rod bacillus, 38 contained the new bacillus alone, and only 17 were free from both bacilli.

The new bacilli did not cause sickness in guinea pigs except when present in large quantities. The effect was more marked when the bacilli were taken with large quantities of butter, in which case the effect on the peritoneum was very similar to that produced by tubercle bacilli and butter, the animals dying in both cases with similar symptoms.

Of 64 samples of milk collected from milk wagons and dairy stores in Berlin, 9 contained tubercle bacilli, 4 contained the new bacillus, and 51 were free from either kind of bacilli. It is thought possible that the new bacillus may have been overlooked in some of the earlier samples examined.

Milk supply from a bacteriological standpoint, P. RAVENEL (*Jour. Comp. Med., 1898, No. 4, pp. 215-221*).

On the ripening of cheese, J. SCHIVOKICH (*Ann. Inst. Pasteur, 12 (1898), No. 6, pp. 400, 401*).

Dairy department, E. E. KAUFMAN (*North Dakota Sta. Rpt. 1897, pp. 80, 81*).—A brief account of the work of the dairy department of the station.

On the fungus flora of Brie cheese, J. CONSTANTIN and J. RAY (*Compt. Rend. Soc. Biol., 1898, No. 16, pp. 504-507*).

Micro-organisms in the dairy, N. BENDIXEN (*Die Mikroorganismen im Molkereibetriebe. Berlin: 1897, pp. 44; abs. in Hyg. Rundschau, 8 (1898), No. 11, p. 548*).

The mechanical purifying of milk and apparatus for this purpose, A. LAVALLE (*Milch Ztg., 27 (1898), No. 25, pp. 390-392, figs. 7: 26, pp. 405, 406, figs. 10: 27, pp. 417-419, figs. 5*).—The article describes various forms of centrifugals, strainers, filters, and apparatus for sedimentation for cleaning milk on a large and small scale.

Extracts from the report for 1897 of the Dairy Institute at Hameln (*Milch Ztg., 27 (1898), No. 23, pp. 354-356*).—Data are given as to the efficiency of separators, the losses in butter making, testing of skim milk by Gerber's apparatus, etc.

On iodin fat and its behavior in the body, H. WINTERNITZ (*Ztschr. Physiol. Chem.*, 24 (1898), No. 5-6, pp. 425-448).—Among other things experiments are reported with goats on the transmission of iodin fat in the food to the milk of the animal. When iodin fat was fed it was detected in the milk, being absorbed by the milk fat.

Asses' milk as a substitute for human milk, A. SCHLOSSMANN (*Abh. in Milch Ztg.*, 27 (1898), No. 25, p. 393).—The variations in asses' milk, the relative proportions of its constituents as compared with human milk, and the nutrition of the child with asses' milk are considered.

The conditions of the production of richer milk, A. KRAEMER (*Milch Ztg.*, 27 (1898), No. 26, pp. 402-404).—A concise summary of the results of investigations relating to the effect of feeding and management on the yield and composition of milk.

Bacteriology in the dairy, E. VON FREUDENREICH (*Jena: Gustav Fischer, 1898*).—This is a short popular treatise on this subject for the use of dairy schools, cheese makers, and farmers. The book is very favorably mentioned in *Milch Zeitung*, 27 (1898), No. 24, p. 378).

VETERINARY SCIENCE AND PRACTICE.

Cattle tick and Texas fever, W. H. DALRYMPLE, S. B. STAPLES, H. A. MORGAN, and W. R. DODSON (*Louisiana Stas. Bul.*, 51, 2. ser., pp. 230-282, pls. 5, figs. 2).—The widespread dissemination of Texas fever is pointed out and the symptoms of the disease are described in detail.

"A summary of the more diagnostic characters to be looked for when Texas fever is suspected would include:

"(1) Cattle ticks; (2) hæmoglobinuria, enlarged spleen, enlarged yellowish liver, thick flaky bile, extravasations on the outer and inner surface of the heart, and (3) reduction in the number of red corpuscles, thinness of the blood, and the tardiness with which it exudes from an incision."

The life history of the southern cattle tick is discussed at some length and a number of experiments on the condition of development of the tick and on the efficacy of serum treatment for cattle are reported. Following is the authors' summary:

"The development of the cattle tick is less rapid in winter than in summer. The period of incubation is influenced by cold, and egg fertility is destroyed by direct sunlight. Seed ticks are capable of living a considerable length of time without food; this period is less in summer than in winter. Seed ticks may endure cold down to 16° F., below which death takes place. The parasitic period of development of the tick is very much longer in winter than in summer. The cattle tick remains attached to animals from the seed-tick stage to adult condition; if removed from its host during this parasitic period it soon perishes. The adult female tick is more easily destroyed by rainfall and cold than any of the other stages. The conditions lessening the number of broods per season also aid hibernation. Clean pastures materially aid disinfection. Ticks will not exist upon alluvial pastures unless the pastures are constantly being reinfected by the importation of highland cattle. Pastures may be disinfected by removing all cattle from them for at least one year, as would be the case in a system of rotation of crops. Ticks may be removed from animals by the use of mineral oil, applied either with a sponge or rag, or by plunging animals into a vat containing water upon the surface of which floats a thin layer of oil. Herds may be improved by keeping an imported stock bull in a small disinfected pasture or in a stable. The offspring of this animal will either possess immunity from birth or acquire it very young. The injection of 2 cc. of serum for

each 100 lbs. of the animal's weight, given daily for 10 days before ticks are allowed to get on the cow, will not prevent the animal from taking Texas fever. The injection of a moderate amount of serum for 10 days, beginning the treatment about the time the animal becomes infested with ticks, does not prevent the development of Texas fever. The injection of a large quantity of serum after the fever has developed does not influence the temperature of the animal."

Acclimation fever, or Texas fever, J. C. ROBERT (*Mississippi Sta. Bul. 12, pp. 32, figs. 1*).—Texas fever is discussed and the fact pointed out that so far as is known the only natural means of infecting cattle with this disease is the cattle tick. The cattle tick is described at some length. Quarantine regulations against Texas fever and the value of dipping cattle are discussed at some length.

A number of experiments were made with blood serum as a preventive and cure for Texas fever. The serum used in the experiments was obtained from southern cows well covered with ticks. The blood was taken from the jugular vein and collected in sterilized jars. After standing for 36 hours on ice the serum was drawn off in sterilized glass bottles. A small amount of serum was also prepared from a southern cow free from ticks. Tests were made to determine the efficiency of inoculation (1) before shipping cattle South, (2) before shipping and after reaching the South, (3) using serum from cattle with and without ticks on them, (4) with serum from cows sick with Texas fever, and (5) with tick juice. The various experiments are described in detail.

"The results of the experiments indicate unmistakably that the blood serum inoculation as we practiced it had no effect either in preventing or curing Texas fever. Our experiments furnish us additional evidence, however, that the cattle tick is the agent for transmitting the disease, and that valuable breeding animals can be brought South at any time with little danger of contracting 'acclimation' fever, provided they are kept free from ticks by placing in uninfected inclosures. Such animals should be regularly and carefully examined for ticks and the legs and soft skin of the body occasionally oiled."

The author is of the opinion that there is no toxin produced by the Texas-fever germ.

The typhoid serum diagnosis, H. L. BOLLEY (*North Dakota Sta. Rpt. 1897, pp. 30-43, fig. 1*).—The author gives a popular account of the subject, briefly mentioning the work of a number of investigators. Original investigations are also reported on the effects of typhoid serum upon the bacilli, the variation in condition as affecting the reaction, the use of the reaction in water analyses, and the source of reaction serum for the last purpose. The effects of the serum upon bacilli as seen under the microscope are described in some detail.

Experiments made during 1895-96 on the bacterial content of milk in the udder are noted. The following conclusions were drawn: The number of germs in the same udder varies at different times. The number varies on the same day in the different teats of the same udder, and on the same date for different udders. The number of different species present is also found to vary, and there is little constancy of

species in common to a number of different cows. Some species when once in a particular teat tend to occupy it with considerable persistency. The species able to multiply within the milk passages appear for the most part to be of the lactic-acid producing type.

An investigation of the growth of germs of typhoid fever in milk, butter, and other food products is also briefly noted. The injection of cultures of typhoid germs in butter into the abdominal cavity of guinea pigs resulted in death with typical symptoms and *post-mortem* characteristics of typhoid.

Larkspur poisoning of sheep, E. V. WILCOX (*Montana Sta. Bul.* 15, pp. 37-51, pls. 3).—Losses of stock by eating poisonous plants have been reported for many years in Montana. Such losses have been most frequent during May and June, but have been noted at other seasons. The poisoning has been attributed to various plants. The author investigated widespread cases of sheep poisoning, which occurred in May, 1897. About 2,000 yearling lambs were moved to a new grazing region and almost immediately several of the sheep were taken sick. In a few days the sickness became widespread and the mortality was very great. From *post-mortem* examination it was evident that death was due to asphyxia or oxygen starvation, as the result of some sedative poison which had paralyzed the respiratory centers of the nervous system and prevented the proper action of the lungs in the purification of the blood. In the stomach contents were found the leaves and roots of a species of larkspur (*Delphinium menziesii*). The plant was found to occur plentifully in certain portions of the range. It was confined to the banks of streams and was not found on the higher ground. It was noticed that the poisoning occurred after the sheep had been feeding along streams where the larkspur was abundant.

“The symptoms shown by sheep poisoned by larkspur have a general resemblance to those of aconite poisoning, but are somewhat different in several particulars. The first signs of the poisoning are a slight general stiffness and a straddling gait, especially of the hind legs. The stiffness becomes more and more pronounced until walking is quite difficult and evidently painful. Soon there are manifested various involuntary twitchings of the muscles of the legs and sides of the body. There is a loss of control or co-ordination of the muscles. There is ordinarily no increase in the quantity of the saliva, no dribbling of saliva from the mouth, no champing of the jaws or attempts at swallowing. The sheep manifest none of the mental disturbances frequently seen in cases of poisoning from other sources, as, for example, loco weed and lupine. There is no impairment of the special senses. The sheep seem to hear and see as well and as correctly as under normal conditions of health.

“No indications of any disturbances of the digestive functions are to be seen. The appetite remains good, and the sheep eat up to the very last. They were observed eating industriously during the intervals between the attacks of spasms which they have during the last stages.

“At first the frequency of the pulse and of the respiratory movements is lessened and the temperature is lowered. The pulse remains very weak, but in the later stages becomes very rapid, in some cases 130 per minute. Toward the last, also, the respiration is very shallow and rapid. During the final convulsions the respiration is sometimes 120 per minute, but so shallow that the air is simply pumped up and

down the windpipe. The air in the lungs is therefore not renewed and the animal dies by asphyxia or suffocation.

"As long as the sheep can stand on his feet, or walk, he keeps up with the herd as nearly as possible. The exercise, however, excites him, makes his respiration more rapid, and he has frequently to lie down for a moment and then get up and hobble along after the herd. The worst cases can thus easily be detected, since they straggle behind the rest of the herd.

"The later stages of the poisoning follow rather rapidly. The involuntary movements become more frequent and more severe. All four legs tremble and shake violently. In fact all the muscles of the body contract spasmodically until the animal totters over on his side and dies in the most violent spasms."

The similarity to aconite poisoning suggested the line of treatment followed. Bleeding gave no relief and lard given internally had no noticeable effect. When only small amounts of larkspur had been taken the administration of ammonia or alcohol was found to give good results. During the first stages 3 drams of ether given through the mouth had good effect and later $\frac{1}{2}$ dram of ether given hypodermically stimulated the action of the heart and respiration. The most effective remedy was hypodermic injections of a solution of atropine sulphate in camphor water (4 grains of atropine to 1 fluid ounce of camphor water). Doses of 40, 30, and 20 minims of the solution were used, equivalent to $\frac{1}{3}$, $\frac{1}{4}$, and $\frac{1}{5}$ of a grain of atropine sulphate. The solution was injected in the region of the shoulder. The effect was almost immediate. With one exception all the sheep treated by this method recovered. In the later convulsive stages of poisoning, ammonia fumes under the nostrils proved beneficial.

"Care in the management of sheep after they are poisoned is quite as important as the giving of medicines. Sheep poisoned with larkspur should be kept as quiet as possible. A trifling fright or excitement may throw them into spasms, and thus result fatally. From the very first the poisoned sheep have considerable difficulty in keeping up with the rest of the herd. They have a stiff and trembling gait. It becomes necessary for them frequently to stop for a moment to rest. In this way they repeatedly fall behind the herd and then run to overtake it again. Thus their excitement is constantly increased until they fall down in spasms.

"As soon as the stiffness and straddling gait, which are the first symptoms of larkspur poisoning, are noticed, one or the other of two methods of procedure should be adopted. Either the whole band of sheep should be herded closely and prevented from moving as fast as it usually moves, or, what is perhaps still better, the poisoned sheep should be separated from the others and kept as quiet as may be."

The author reports 2 experiments with sheep in which chloroform and benzol extracts of larkspur were injected.

"After 15 minutes the lambs began to show symptoms of larkspur poisoning and at the end of 1 hour the symptoms were so plain and pronounced that it was considered useless to sacrifice the lambs to the experiment. Both were therefore given one-eighth of a grain of atropine, which, with the aid of a small dash of ammonia in the nostrils, counteracted the effects of the poison and the lambs recovered completely.

"These experiments are quite in accord with the conclusions reached in the field work, and furnish another strong piece of evidence to the correctness of those conclusions, not only as to the cause of the poisoning but as to remedies to be used."

According to the author 2 species of larkspur are found in Montana, *Delphinium menziesii* and *D. glaucum*. Both these species are described.

The gape disease of poultry, H. GARMAN (*Kentucky Sta. Bul. 70, pp. 107-112, pls. 2*).—The author discusses this disease of poultry, which is caused by the presence of the gapeworm (*Syngamus trachealis*) in the trachea or windpipe, and the remedies commonly employed.

An experiment was made to learn the cause of the disease. Twenty chickens were divided into 2 equal lots immediately after hatching. They were placed in pens separated by wire netting. In one case the pen had a raised floor and in the other case the chickens ran upon the ground. The 2 lots were fed corn meal mixed with water and scraps of bread, potato, and meat from the table, with a few oats in addition. The chickens running on the ground were also fed earthworms. At the beginning of the test 3 of the chickens running on the plank floor managed to get through the wire netting into the other pen and were allowed to remain there. One of the chickens in the pen without a floor died from an unknown cause at the beginning of the test. About 2 weeks after the trial began one of the chickens in the lot running on the ground was badly affected with gapes, and several others were slightly affected. Sooner or later all the chickens in this lot were affected with gapes and either died or were destroyed, while in the other lot there were no cases. The author concludes that the chickens acquired the gapeworms either from the ground or from the earthworms fed to them.

Earthworms a source of gapes in poultry, H. GARMAN (*Kentucky Sta. Bul. 71, pp. 71-73*).—In continuation of the above work a test was made with 6 chickens divided into 2 equal lots. They were kept in wooden cages with wire gauze sides. One lot received earthworms and the other cooked meat in addition to the regular ration. The earthworms were thoroughly washed to prevent the adherence of soil or gapeworms. The chickens fed earthworms became affected with gapes. One of the chickens in the lot fed meat died from a bowel trouble, but examination failed to reveal any gapeworms. The 2 remaining chickens in this lot were alive at the time the test was reported and had not shown any symptoms of the gapes.

The conclusion is reached that earthworms convey the gape disease to poultry, and the common practice of feeding them to young chickens is condemned.

The inspection of meats for animal parasites, C. W. STILES and A. HASSALL (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 19, pp. 161, figs. 124*).—The bulletin consists of three parts: (1) The flukes and tapeworms of cattle, sheep, and swine, with special reference to the inspection of meats, by C. W. Stiles; (2) compendium of the parasites arranged according to their hosts; and (3) bibliography of the more important works cited, by A. Hassall.

"Although the report is intended primarily for the use of the meat inspectors of this Bureau, it will be found of general interest to all sanitarians, since it treats of the communicability of certain parasites from animals to man, and suggests the necessary methods of prevention and treatment therefor. The bulletin will serve a useful purpose in disseminating knowledge of the precautions that are required to eradicate certain of the most important parasites affecting domesticated animals in this country—parasites which are a menace to the public health. There is no work in the English language covering the subjects of which it treats."

In describing the different animal parasites technical zoological details have for the most part been omitted, stress being placed upon the practical application of zoological knowledge to questions of public hygiene. The authors call attention to the fact that the most important parasites for American inspectors are the common liver fluke and the large American fluke (which are a serious menace to live stock), beef measles, pork measles, and Hydatids, all of which bear an important relation to diseases in man. As noted, the Hydatid disease is comparatively rare in this country, and methods should be taken at once to prevent its spread.

"By proper precautions at the abattoirs and slaughterhouses this dangerous parasite can be totally eradicated from the country. If these precautions are not carried out it will only be a question of time when this country will take its place with Germany and Australia in respect to the number of human lives sacrificed to a disease which has not yet gained much ground with us and can now be easily controlled."

A complete index adds to the value of the bulletin.

Special investigation of the so-called "new horse disease" in Maryland. S. S. BUCKLEY (*Maryland Sta. Bul.* 53, pp. 110-111).—The author identified a so-called new horse disease prevailing to a considerable extent in Worcester County, Maryland, as cerebro-spinal meningitis. The disease is described, and information on its cause, treatment, and prevention is summarized.

"On the first appearance of this disease upon a farm a complete change should be made in the food. All moldy grain or fodder should be rejected, and where possible wheat bran should form part of the ration.

"It is evident that in so severe and rapidly fatal a malady powerful agents must be used. Proper nursing is necessary for success. Without it medicines avail but little. Placing the animal in slings early acts very beneficially in preserving the strength and increases the chances of recovery. When there is any considerable degree of heat at the poll of the head we should resort to the constant application of cold water, crushed ice, or some cooling lotion (nitrate of potash and acetate of ammonium, each a teaspoonful to a gallon of water). In the early stages these tend to check the flow of blood to the brain, and therefore reduce pressure upon it. Among medicinal agents we have recourse to ergot, aconite, and belladonna. Nux vomica and strychnin seem to be capable of producing desirable effects. As all of these are extremely powerful and poisonous, they should be used where possible under the supervision of a veterinarian, so that their effects may be watched and their omissions ordered, if necessary. The appetite should be maintained with tempting foods and drink. Purgatives and bleeding are to be avoided, as they seem to prove disastrous after the symptoms have become fully established. When the crisis has been passed and the animal begins to take nourishment tonics containing quinin and nux vomica should be given."

Dehorning cows, G. M. GOWELL and F. L. RUSSELL (*Maine Sta. Bul. 11, pp. 8*).—The opinions of a number of investigators concerning dehorning cattle are quoted and the results reported of dehorning at the station with clippers, and in the case of calves by means of potash. Dehorning is recommended, and it is believed that cattle are more comfortable and may be more easily cared for without horns than with them. Other conclusions are the following:

“The best time to dehorn cattle is during cold weather when there will be no trouble from flies.

“To dehorn mature animals, clippers should be used that will remove the horn perfectly at a single stroke and in a moment of time. With suitable clippers properly used the operation is simple and very quickly performed. When it is skillfully performed, animals do not give evidence of great suffering as an effect of dehorning. The tissues injured in dehorning are not very well supplied with nerves and they are quickly cut through. Good evidence that dehorning is not very painful is the fact that cattle will resume feeding immediately after being operated on, and the yield of milk in cows is not perceptibly affected. Compared with castration of colts and calves, dehorning may be considered painless. . . .

“To prevent the growth of horns, calves under 3 weeks of age can have the embryonic horns removed with one stroke of a sharp knife, or they can be treated with a caustic sufficiently powerful to destroy them.”

Dehorning cattle, F. W. RANE and H. H. LAMSON (*New Hampshire Sta. Bul. 50, pp. 21-29, figs. 3*).—The bulletin consists of two articles: (1) Experience with the college herd, by F. W. Rane; and (2) preventing the growth of horns, by H. H. Lamson. A number of animals at the station were successfully dehorned. They regained their original vigor in a short time and the disposition of the herd was changed for the better. Concise directions for dehorning cattle are given. Preventing the growth of horns in calves by the use of caustic potash is described with considerable detail and the results of this method of treatment at the station are noted.

Veterinary department, J. H. WORST (*North Dakota Sta. Rpt. 1897, pp. 17-21*).—The report discusses experiments in the introduction of mallein, the effect of tuberculin upon the milk supply, blackleg, and the selection of cows for experimental purposes. In the author's opinion his experiments show forcibly that a reaction above 104° F. indicates the presence of glanders, a conclusion verified by *post-mortem* examinations. In the case of cows treated with tuberculin the milk yield was diminished 7.7 per cent; where they were not so treated it was diminished 11.4 per cent. Injected animals showed a loss of 7.9 of the total amount of butter fat, while those that were not injected showed a loss of 8.7 per cent.

The author states that experiments with blackleg have demonstrated that the disease can be eradicated by the employment of blackleg vaccine.

Bovine tuberculosis, P. FISCHER (*Kansas Sta. Bul. 79, pp. 81-109, figs. 5, dym. 8*).—This is an extended discussion of bovine tuberculosis, its cause, symptoms, and treatment. The application of the tuberculin test to the college herd is reported in considerable detail.

Hog cholera and swine plague, W. E. A. WYMAN (*South Carolina Sta. Bul.* 31, pp. 8).—This is a popular summary of the subject, describing hog cholera and swine plague, with remedies and methods of prevention.

Anthrax: A study of national and of State legislation on this subject, A. T. NEALE (*Delaware Sta. Bul.* 37, pp. 15).—This contains the enactments of Congress relative to anthrax and a discussion of the State legislation on the subject now in force in Delaware.

Blackleg: Its nature, cause, and prevention, V. A. NÖRGAARD (*U. S. Dept. Agr., Bureau of Animal Industry Circ.* 23, pp. 12, figs. 2).—This is a popular bulletin giving information as to the nature, symptoms, and treatment of the disease. The method of operating and the process of vaccination, care of utensils, and what animals should be vaccinated and the dose are brought out.

Second Annual Report of the State Veterinarian, E. P. NILES (*Virginia State Veterinarian Rpt.* 1897, pp. 15).—The bulletin includes the regulations concerning transportation of cattle in Virginia and the rules and regulations of the board of control of the agricultural experiment station for the extermination of contagious and communicable diseases among domestic animals. A proclamation of the Governor is quoted authorizing the establishment of live-stock quarantine lines, rules and regulations, and prescribing penalties for violating the same.

TECHNOLOGY.

Cane sugar and the process of its manufacture in Java, H. C. PRINSEN-GEERLIGS (*Manchester: J. Roberts & Sons*, 1898, pp. VI + 79 + V, fig. 1).

Wine making in Russia. III. Eastern Transcaucasus, M. BALLAS (*St. Petersburg: Department of Agriculture*, 1897, pp. XV + 403; *abs. in Selsk. Khoz.*, i *Lyesor.*, 189 (1898), Apr., p. 249).—Historical and statistical sketch.

The preparation of flax in its relation to flax culture, I. ELTRICH (*Die Flachsercütung in ihrer Beziehung zur Flachsbaufrage. Trautenau: I. Eltrich*, 1898).—A comparison of the different methods of preparing flax, with a special consideration of the expense incurred and the results obtained.

The manufacture of perfumes at Grasse, J. ROUCHE (*Jour. Hyg.*, 23 (1898), No. 1150, pp. 469-473).—This article is condensed from a study of the subject by H. de Parville in *La Nature*.

AGRICULTURAL ENGINEERING.

State aid to road building in Minnesota, A. B. CHOATE (*U. S. Dept. Agr., Office of Road Inquiry Circ.* 31, pp. 12, figs. 5).—This circular points out the injustice of the present system of "taxing farm property to improve all country roads, and city property to improve only city roads," and discusses a scheme of road legislation, the essential features of which are embodied in a proposed amendment to the State constitution, by which—

"The legislature is authorized to establish a State road and bridge fund and provide for a State highway commission, whose members must serve without compensation, and which shall have general supervision of the expenditure of the State road and bridge fund. This amendment does not contemplate that the State shall actually construct any wagon roads, but that it shall contribute not to exceed one-

third of the cost of any road, the other two-thirds to be paid by the locality where the road is built. The actual construction of the road so built is to be under the immediate supervision of the local authorities, the State commission simply determining, in a general way, what the character of the road shall be, and requiring, before the State pays any money for the improvement, that the road shall be constructed according to plans which it has approved."

Historical review of the work preparatory to the outlining of a general law for the purposes of draining and irrigating land (*Selsk. Khoz. i Lyceor., 186 (1897), Sept., pp. 481-554*).

Cultivation under artesian irrigation, C. H. GORMAN (*Agr. Gaz. New South Wales, 9 (1898), pt. 5, pp. 535-537*).—A discussion of artesian irrigation and its possibilities.

Hydrotechnical works and agricultural investigations in the region of the Siberian railway (*Selsk. Khoz. i Lyceor., 184 (1897), Mar., pp. 481-502*).

Report of the provincial instructor in road making, Ontario, 1897, A. W. CAMPBELL (*Ontario Dept. Agr., Rpt. Provisional Instructor in Road Making 1897, pp. 71, pls. 8, figs. 10*).—This report contains articles on good roads—a national problem, country roads, and the good roads movement: municipal and county reports on roads and road making; report of the Brantford board of trade on the streets of that city; report on the streets of Guelph, Ontario; extracts from a report on streets to the city of St. John, New Brunswick; and notes on the frontage-tax system.

STATISTICS—MISCELLANEOUS.

Tenth Annual Report of Mississippi Station, 1897 (*Mississippi Sta. Rpt. 1897, pp. 23*).—Brief reports by the director and heads of departments, including the report of the chemist, noted on page 315, and a financial statement for the fiscal year ending June 30, 1897. Some results secured in the irrigation of strawberries and vegetables are briefly recorded in the report of the horticulturist.

Reports of director and treasurer of North Dakota Station, 1897 (*North Dakota Sta. Rpt. 1897, pp. 3-8, 82, 83*).—Brief report on the work of the year and a financial statement for the fiscal year ending June 30, 1897.

The world's markets for American products—Norway and Sweden (*U. S. Dept. Agr., Section of Foreign Markets Bul. ^, pp. 68, map 1: 8, pp. 92, map 1*).—Revised editions (E. S. R., 8, pp. 175, 637).

Crop circulars for July, August, and September, 1898, J. HYDE (*U. S. Dept. Agr., Division of Statistics Crop Circs. July, Aug., and Sept., pp. 4 each*).—These contain the usual data relative to conditions of farm and orchard crops during these months, with summarized temperature and rainfall records for the same periods, and a discussion of the foreign crop situation in the July and August reports.

Experiment Station Work—V (*U. S. Dept. Agr., Farmers' Bul. 78, pp. 31, figs. 2*).—The following popular articles appear in this number of the Office of Experiment Stations series of Farmers' Bulletins: Humus in soils; swamp, marsh, or muck soils; rape; velvet bean; sunflowers; winter protection of peach trees; subwatering in greenhouses; bacterial diseases of plants; and grape juice and sweet cider.

Experiment Station Work—VI (*U. S. Dept. Agr., Farmers' Bul. 79, pp. 28, figs. 2*).—The sixth bulletin of this popular series prepared in the Office of Experiment Stations. The following subjects are treated: Fraud in fertilizers, sugar-beet industry, seeding grass land, grafting apple trees, forest fires, American clover seed, mushrooms as food, pigs in stubble fields, ensiling potatoes, and anthrax.

Accessions to the Department library, April-June, 1898 (*U. S. Dept. Agr., Library Bul. 23, pp. 25*).

The Department of Agriculture and its work, G. W. HILL (*U. S. Dept. Agr., Division of Publications, Doc. 278, pp. 11, figs. 2*).—Brief notes on the organization of
8192—No. 4—8

the bureaus, offices, and divisions of this Department, with a diagram of the Department grounds in Washington, D. C.

Report of education committee on the results of the examination in agriculture, 1898 (*Jour. Roy. Agr. Soc. England, 3. ser., 9 (1898), pt. II, No. 34, pp. 377-387*).—An examination for the diploma in the science and practice of agriculture given by the Royal Agricultural Society of England. The subjects of the examination were agriculture, chemistry, bookkeeping, mensuration and land surveying, agricultural engineering, botany, geology, veterinary science, and agricultural entomology. The questions for each subject are given.

Agricultural monograph of the Department of Drôme, BRÉHERET (*Bul. Min. Agr. [France], 17 (1898), No. 4, pp. 811-867*).—This monograph discusses soil and climate, crops, animals, fertilizers and soil amendments, tillage, agricultural and associated industries, land improvements, rural economy, and encouragement to agriculture and agricultural education.

Agricultural monograph of the Department of Gironde, F. VASSILLIÈRE (*Bul. Min. Agr. [France], 17 (1898), No. 1, pp. 73-144*).—Discusses soil and climate, crops, animals, fertilizers and soil amendments, tillage, agricultural and associated industries, land improvements, rural economy, and encouragement to agriculture and agricultural education.

Tea districts of the subtropical regions of Asia, A. N. KRASNOV (*Pt. 1, Japan. St. Petersburg, 1897, pp. XXII+244, figs. 101, maps 2. Pt. 2, China, India, Ceylon, and Colchis. St. Petersburg, 1898, pp. 247+618, figs. 97. Rev. in Selsk. Khoz. i Lyesor., 189 (1898), May, p. 470*).

Proceedings of the fourth meeting of the Agricultural Council (*Selsk. Khoz. i Lyesor., 189 (1898), June, pp. 481+576; 190 (1898), July, pp. 1-88*).—Chiefly devoted to the elaborating of general statutes for agricultural schools.—P. FIREMAN.

The foundations of scientific agriculture, S. COOKE (*London, New York, and Bombay: Longmans, Green & Co., 1897, pp. 268, pl. 1, figs. 85*).—This is a text-book intended for use in the provincial schools and colleges of India, the larger part of which was originally prepared in the form of lectures for use in the instruction of students of agriculture, engineering, and forestry at the Poona College of Science. The subjects treated are air and water; sunshine, rain, and climate; rock-forming minerals; soil-forming rocks; soil-forming agencies; varieties, classification, composition, and analyses of soil; relation of plant food to the atmosphere and the soil—plant growth and architecture; nature and varieties of crops; manures for the soil and crops; the cultivator and his art; and measurements, etc. A glossary of terms and a series of examination questions are given, as well as appendixes containing a list of the stratified rocks of the British Isles, with their economic contents; an account of an experiment with manures prepared from street sweepings; and a discussion of the educational uses of famme.

The work is adapted especially to the needs of the Indian agriculturist, the illustrations of principles being drawn from the climatic soil, crop, and social and economic conditions which obtain in India.

A chapter of especial interest is that devoted to the characteristics and culture of Indian crops.

NOTES.

MARYLAND STATION.—C. O. Garner has been elected assistant agriculturist to succeed E. H. Brinkley, and C. F. Doane, a graduate of Kansas Agricultural College and post-graduate of Wisconsin University Dairy Department, has been appointed assistant in dairying and dairy bacteriology. A new office building and greenhouses for the horticultural department have recently been constructed.

MASSACHUSETTS HATCH STATION.—A small dairy building, to cost about \$2,000, is being constructed for the station at State expense. It will be used for experimental purposes, and especially for studying the effect of different feed stuffs upon the quality (flavor, hardness, etc.) of butter. It is hoped later to take up investigations in dairy bacteriology. The building is of wood, all the outside walls having dead-air spaces, and is 44 ft. long and 21 ft. wide, with an office jutting out from the building 8 by 10 ft. The main building contains an ice house 14 by 20 ft., located at the north end. The general dairy room, situated in the center of the building, is 16 by 20 ft.; the pasteurizing and cream-ripening rooms at the south end are each 10 by 12 ft. The general dairy room will contain the milk-receiving vat, separator, churn, and butter worker. The pasteurizer and receiving vat are $3\frac{1}{2}$ ft. above the separator, so that the milk will be carried to the latter by gravity. The floor of the building will be of artificial stone and the walls of adamant plaster, covered with several coatings of enamel paint. Steam will be supplied from a boiler located in the basement of the experiment barn 100 ft. distant. The power for running the separator, churn, and butter worker will be supplied by a water motor, thus doing away with an engine and keeping coal dust, etc., entirely out of the creamery.

NEW HAMPSHIRE COLLEGE AND STATION.—The department of agriculture and horticulture has been divided into two departments. The department of horticulture will include the garden, greenhouses, and grounds around the experiment-station building, and will be in charge of F. M. Rane, horticulturist. The department of agriculture will include the farm, barns, and live stock, and will be in charge of Charles W. Burkett, associate professor of agriculture and agriculturist.

NORTH CAROLINA STATION.—This station, upon the recommendation of the director and horticulturist, and by order of the board of trustees, has withdrawn from the management of the experimental farm of the North Carolina State Horticultural Society, located at Southern Pines, North Carolina.

OKLAHOMA STATION.—The board of regents has been reorganized as follows: President, B. S. Barnes, Ponca City; treasurer, C. J. Benson, Shawnee; C. M. Barnes, (*ex-officio*) Guthrie; R. J. Edwards, Oklahoma City; J. C. Tousley, El Reno; and F. J. Wikoff, Stillwater.

VIRGINIA STATION.—Charles McCulloch, a graduate of the American Veterinary College and of the Columbian University, has been appointed assistant veterinarian, *vice* F. S. Roop, resigned.

WASHINGTON STATION.—S. B. Nelson, veterinarian of the station, has been made secretary to the State Board of Health.

WYOMING STATION.—This station has made a change in the system of its publications. Hereafter the bulletins will be popular accounts of the work of the station and adapted to local needs, while all matters of a technical nature will be published in the annual report. Bulletins will not be sent outside of the State except on request, but the annual reports, including the bulletins, will be sent to the official list.

AGRICULTURE OF THE PHILIPPINES.—Lieut. A. P. Hayne, formerly of the California University and Station and at present stationed in Manila, has been detailed at

the request of the Secretary of Agriculture to investigate the agriculture of the Philippine Islands. He will be in charge of an expedition to make an agricultural survey of the islands, and will be assisted in this work by a detail of about 50 men now serving in the Volunteer Army, most of them college graduates and several graduates of our agricultural colleges.

NECROLOGY.—Dr. Ferdinand Cohn died suddenly at Breslau June 25 of heart disease. He was born in 1824 and has occupied the chair of botany at Breslau since 1859. During recent years he has been engaged principally in the field of bacteriology and has written a book on the Development of Microscopic Algae and Fungi, showing the destructive action of parasitic forms. Dr. Brefeld, of Münster, has been elected his successor.

Professor Gibelli, professor of botany and director of the botanic garden at Turin, died September 16, 1898.

Dr. Anton Ritter Kerner von Marilaub, director and professor of botany of the botanical gardens at Vienna, died June 21, 1898.

Prof. Ernst Stöckhardt, formerly director of the Agricultural Institute at Jena, died at Bautzen on March 27, 1898.

MISCELLANEOUS.—Notice is given by the Royal Academy of Economy and Agriculture of Florence that a meeting will be held at that place during 1899 to consider the subject of the advanced or delayed maturity in certain plants under varying conditions, the principal subjects of consideration being the difference in the growth of woody and herbaceous plants when removed to latitudes or altitudes different from those of their original habitat. The society has concluded to offer a prize of 1,200 francs and a diploma and silver medal for the best monograph on the subject proposed. The papers must be written in Italian or French and submitted to the academy by June 30, 1900. The secretary of the academy is A. Franchetti.

A division of agriculture and forestry has been established in connection with the German Imperial Health Office at Berlin. The new division will be in charge of Prof. Georg Röhrig, of Königsberg. Prof. Moritz, formerly of the chemical division of the Health Office, has accepted a position. Prof. J. Behrens, of Karlsruhe, has been appointed agricultural bacteriologist, and Dr. C. Freiherr von Tübenf, formerly director of the Bavarian station of plant protection and plant diseases, will become the botanist.

A department of agronomy is to be added to the Bohemian technical high school at Prague, and Dr. J. Stokiasa has been selected as professor of plant production.

The University of Aberdeen, Scotland, has received a bequest of \$60,000 for the establishment of a garden under the name of the Cruekshank Botanical Garden, and Prof. James W. Traud has been appointed to the directorship of the same.

Dr. Charles R. Barnes, of the University of Wisconsin, has gone to Chicago University as professor of plant physiology. He has been succeeded in the University of Wisconsin by Dr. R. A. Harper, late of Lake Forest University.

Dr. Arthur Bornträger has been chosen as director of the agricultural station at Palermo, Sicily.

Dr. Buchner, of Tübingen, has become professor in the agricultural high school of Berlin.

Dr. F. W. Dafert has been appointed director of the Imperial Agricultural Chemical Experiment Station in Vienna.

Dr. A. G. Grevillius has removed from Münster to the agricultural experiment station at Kempen on the Rhine.

Dr. Daniel Morris has been appointed commissioner of the Imperial Department of Agriculture for the West Indies. Dr. Morris was formerly assistant director of the Royal Gardens at Kew.

Dr. A. Richter has been chosen chief of the botanical division of the Hungarian National Museum.

Dr. Hugo Zukal has been made extraordinary professor of phytopathology in the High School for Soil Culture in Vienna.

CONTENTS OF Vol. X, No. 5.

	Page.
Biological and dairy building of New York State Experiment Station	401
Recent work in agricultural science	407
Notes.....	499

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

Formation of furfural from cellulose and its oxy and hydro derivatives, L. Vignon	407
The reduction of nitric oxid by copper, with special reference to Dumas's method of estimating nitrogen, T. Gray	408
On the determination of potash without the previous removal of iron, calcium, etc., C. C. Moore	408
Determination of potash in potassic fertilizers, L. Ronnet.....	409
Method of preparing a strictly neutral ammonium citrate solution, A. D. Cook	410
A method for determining perchlorate in sodium and potassium nitrates, N. Blattner and J. Brassens	410
The determination of phosphoric acid in superphosphates, L. Vignon	410
A new method for determining crude fiber in foods and feeding stuffs, J. König.....	411
Decomposition of monobarium and monocalcium phosphates by water at 100° C., G. Viard.....	411

BOTANY.

	Page.
On the nitrogen assimilation of plants, L. Lutz	414
Influence of diffused light on the development of plants, J. Wiesner	414
On the direct fertilization of plants whose flowers seem adapted to cross fertilization, C. Gerber	415
Penicillium as a wood-destroying fungus, H. Marshall Ward	415
Two useful grasses	415
West Australian grasses, F. Turner	416

METEOROLOGY.

Monthly Weather Review, Vol. XXVI, Nos. 7-9	418
Moisture tables, C. F. Marvin	419
Department of meteorology and agricultural engineering, 1896-97, C. H. Pettee	419
Meteorological observations	419

AIR—WATER—SOILS.

Salt River Valley soils, R. H. Forbes	420
Materials for the study of Russian soils, XI, A. Soyvetov and N. Adamov	421
Composition of Indian soils, J. W. Leather	421
The judging of the physical properties of soils by means of the heat which they evolve when moistened, A. Mitscherlich	423
Moisture investigations for 1897, E. C. Chulcott and A. B. Hohn	424

FERTILIZERS.

Experiments with lime on acid soils, F. S. Earle and A. W. Orr	425
On the influence of crops and manure on the nitrogen content of soils, C. F. A. Tuxen	425
On the production of barnyard manure, P. Gay and Dupont	426
Fertilizers	426
Analyses of commercial fertilizers, B. W. Kilgore et al.	428
Analyses of fertilizers, C. A. Goessmann	428
Analyses of fertilizers, C. A. Goessmann	428

FIELD CROPS.

The effect of certain methods of soil treatment upon the corn crop, T. L. Lyon	428
Preservation of corn stover, D. O. Nourse	429
An experiment with clover, F. W. Rane	429
A preliminary report on the experiments with forage crops, T. L. Lyon	429
On the change of the composition of green fodders at different periods of vegetation, P. Azaryevich	430
Cooperative fertilizer experiments with cotton in 1897, J. F. Duggar	431
Seeding grass without grain, C. B. Lane	431
Commercial fertilizers for potatoes, W. H. Jordan	431
Comparison of varieties of potatoes, F. W. Rane	432
Irrigation	433

HORTICULTURE.

Report of the assistant in horticulture, A. T. Jordan	433
Experiments in shading, B. D. Halsted	435
Variety tests of fruits, S. T. Maynard	436
Hardy apples for cold climates, F. A. Waugh	437
Some results following the application of wood ashes in the apple orchard, S. A. Beach	437

EXPERIMENT STATION RECORD.

VOL. X.

No. 5.

The New York State Experiment Station at Geneva has recently completed and dedicated a biological and dairy building (fig. 10) which contains many features of interest and some which are unique.

An appropriation of \$41,000 was made by the State assembly in 1896 for the construction and equipment of a building to be devoted to the biological sciences and to dairying. Steps were immediately taken to secure plans and let contracts, but it was not until September, 1897,

FIG. 10.—Biological and Dairy Building, New York State Experiment Station.

that ground was broken for the foundation, and about a year was required for completing the building.

The new laboratory consists of a main building, 88 by 38 feet, and 2 wings, 33 ft. wide and extending 30 ft. to the rear, giving an open court 16 ft. in width between the wings. It is 2 stories in height, with a basement extending under the entire building. The building material of both the main building and wings is the best quality of cream-

colored pressed brick, with Medina stone trimming. The basement is 11 ft. clear, the concrete floor being at grade in the rear, with doors into each wing and into the main building from the court. There are 2 elevators for the delivery of supplies and the handling of the dairy products, one in front to the first story, and one in the rear to both first and second stories. The roof is of slate, with galvanized iron cornices, and is so shaped that the attic rooms are large and high. Abundance of light is given these rooms through 6 double dormer windows at the sides, a round window in front, and a skylight above.

The interior of the building is finished in quartered oak; hard plaster is used throughout; and the floors are of Southern pine except in the vaults and 4 dairy rooms, where vitrified tile is used.

FIG. 11.—Basement plan of Biological and Dairy Building, New York State Experiment Station.

The building is heated by steam from two 30 horsepower boilers, the radiators in each room being controlled by automatic valves connected with thermostats and operated by compressed air by the Johnson system. Steam from the boilers, compressed air and hot water from the compressor and heater (both also in the basement), and cold water and gas from the city system are supplied at the laboratory tables and other convenient points. Constant pressure upon the water system is maintained by connection with a 1,000-gallon tank in the attic.

For securing constant temperatures in the cheese-curing rooms and bacteriological culture rooms, and low temperature in the dairy and cold-storage rooms, a supply of cold air is necessary. This is furnished by an extensive refrigerating plant, operating on the ammonia-expansion principle, located in the basement. Expansion coils connected with the apparatus are provided in a cheese room in the basement, the butter room, pasteurizing room, cold-storage room, and large insulated rooms in the attic. Part of these coils are immersed in brine tanks, so that a low temperature, secured during the day, can be maintained at

FIG. 12.—First floor plan of Biological and Dairy Building, New York State Experiment Station.

night without running the machinery. The power for the compressor and other machinery is furnished by a 25-horsepower horizontal engine.

The building is well supplied with wash basins, sinks, and closets, the most modern and thoroughly sanitary plumbing and drainage being used throughout.

In the basement (fig. 11) are the machinery and boiler rooms, several large coal and storage rooms, and one large room for curing Brie, cream, and similar cheeses which require moisture and darkness. This room is provided with cooling apparatus.

On the first floor (fig. 12) the 5 rooms occupying the left side of the main building and the east wing are devoted to horticulture. These consist of a horticulturist's office, 18 by 15 ft., with a large dark closet attached; horticulturist's laboratory, 20 by 14 ft.; assistant horticulturists' office, 20 by 17½ ft.; assistants' laboratory, 32 by 14⅓ ft., and a museum, 32 by 14⅓ ft. One of the fireproof vaults for the preservation of records is located in this part of the building, the other vault being upon the second floor, just above it. The museums also are practically fireproof. The offices here, as throughout the building, are thoroughly equipped with oak furniture. The laboratories each have a large work table, with Alberene stone top and sink, fitted with the conveniences previously mentioned. The windows are provided with wide microscope tables or shelves; and these as well as the projecting ledges of the microscope and reagent cases are fitted with removable plate-glass tops to prevent staining.

At the right of the main entrance is the office of the dairy expert, which opens into another hall at right angles to the main one and leads to the butter room. The latter is 32 by 20 ft. in size and, like the milk-receiving room, pasteurizing room and cheese room, is finished entirely in white. The floors of these rooms are of vitrified tile, with sufficient pitch to give ready drainage, and the sides have a wainscoting of enameled brick. The apparatus is also all finished in white enamel. In the south end of the butter room, next to the milk-receiving room, are the four separators—a United States steam turbine, a United States belt power with intermediate connection, a DeLaval steam turbine, and an Empire with direct belt connection. Near the middle of the room is the box churn, which contains four compartments so that four samples of cream may be handled at once under uniform conditions. At the north end of the room are the hand and power butter workers, with expansion coils above to secure proper temperature. This portion of the room can be shut off from the rest by a curtain when necessary. Opening from this room are an elevator to the basement, a large closet, and the cold storage room. The milk-receiving room has an outer door leading to a platform, and contains a large vat and steam pump to receive the milk and distribute it to separators, pasteurizer, or cheese vats.

In the pasteurizing room are the steam pasteurizer, milk cooler, and Babcock tester. The upper coils over which the milk flows in the cooler circulate cold water and the lower ones ammonia, so that economical and rapid cooling is secured. The cheese room communicates by an elevator with the basement and with the second story near the cheese-curing rooms, and contains one large and two small cheese vats, and large and small constant pressure cheese presses.

Upon the second floor (fig. 13) the arrangement of rooms in the left half does not differ from that of the first story. These rooms are the botanist's office, laboratory, and museum, and the entomologist's office and laboratory. The cheese curing rooms occupy the right wing, and are

separated from its outer wall on all sides by a 4-foot passageway. They are further insulated by double walls and air spaces on the outside and between the separate rooms. These rooms are 6 in number, each 9 by 10 ft., with shelves 14 in. wide and 12 in. apart over the entire wall space. It is expected to control the temperature in each of these rooms within 2° , running each room independently and at any temperature between 30 and 90° . A hot-air flue from below, and a cold-air flue from the chamber in the attic containing the expansion coils and brine tanks, lead into each room. These flues are closed by dampers operated by compressed air and controlled by thermostats. When the temperature

FIG. 13.—Second floor plan of Biological and Dairy Building, New York State Experiment Station.

falls 1° below the point fixed upon, the thermostat turns a valve and the compressed air opens the hot-air damper near the floor. Should the temperature rise, the cold-air flue in the ceiling is opened. So delicate is the operation of this system that breathing upon the thermostat will open the cold-air flue, and fanning it will open the hot-air damper.

In front of the second story and to the right of the center are the bacteriologist's office and laboratory, a culture and incubator room, and a storage and work room. A portion of the incubator and culture room can be shut off from the rest by a glass partition and its temperature

held where desired by a cold-air flue and radiator automatically controlled.

In the attic only the east half has been finished off and these rooms are used for photographic work. These consist of a gallery 36 by 34 ft., lighted by an 8 by 10 ft. skylight and a large double dormer window, a dark room, and a finishing room.

In the west half of the attic is the chamber containing the large ammonia expansion coils and brine tanks. This chamber is insulated with great care by air spaces on all sides and by thick double-air-spaced walls, so that very little heat from without can enter.

It will be seen that the facilities offered by this new building are exceptional for the study of dairy problems, and especially those connected with cheese making. The details of the process of curing cheese are very imperfectly understood at the present time, even by scientists, who differ in their theories as to the nature and cause of the changes which take place and the conditions which influence them. The subject is an intensely practical one, and the more so from the fact that in practice the curing process receives relatively little attention from cheese makers. "The watchful eye of the maker is too often diverted from the cheese as soon as it is placed upon the shelves. An inspection of the conditions under which cheese is cured in this country almost without exception shows that the details of the curing process receive little or no attention. Curing rooms are built in the cheapest possible manner. No attempt is made to control the temperature or the moisture content of the same. It is not at all uncommon to find cheese stored in places the temperature of which is subject to almost as much fluctuation as the outside air."¹

This is possibly too strong a statement as applied to the whole country, but it undoubtedly represents a condition of affairs which prevails in a large majority of cheese-making establishments, resulting in a "monetary loss amounting to many millions of dollars."

The arrangements in the new building for controlling the temperature of the cheese-curing rooms, with additional arrangements to be provided for controlling the humidity, will afford exceptional means for studying this phase of the ripening process. The services of a bacteriologist, who entered upon his duties with the beginning of the new year, will be an additional element of strength.

It is a matter for congratulation that the important investigations in cheese making which the station has made in the past are to be resumed under such favorable conditions.

¹ Babcock and Russell.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Formation of furfural from cellulose and its oxy and hydro derivatives, L. VIGNON (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 19, pp. 1355-1358).—In these investigations cotton fiber was subjected during 1 hour at a boiling temperature to the action of (1) hydrochloric acid, (2) potassium chlorate, and (3) stannous chlorid. In the first and third cases hydrocelluloses were obtained; in the second case an oxycellulose was formed. These three substances, as well as starch and cotton fiber bleached with chlorin and oxycellulose obtained from such fiber by treatment with chromic acid, were subjected to the action of hydrochloric acid (1.06 sp. gr.) at a boiling temperature according to the Tollens method for the determination of furfural. The furfural was determined in the distillate from the solutions by means of phenylhydrazin. The results are given as follows:

Furfural obtained from cellulose, cellulose derivatives, etc.

	Furfural.		Furfural.
	<i>Per cent.</i>		<i>Per cent.</i>
Hydrocellulose (1).....	0.854	Starch	0.800
Oxycellulose (2).....	2.113	Bleached cotton	1.800
Reduced cellulose (3).....	.860	Cotton fiber treated with chromic acid.	3.500

During the formation of the furfural carbon dioxide was evolved, which was collected and determined. The carbon dioxide evolved bore a fixed relation to the amount of furfural obtained.

The author also studied the formation of furfural from the products of decomposition of oxycellulose by potash. Samples of oxycellulose prepared by treating cotton fiber with chlorate of potash and hydrochloric acid (A) and with chromate of potash and sulphuric acid (B) were treated with potassium hydrate (20° Baumé) at ordinary temperature for 5 hours, using 200 cc. of the potash solution to 25 gm. of the oxycellulose. In each case an insoluble residue remained. By saturating the potash solution with hydrochloric acid, a white gelatinous precipitate was obtained which was collected and dried. A certain

amount of material remained dissolved in the potash solution after neutralization. These 3 products were tested for furfural with the following results:

Furfural in potash decomposition products of cellulose derivatives.

	Furfural.	
	A.	B.
	<i>Per cent.</i>	<i>Per cent.</i>
Insoluble residue.....	0.86	0.76
Precipitate from potash solution.....	4.35	5.11
Substance not precipitated by acid.....	1.10	1.54

The reduction of nitric oxid by copper, with special reference to Dumas's method of estimating nitrogen, T. GRAY (*Jour. Soc. Chem. Ind., 17 (1898), No. 8, pp. 741-743*).—In order to determine the conditions in the Dumas method of determining nitrogen under which reduction of nitric oxid by metallic copper takes place, the author passed pure nitric oxid and mixtures of the oxid with nitrogen, at different rates, over copper spirals of different lengths heated to redness in combustion tubes, and analyzed the resulting gas. The results showed that when the copper was sufficiently heated, it was a very efficient reducing agent. Spirals which had been oxidized and reduced several times proved to be more effective than new spirals.

“A 3-in. spiral effected complete reduction of the nitric oxid when the mixed gases were passed over it at such a rate that approximately 30 cc. were collected in about 3 minutes, but part of the nitric oxid escaped reduction when the speed was increased much above this. With a 5-in. spiral complete reduction took place even when the rate of passage was about three times as great. This rate is very much greater than that at which a combustion is conducted, but the conditions are not identical, as the gases in the latter case are diluted to a considerable extent by the carbon dioxide and water vapor produced by the oxidation of the carbon and hydrogen of the substance.”

To determine the efficiency of reduction under the conditions of ordinary combustion, examinations were made of the gas obtained by combustion with a 5-in. spiral of acetanilid, uric acid, and hippuric acid. The gas was free from nitric oxid in all but 2 cases, and in these the amounts were very small.

The author concluded that when carbon dioxide is used to expel the air from the combustion tube, “a spiral 5 in. long should be used. This should be tightly rolled and of such a thickness that some pressure is necessary to push it into the combustion tube. The spiral should be strongly heated and the current of carbon dioxide which is used to expel the air from the tube should be stopped while the combustion is taking place.”

On the determination of potash without the previous removal of iron, calcium, etc., C. C. MOORE (*Jour. Amer. Chem. Soc., 20 (1898), No. 5, pp. 340-343*).—The acid solution of the substance, without previous removal of calcium, iron, etc., is evaporated on a steam bath

with slight excess of platinum chlorid until the residue solidifies on cooling. From 15 to 25 cc. of acidulated alcohol prepared by passing dry hydrochloric-acid gas into cool 90 per cent alcohol is then added to the solution, which is allowed to stand 2 or 3 minutes, with occasional stirring. The solution is passed through a filter and the residue washed once or twice by decantation, then thrown upon the filter and washed with the acid alcohol until the excess of platinum chlorid is removed. The precipitate is then washed first with ammonium chlorid solution (200 gm. of chlorid per liter of water) and afterwards with 85 per cent alcohol.

The acidulated alcohol used in this method is prepared by gently heating strong aqueous hydrochloric acid in a flask and passing the liberated gas through sulphuric acid and into alcohol kept in a cooled vessel. This is continued until 1 cc. of the alcohol neutralizes about $\frac{2}{3}$ cc. of normal potassium hydroxid.

The method was tested with very satisfactory results on a sample of ash and on mixtures of known composition containing varying amounts of potassium, calcium, sodium, iron, and aluminum salts. In case ammonium salts are present, it is recommended that they be decomposed and removed by means of nitric acid, as explained in Croke's Select Methods, p. 32.

Determination of potash in potassic fertilizers, L. RONNET (*Rev. Chim. Analyt.*, 1897, No. 21; *abs. in Bul. Assoc. Chim. Sucr. et Distill.*, 16 (1898), No. 1, pp. 76, 77).—The author recommends the following modification of Schloesing's method: In case of potassium chlorid dissolve 50 gm. of material in water, make up to 1 liter, mix, and filter. To 20 cc. of the filtrate add 10 cc. of saturated solution of barium hydrate; pass carbon dioxid through the solution for a few minutes to precipitate the excess of barium, and boil on a water bath until the carbon dioxid dissolved in the solution and contained in bicarbonates is driven off; filter, add perchloric acid, and continue the operation in the usual way.

Potash is determined in sulphate and kainit in exactly the same manner, except that 40 cc. of the barium solution is used in case of the sulphate and 30 cc. in case of the kainit and the precipitate is washed longer.

In the case of complex fertilizers dissolve 25 gm. in hot water. After cooling, make up the volume to 500 cc., mix, and filter. Evaporate 100 or 200 cc. of this filtrate to dryness in the presence of 1 or 2 gm. of slacked lime. Calcine at a low temperature until the organic matter is destroyed, the ammonia salts volatilized, and superphosphates transformed into insoluble tribasic phosphates. Take up in a small quantity of boiling water, filter, add barium solution as long as any precipitate forms, precipitate excess of barium with a current of carbon dioxid, boil, and filter. Determine potash in the filtrate in the manner described above.

Method of preparing a strictly neutral ammonium citrate solution, A. D. COOK (*Jour. Amer. Chem. Soc.*, 20 (1898), No. 8, pp. 585, 586).—The difficulty of preparing a strictly neutral ammonium citrate is briefly discussed and the following method is recommended:

“Seven hundred and forty grams of commercial citric acid is carefully weighed out and placed in a 4-liter graduate containing 1,900 cc. of 10 per cent ammonium hydroxid. With a suitable glass rod the citric acid is thoroughly and vigorously stirred until the citric acid has all dissolved. Distilled water is now added until the meniscus reads 1,000 cc. The solution is again stirred and carefully transferred to a large porcelain evaporating dish. The solution is allowed to stand over night and in the morning large oval crystals are noticeable on the sides of the 4-liter graduate, and invariably the solution when tested for neutrality will be found strictly neutral. If the solution is not vigorously stirred sufficient heat will not be evolved to drive off the excess of ammonia, and when tested will be found to be slightly alkaline, but by resorting to vigorous stirring a strictly neutral reaction will be obtained. The solution, after being transferred to the reagent bottle, is brought to the required temperature, 20° C., and distilled water added until the specific gravity is 1.09. On testing the neutrality of this solution, both with coralline and cochineal as indicators, it will be found unnecessary to alter its neutrality in the least degree, the solution being strictly neutral.”¹

A method for determining perchlorate in sodium and potassium nitrates, N. BLATTNER and J. BRASSEUR (*Bul. Soc. Chim. Paris*, 3. ser., 19 (1898), No. 12, p. 539; and *Chem. Ztg.*, 22 (1898), No. 59, pp. 589, 590).—The method recommended is as follows: Determine chlorine by the usual method in the original substance, then dry and pulverize 5 or 10 gm. of the nitrate. Mix with 8 to 15 gm. of pure lime obtained by calcining pure precipitated calcium carbonate. Place the mixture in a covered platinum or porcelain crucible and heat in the flame of a Bunsen burner for 15 minutes. After cooling remove the contents of the crucible to a flat-bottomed flask, dissolve in dilute nitric acid (free from chlorids), and determine chlorine in the solution by means of silver nitrate either in acid solution, according to Volhard, or in a solution neutralized by calcium carbonate, or by weighing the silver chlorid. By this means chlorine in chlorids, chlorates (if any are present), and perchlorates are determined. From these data the amount of perchlorates present may be calculated.

The determination of phosphoric acid in superphosphates, L. VIGNON (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 21, pp. 1522, 1523; 127 (1898); No. 3, p. 191).—The determination of water-soluble and citrate-soluble phosphoric acid in 1 sample of bone superphosphate and 2 samples of mineral superphosphate are reported. The percentages of soluble phosphoric acid found were 14.32, 14.13, and 10.20 per cent, respectively. The percentages of citrate-soluble phosphoric acid were 0.77, 0.27, and 3.1, respectively, when the solution was allowed to stand 8 hours before filtration and 1.08, 0.45, and 3.18, respectively, when allowed to stand 15 hours before filtration. When phosphoric

¹Compare De Roode's method, *Jour. Amer. Chem. Soc.*, 17 (1895), p. 47 (*E. S. R.*, 6, p. 864).

acid was determined in the combined water solution and citrate extract, the following percentages were found, viz. 17.79, 14.94, and 13.91. Subtracting the percentages of water-soluble phosphoric acid from these figures, we have for citrate-soluble phosphoric acid, by difference, 3.47, 0.81, and 3.71 per cent, figures which are much higher than those obtained by determining the citrate-soluble phosphoric acid separately. The author recommends the method of determining phosphoric acid in the combined solutions as more rapid and accurate than separate determinations, especially when, as is usual in superphosphates, the amount of citrate-soluble phosphoric acid is small.

A new method for determining crude fiber in foods and feeding stuffs, J. KÖNIG (*Ztschr. Untersuch. Nahr. u. Genussm.*, 1898, No. 1, p. 3; *abs. in Centbl. Agr. Chem.*, 27 (1898), No. 10, pp. 706-711).—The author calls attention to the fact that the treatment with 1.25 per cent sulphuric acid and potash solution by the Weende method for crude fiber only dissolves a part of the pentosans, and describes a method which he has worked out for the determination of crude fiber freed so far as possible from pentosans. The method is as follows: Three grams of air-dry substance is mixed in a porcelain dish of 500 cc. capacity with 200 cc. of glycerin containing 20 gm. of concentrated sulphuric acid to the liter. The glycerin used is of 1.23 sp. gr., i. e., contains 87.5 per cent of glycerin. The dish is placed in an autoclave and heated under three atmospheres pressure, i. e., 137° C., for 1 hour. After cooling to 80 to 100° the dish is removed, the contents diluted with 200 to 250 cc. of boiling water, and filtered hot on a porcelain filter plate covered with finely divided asbestos, or on a Gooch crucible. The residue is washed with boiling water, alcohol, and a mixture of alcohol and ether until the filtrate is colorless, after which it is dried to constant weight, incinerated, and weighed, the loss in weight on ignition being taken as ash-free crude fiber. With an autoclave 25 cm. deep and 25 cm. in diameter 4 determinations can be made simultaneously. In the absence of an autoclave the digestion may be carried on in a 600 cc. flask with a reflux condenser, heating at boiling for 1 hour. At a temperature of 120 to 130° frothing usually occurs, but as soon as the liquid comes to boiling there is no further danger of this. The method gives a crude fiber containing from 0 to 6.62 per cent of pentosans. It was found more difficult to remove the pentosans from leguminous coarse fodders than from grasses.

Decomposition of monobarium and monocalcium phosphates by water at 100° C., G. VIARD (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 3, pp. 178-180).—Joly and Sorel¹ have shown that monobasic phosphates of the alkaline earths partially decompose in cold water with the formation of dibasic phosphate, which is precipitated, and free phosphoric acid, which remains in solution with the undecomposed monobasic phosphate. The author's experiments show that the same

¹ *Compt. Rend. Acad. Sci. Paris*, 118 (1894), pp. 738-741.

decomposition occurs in water at 100° C., the limit being reached when the ratio of total phosphoric acid to combined phosphoric acid was 2.8 in case of monobarium phosphate and 2.34 in case of monocalcium phosphate. The precipitate formed was in every case anhydrous dibasic phosphate insoluble in acetic acid.

A new gas, C. F. BRUSH (*Science, n. ser., 8* (1898), No. 198, pp. 485-494, fig. 1; *Jour. Amer. Chem. Soc., 20* (1898), No. 1, pp. 899-911, fig. 1).—A paper read before the American Association for the Advancement of Science, August 23, 1898, announcing the discovery of a new constituent of the atmosphere to which the name "etherion" is given. "Its chief characteristic thus far ascertained is enormous heat conductivity at low pressures."

Classification of proteids, R. H. CHITTENDEN (*Centbl. Physiol., 11* (1898), p. 497; *abs. in Vrtljschr. Chem. Nahr. u. Genussmth., 12* (1898), No. 1, p. 495).—The author calls attention to the fact that in 1891 he published a classification similar to Wroblewski's (*E. S. R., 9*, p. 180).

Nitration of cellulose and of its hydro and oxy derivatives, L. VIGNON (*Compt. Rend. Acad. Sci. Paris, 126* (1898), No. 3, pp. 1658-1661).—This is a continuation of previous work (see p. 407), in the course of which it was shown that cellulose and hydrocellulose yielded small quantities of furfural and the nitro-oxycellulose large quantities.

On the determination of phosphoric acid, H. LASNE (*Compt. Rend. Acad. Sci. Paris, 127* (1898), No. 1, pp. 62-64).—The author reports determinations of water-soluble and citrate-soluble phosphoric acid in mineral, raw bone, and degelatinized bone superphosphate which show that small amounts of citrate-soluble phosphoric acid may be accurately determined by precipitation in the extract if the solution is allowed to stand 16 hours before filtration.

Formation of furfural from starch and its derivatives, F. SESTINI (*L'Orosi, 21*, pp. 109-113; *abs. in Jour. Soc. Chem. Ind., 17* (1898), No. 9, p. 861).—Starch heated dry at about 200° C. and in the presence of acids at 100° C. is said to yield furfural.

On the Lindo-Gladding method of determining potash, A. L. WINTON and H. J. WHEELER (*Jour. Amer. Chem. Soc., 20* (1898), No. 8, pp. 597-609).—This is a paper prepared by a committee appointed by the Association of Official Agricultural Chemists of the United States with a view to meeting certain criticisms of the Lindo-Gladding method of determining potash, notably those of Vogel and Haefcke (*E. S. R., 8*, p. 457).

Determination of sulphuric acid in wine and vinegar, F. BIMBI (*Bol. Chim. Farm., 37*, p. 133; *abs. in Bul. Soc. Chim. Paris, 3. ser., 20* (1898), No. 13, p. 575).

Remarks on wine and vinegar analysis, L. ERCKMANN (*Chem. Ztg.*, 22 (1898), No. 66, p. 673).

Sewage analysis and standards of purity for effluents, C. G. MOOR (*Analyst*, 23 (1898), Aug., pp. 198-209).

The Lamausky-Nobel viscosimeter, L. SINGER (*Chem. Rev. Fett u. Harz-Ind.*, 4, No. 18, pp. 243-246; *abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 2, pp. 182, 183).

Determination of water in milk, butter, etc., A. WRÓBLEWSKI (*Oesterr. Chem. Ztg.*, 1 (1898), No. 11, pp. 331, 332, fig. 1).—The method proposed is similar to the Adams method. Strips of paper are rolled and packed into a weighing glass. After drying to constant weight, the rolls are saturated with 10 to 20 cc. of milk, weighed and dried to constant weight; or in the case of butter, 5 to 10 gm. are placed in small pieces on the rolls, melted by gentle heat and then dried to constant weight.

Milk analyses II, M. WEIBULL (*K. Landt. Akad. Handl. Tidskr.*, 7 (1898), No. 3, pp. 148-156).—Comparisons of the kaolin, paper coil and Gottlieb methods of milk analysis for whole milk, skim milk, and buttermilk.

The introduction of a uniform method for determining fat in milk, M. WEIBULL (*Milch Ztg.*, 27 (1898), No. 26, pp. 406, 407).—An address delivered by the author at the second Norwegian agricultural congress. After discussing the various volumetric and gravimetric methods, he concludes that the choice of a "normal" method for milk control lies between the Adams gravimetric method and Gottlieb's modification of Röse's (volumetric) method, "as both of these gave uniform results when used by different persons."

Machine for rapidly calculating the total solids in milk from the specific gravity and fat content (*Milch Ztg.*, 27 (1898), No. 29, pp. 456, 457, fig. 1).—A description of a milk scale in the form of a disk, devised by E. Ackermann.

The calculation of "added water" in adulterated milks, H. D. RICHMOND (*Analyst*, 23 (1898), July, pp. 169-174).

On the determination of malic acid in raisins, A. GIRARD and L. LANDET (*Bul. Soc. Chim. Paris*, 3. ser., 19 (1898), No. 13, p. 585).

Standard methods for the sampling and analysis of tanning materials, H. R. PROCTER and J. G. PARKER (*Jour. Soc. Chem. Ind.*, 17 (1898), No. 1, pp. 6-10).

The effect of different temperatures in the extraction of tanning materials, J. G. PARKER (*Contrib. London Leather Industries Research Lab.*; *abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 2, pp. 106-110).

The nicotine content of cigars and smoking tobacco sold at retail, H. SINNHOLD (*Arch. Pharm.*, 236 (1898), No. 7, pp. 522-529).

The development of official methods of agricultural analysis, J. HENDRICK (*Jour. Soc. Chem. Ind.*, 17 (1898), No. 4, pp. 326-330).—Attention is called to the lack of uniformity in official analytical work in England, and the systems evolved in the United States and Germany are explained.

Uniform methods for the analyses of foods, condiments, and commercial products in the German Empire, J. SPRINGER (*Vereinbarungen zur einheitlichen Untersuchung von Nahrungs- und Genussmitteln sowie Gebrauchsgegenständen für das Deutsche Reich*. Berlin: 1897, pt. 1; *abs. Ztschr. Fleisch u. Milchhyg.*, 9 (1898), No. 1, p. 18).—Among the subjects treated are general methods of analyses, preservatives, meat, sausage, meat extract, peptones, milk, eggs, cheese, and fats and oils.

Second meeting of the international commission for uniform methods of sugar analysis (*Chem. Ztg.*, 22 (1898), No. 64, p. 652).—An account of the meeting held at Vienna, July 31, 1898.

The analysis of food and drugs: I. Milk and milk products, T. H. PEARMAIN and C. G. MOOR (*London: Baillière, Tindall & Cox*, 1897; *rev. in Analyst*, 23 (1898), Aug., p. 224).

Report of the chemical station and seed-control station at Skara (Sweden) for 1897 (*Skara: Sken Hammar, 1898*).

Report of the Swedish chemical stations for 1896 (*Meddel. K. Landtbr. Stry., 7 (1897), No. 42, pp. 280-313*).—Eight State chemical stations were in operation during 1896, and 6 additional stations were supported by as many county agricultural societies. At the State stations 43,551 samples were analyzed in all during the year, of which 36,569 were dairy products, principally milk; 1,201 were fertilizers; 568 soil samples; 3,585 were examined for poisons, etc. The county stations analyzed in all 21,524 samples, 90 per cent of which were dairy products.

A monthly summary is given of milk analyses made at Vesteras Chemical Station during 1896, including 17,166 analyses. The average for the year was 3.35 per cent of fat.—F. W. WOLL.

BOTANY.

On the nitrogen assimilation of plants, L. LUTZ (*Compt. Rend. Acad. Sci. Paris, 126 (1898), No. 17, pp. 1227-1229*).—The author briefly reviews the work of a number of investigators in this line and states that Ville has shown that plants are able to assimilate methylamin and ethylamin, but his conclusions were subject to error on account of the fact that no attempt was made to exclude micro-organisms. Frank is stated to have shown that leucine, tyrosine, and alkaloids are not assimilable. Bokorny has stated that *Spirogyra* is able to grow in a nutrient solution containing trimethylamin sulphate. On the other hand, Réveil has claimed that alkaloids are poisonous to plants, while Cornevin and Heckel have shown that under certain conditions they may be utilized.

The author describes in considerable detail his experiments and in conclusion states that phanerogams are able to assimilate their necessary nitrogen from amines in the form of salts without those substances being transformed into ammonium salts or nitrates. For this assimilation it is necessary that the amines should be presented in a comparatively simple form. Methylamin has proved an excellent source of nitrogen, while benzylamin, pyridin, glycolamin, and betaïn are unassimilable. Phenolamin is said to be very poisonous and the compound ammonium salts and alkaloids are not directly assimilable. In most cases where the nutrient solution contained nitrogen in an unassimilable form the plants lost a considerable amount of their initial nitrogen. In this connection the author states that their period of growth was prolonged considerably beyond what it would have been under ordinary conditions without the intervention of micro-organisms, and the question is raised whether or not there was not some form of self-fermentation present. The author sought to ascertain the form in which the nitrogen disappeared from these plants, and claims that his investigations showed that it was liberated in a gaseous state.

Influence of diffused light on the development of plants, J. WIESNER (*Compt. Rend. Acad. Sci. Paris, 126 (1898), No. 18, pp. 1287-1289*).—The author reports a series of experiments with *Impatiens balsamina*, *Keseda odorata*, *Tropæolum majus*, and *Ipomœa purpurea*, which

were planted after germination on slopes with north, east, south, and west exposures. The plants on the north exposure received an average of $\frac{1}{42}$ of the total illumination of the sun. All of the 4 species planted bloomed on the north exposure. The Impatiens, Tropaeolum, and Ipomœa had well-developed and abundant flowers. The Reseda flowers were few and the inflorescences small. All of the plants fruited and produced viable seeds. The plants given a southern exposure flowered much earlier, the Reseda exceeding the plants grown with north exposure by 6, the Impatiens by 13, the Tropaeolum by 16, and Ipomœa by 17 days.

The author's experiments seem to show that the 3 rather dissimilar families of plants represented are able to completely develop in diffused light.

Analogous experiments with *Sedum acre*, a species of plant which usually grows in sunny exposures, showed that the vegetative growth of the plant developed in the northern exposure, but the plant did not flower. It is evident that $\frac{1}{42}$ of the intensity of light is not sufficient for the development of this plant.

On the direct fertilization of plants whose flowers seem adapted to cross fertilization, C. GERBER (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 21, pp. 1731-1737).—The author claims that by the peculiar form of the calyx of *Cistus albidus* the plant is close pollinated instead of cross pollinated, as would seem to be indicated from the structure of the flower. The same has been observed in other species of this genus, namely, *C. salicifolius*, *C. hirsutus*, and *C. villosus*.

Penicillium as a wood-destroying fungus, H. MARSHALL WARD (*Gard. Chron.*, 3. ser., 21 (1898), No. 612, pp. 221, 225).—A brief abstract is given of a paper read by the author before the botanical section of the British Association. It is stated that—

“Spores from pure cultures of *Penicillium* sown on sterilized blocks of spruce wood, cut in March, were found to grow freely and develop large crops of spores on normal conidiophores. Sections of the infected wood showed that the hyphæ of the mold entered the starch-bearing cells of the medullary rays of the sapwood and consumed the whole of the starch. The resin was untouched. In cultures three months old the hyphæ were to be seen deep in the substance of the wood passing from tracheid to tracheid *via* the bordered pits. Control sections, not infected and kept side by side with the above, contained abundance of starch and no trace of hyphæ could be detected in them. The observation appeared of interest in several connections. *Penicillium* was one of our commonest molds and undoubtedly played a part in the reduction of plant debris to soil constituents; how far it could itself initiate the destruction of true wood, or how far it merely followed on the ravages of other fungi, bacteria, etc., was unknown. There were strong grounds for believing that it destroyed the oak of casks, etc., but since these were impregnated with food materials, that was not very surprising. It appeared as if *Penicillium* might be a much more active organism in initiating and carrying on the destruction of wood than had hitherto been supposed, and that it was not merely a hanger-on or follower of more powerful wood-destroying fungi.”

Two useful grasses (*Producers' Gaz. and Settlers' Rec.* [West. Australia], 5 (1898), No. 1, pp. 289-291, pls. 2).—Two species of *Paspalum*

(*Paspalum distichum* and *P. dilatatum*) are figured and described. On account of its decumbent habit, the former is said to be specially adapted for covering river banks or water holes and especially as it withstands temporary inundation and keeps green throughout the year. The second species, which has been introduced into Australia from America, has proved an excellent fodder plant, keeping green during the hottest summer and proving hardy at an elevation of 2,000 ft. It is said to be particularly adapted for cultivation in the light sandy soils on account of its root system, which not only secures moisture from the deeper layers of the soil, but also prevents its destruction by grazing animals.

West Australian grasses, F. TURNER (*West Australian Settler's Guide and Farmer's Handbook, 1897, pt. 3, pp. 402-417, figs. 10*).—Of the 119 species of grasses found in western Australia the author states that the most valuable and nutritious species are the following: Six species of *Andropogon*, 3 of *Anthistiria*, 3 of *Chloris*, 5 of *Danthonia*, 2 of *Diplachne*, 8 of *Eragrostis*, 8 of *Panicum*, and 6 of *Poa*, with several species belonging to other genera. Illustrated descriptive notes are given of 9 of the most valuable grasses, viz. *Andropogon bombycinus*, *Anthistiria arenacea*, *A. ciliata*, *A. membranacea*, *Astrichla pectinata*, *Danthonia semiannularis*, *Panicum decompositum*, *P. gracile*, and *Pollinia laeta*.

Plant life, C. R. BARNES (*New York: Henry Holt & Co., 1898, pp. VII+128, figs. 415*).—This attractive little work treats of plant life considered with special reference to form and function. It is designed to show the variety and progressive complexity of the vegetative body, explain the unity of plan in structure and action of the reproductive organs, and to give an outline of the more striking ways in which plants adapt themselves to their environment. The book is intended to be supplementary to laboratory guides and teachers' directions. The work is divided into the following divisions: The plant body, physiology, reproduction, and ecology; with appendices dealing with laboratory studies, directions for collecting and preserving materials, and descriptions of necessary apparatus and reagents.

While the author states that the work is intended for use in secondary schools, it is confidently believed that its introduction into many institutions not desiring to be so classified would be advantageous both to teacher and student.

A revision of the Mexican and Central American species of Galium and Relbunium, J. M. GREENMAN (*Proc. Amer. Acad. Arts and Sci., 33 (1898), No. 25, pp. 455-470*).

Icones fungorum arranged according to Saccardo's Sylloge, A. N. BERLESE (*Phycomyctes, Pt. I. Berlin: Friedlander & Sohn, 1898, pp. 1-40, col. pls. 67*).—This part treats of the *Peronosporaceae*.

Hicoria ovata (*Amer. Florist, 14 (1898), No. 542, fig. 1*).—Brief illustrated notes are given concerning this tree.

Notes on some Japanese Melamporæ, N. HIRATSUKA (*Bot. Mag. [Tokyo], 12 (1898), No. 134, pp. 30-34*).

On the biology and morphology of pollens, A. HANSGIRG (*Sitzber. Bohm. Gesell. Wiss. Math.-Naturw. Cl., 1897, No. 23, pp. 76; abs. in Bot. Centbl., 75 (1898), No. 1, pp. 19-21*).

Symbiosis and parasitism, A. LORENZEN (*Naturw., 47 (1898), No. 23, pp. 265, 266*).

Can isolated chloroplastids continue to assimilate? A. J. EWART (*Bot. Centbl., 75 (1898), No. 2, pp. 33-36*).—The author states that it may be accepted as definitely established that isolated chloroplastids may continue to assimilate for a short time after removal from their parent cell.

Concerning sugar and starch formation in barley and malt, J. GRÜSS (*Wchenschr. Brau.*, 15 (1898), No. 20, pp. 263-275, pl. 1).

A microscopical study of barley during germination, J. GRÜSS (*Gaz. i rasseur*, 1898, No. 550).

The anatomical structure of the beet leaf, G. FROU (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 10, pp. 397-400, figs. 3).

An achromatic light filter for high power microscopic work, G. F. EISEN (*Ztschr. Wiss. Mikros. u. Mikros. Technik*, 11 (1898), No. 4, pp. 441-447).

A new apparatus for the application of the electric current to microscopic objects, A. SCHÄPER (*Ztschr. Wiss. Mikros. u. Mikros. Technik*, 14 (1898), No. 4, pp. 436-441, figs. 5).

The sectioning of seeds, M. B. THOMAS (*Jour. Appl. Micros.*, 1 (1898), No. 2, pp. 32, 33).—Describes method for imbedding and sectioning seeds.

Celloidin imbedding, F. C. HARRISON (*Jour. Appl. Micros.*, 1 (1898), No. 8, pp. 145, 146).—The author briefly describes a method for imbedding hard tissues, woody stems, seeds, etc.

Comparative phenological notes, H. C. IRISH (*Missouri Hort. Soc. Rpt.*, 1897, pp. 325-330).—Tables and charts are given showing the blossoming time of various plants during several successive years.

Experiments in the cross fertilization of salices, E. F. LINTON (*Jour. Bot. [London]*, 36 (1898), No. 424, pp. 122-124).

Protective coloration and bud formation on leaves, L. GEISENHEYNER (*Deut. Bot. Monatschr.*, 16 (1898), No. 7, pp. 132-134).

Adherence to type in seed breeding, W. W. TRACY (*Amer. Florist*, 13 (1898), No. 522, pp. 1311, 1312).—The necessity of having an ideal and keeping strictly to it in seed breeding is pointed out.

A contribution to the study of wheat, K. HUPPENTHAL (*Beitrag zur Physiographie des Weizens*, pp. 19; abs. in *Bot. Centbl.*, 75 (1898), No. 4-5, p. 153).—The effect of removing 7 varieties of French wheats from maritime conditions to a continental climate was studied. Descriptions are also given of 19 native and 2 Tyrolian varieties. The investigations were conducted in the laboratory of the University of Krakau.

Dissemination of plants by stock cars, J. M. BATES (*Asa Gray Bul.*, 6 (1898), No. 2, pp. 35-37).—Shows the manner in which many weeds have been introduced into new localities.

History, uses, and symbolism of plants in ancient and modern times, C. JORET (*Les plantes dans l'antiquité et au moyen âge: Histoire, usages, et symbolism.* pp. XX+504. Paris: Baillon, 1897; abs. in *Bot. Centbl.*, 74 (1898), No. 8, pp. 241-243).

The origin of gymnosperms and the seed habit, J. M. COULTER (*Science*, n. ser., 8 (1898), No. 195, pp. 377-385; also *Bot. Gaz.*, 26 (1898), No. 3, pp. 153-168).—Address of the retiring President of the Botanical Society of America, delivered at Boston, August 19, 1898.

A study of the andrœcium of gymnosperms, E. THIBAUT (*Thesis. Lille*, 1896, pp. 265; abs. in *Bot. Centbl.*, 75 (1898), No. 4-5, pp. 129-131).

Conception of species as affected by recent investigations on fungi, W. G. FARLOW (*Science*, n. ser., 8 (1898), No. 196, pp. 423-435).—Vice-Presidential address before the section of botany of the American Association for the Advancement of Science, August, 1898. The author believes that physiological characters will assume great importance in the characterization of species.

METEOROLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review*, 26 (1898), No. 7, pp. 291-391, charts 12; 8, pp. 343-390, charts 7; 9, pp. 391-437, charts 17).—Besides the usual meteorological summaries No. 7 contains special contributions on Climatology versus meteorology, by M. Whitney; Erroneous conversion

of metric and English barometer readings, by C. F. Marvin; West Indian service, by E. B. Garriott; The Jamaica weather service, by M. Hall; The character of the evening, by P. Connor; Meteorology at Johns Hopkins University, by O. L. Fassig; Tornado at Hampton Beach, New Hampshire, July 4, 1898, by A. E. Sweetland; and notes by the editor on Prof. Mark W. Harrington; ocean temperatures and meteorology; polar versus equatorial climatology; Rockall as a meteorological station; international meteorological symbols; the first Wellman expedition; rainfall measurements on ships; climates of geological ages; barometric readings converted into standard pressures, and bright meteors.

No. 8 contains special articles on Hann's handbook of climatology, by M. W. Harrington; The effect of approaching storms upon song birds, by C. E. Linney; Progress in the exploration of the air with kites at the Blue Hill Observatory, Massachusetts, by L. Rotch; Prof. Park Morrill, by E. B. Garriott and C. Abbe; Destruction by lightning in the State of New York during the month of August, 1898, by R. G. Allen; and notes by the editor on ball lightning; the measurement of the wind; sensible temperatures or the curve of comfort; sensational meteoric story; increase and decrease of fresh-water lakes; heavy rain during hurricane at Port Royal, South Carolina; waterspouts on the lakes; lunar rainbow; earthquakes in Central and South America; the Australian weather guide; ribbon lightning; the kite and telephone; a memorial to Volta, and studies of the Japan current.

No. 9 contains special articles on The probable state of the sky along the path of total eclipse of the sun, May 28, 1900, by F. H. Bigelow; Electric signal apparatus at Atlantic City, New Jersey, by A. Brand; Meteorological observations at Hacienda Perla, Puerto Rico, by A. C. Hansard; Quantity of rainfall corresponding to given depths, by A. J. Henry; Severe hailstorm in Missouri, by A. E. Hackett; The telegraph service with the West Indies, by J. H. Robinson; Aneroid barometers, by C. F. Marvin; and notes by the editor on the Omaha convention of Weather Bureau officials; the weather and the sugar crop; instruction in research; international meteorological symbols, and the second Wellman polar expedition.

Moisture tables, C. F. MARVIN (*U. S. Dept. Agr., Weather Bureau Doc. 171, pp. 9, fig. 1*).—This article, which is reprinted from the *Monthly Weather Review*, May, 1898, gives a table showing the weight of a cubic foot of aqueous vapor at different temperatures and percentages of saturation, and explains the use of the sling psychrometer as well as the method of making observations with it.

Department of meteorology and agricultural engineering, 1896-97, C. H. PETTEE (*New Hampshire Sta. Bul. 48, pp. 148, 149*).—A brief statement of the work of the year in this department of the station.

Meteorological observations (*Massachusetts Hatch Sta. Met. Buls. 115, 116, 117, pp. 4 each*).—These bulletins give the usual summaries of meteorological observations, with general remarks on the character of the weather during the months of July, August, and September, 1898.

AIR—WATER—SOILS.

Salt River Valley soils, R. H. FORBES (*Arizona Sta. Bul. 28, pp. 66-99, map 1*).—This bulletin contains general remarks on the physical and agricultural features of the Salt River Valley, the objects of soil analysis, essential plant food, and interpretations of analyses, accompanied by tabulated analyses of 21 samples of soils from different parts of Salt River Valley.

The average composition of the soils examined is shown in the following table:

Average composition of Salt River Valley soils.

[In fine earth, water free.]

	Per cent.
Organic and volatile matter.....	3.569
Insoluble matter—sand, etc.	61.575
Soluble silica—from clay	13.781
Alumina—from clay.....	6.433
Iron oxid—from clay.....	1.922
Calcium oxid	2.372
Potassium oxid821
Sodium oxid425
Magnesium oxid	1.835
Manganese oxid (Mn ₂ O ₃).....	.055
Phosphoric acid130
Sulphuric acid.....	.059
Carbon dioxide ¹	1.025
Chlorin.....	.110
Total	100.112
Humus650
Nitrogen045
Alkaline salts:	
Total soluble salts167
Sodium carbonate.....	.041
Sodium sulphate.....	.030
Sodium chlorid011

The results indicate that—

“The soils of Salt River Valley, generally speaking, are amply supplied with the more essential mineral (ash) plant foods, including lime, potash, and phosphoric acid.

“Nitrogen and humus are undoubtedly deficient in quantity, and the addition of these soil ingredients is desirable, perhaps imperative.

“Alkaline salts are not prevalent in excessive amount except in occasional localities of limited area. The alkali is very ‘white’ in character and, consequently, its injurious effects are minimum.

“Probably the most serious difficulty with our virgin soils is a physical one. Their dense, compact condition must be remedied by suitable methods of culture.

“The cheapest and best methods of supplying the lack of humus and nitrogen, and of improving the tilth and water-holding power of these soils is by growing

¹ This amount of carbon dioxide calculates to 2.33 per cent of carbonate of lime.

leguminous crops upon the lands and plowing them under as green manuring. So far as now known alfalfa and crimson clover are the best of these, and their use for this purpose is undoubtedly an essential part of any scheme of crop rotation for this region."

Materials for the study of Russian soils, XI, A. SOVYETOV and N. ADAMOV (*St. Petersburg, 1898, pp. 221; abs. in Selsk. Khoz. i Lysor., 189 (1898), Janv. pp. 711, 712.*)—This part contains, among others, the following articles: The influence of the electrization of the soil on the processes which take place in it, by S. Kravkov; the assimilation by plants of the nitrogen of the soil as dependent upon meteorological conditions, by A. Doyarenko; and the absorbing power for phosphoric acid of some Russian soils, by U. Krat.

The first article gives, besides a brief review of literature on the question of electroculture, the results of the author's laboratory investigations relating to the study of the physical and chemical properties of the soil subjected to electrization. The following are the results arrived at: A galvanic current passed through the soil produces a marked influence on many chemical and physical processes taking place in it. First of all its action is shown in an intensified decomposition of the organic matter in the soil, causing the formation of an excess of carbon dioxide, which in its turn acts as a solvent on the constituents of the soil. The increased concentration of the soil solution in its turn (1) decreases the intensity of the evaporation of water by the soil; (2) reduces greatly the capillary power of the soil; (3) lowers to the minimum its percolating capacity; and (4) somewhat alters the character of the structure of the soil, rendering it larger grained. In general, according to the author, the protracted action of the galvanic current may reduce chernozem soils to great poverty in humus and lead to complete exhaustion.

The second article gives the results of experiments by the author with winter wheat, which established the dependence of the assimilation of nitrogen on atmospheric precipitation (in dry weather less nitrogen is assimilated than in rainy weather), as well as a similar connection between this process and the temperature, humidity, and sometimes the barometric pressure.—P. FIREMAN.

Composition of Indian soils, J. W. LEATHER (*Agr. Ledger (Agr. ser., No. 24), 1898, No. 2, pp. 83.*)—According to the author four main types of soils occupy by far the greater part of the cultivated area of India. These are "the Indo Gangetic and other alluvium, the black cotton soil or *regur*, the red soils lying on the metamorphic rocks of Madras, and the laterite soils which are met with in many parts of India. There are doubtless other minor classes of soils, but they neither possess such characteristic differences in appearance, nor are they distributed over such extensive areas as the 4 types referred to." Chemical analyses, descriptions, etc., are given of 22 samples of the first class, 18 of the second, 7 of the third, and 12 of the fourth, besides of 6 samples of coffee soils from Madras, 4 of tea garden soils (with subsoils) from the Dooars, 9 of *bhil* or peaty tea soils, and 3 of *tecla* or poor

sandy soils also used for the culture of tea;¹ and 5 samples of Poona (Manjri) farm soils, 3 (with subsoils) of Nagpur farm soils, 11 of Cawnpur farm soils, and 8 (with subsoils) of Durnraon farm soils.

Analyses are also reported of miscellaneous soils sent to the author for examination, as follows: Three samples of tobacco and onion soils near hot springs (with samples of the water), 3 of soil from the Dholkot forests, 35 of Meerut soils, and 6 of "chhos" (sandy) soils.

In the type soils the proportion of insoluble silicates was very variable.

"In the soils of the great alluvial plains, their amount is much about the same as one is accustomed to find in English loams and clays. In the black cotton soil (*regur*) their amount is uniformly low, due principally to the high proportions of ferric oxid and alumina and the water combined with them, and to a lesser degree to the presence of larger amounts of lime and magnesia than many English loams contain. In the red soils of Madras the proportion of silicates is low in two cases, due to the presence of large amounts of iron and alumina; the other samples contain high amounts. The laterite soils yielded very varying amounts of insoluble silicates, which was due almost entirely to the great variations in the amount of iron and alumina which is a chief characteristic of these soils. In the brown alluvial soils from Madras Presidency, the proportion of silicates is low in the loams, chiefly owing to the high proportions of iron and alumina which these soils contain. In the coffee soils from the Sheveroy the silicates are very small in amount, due in part to high proportions of iron and alumina, but in part also to high proportions of organic matter. In the Assam soils the proportion varies very much, according to the proportion of organic matter present."

The iron and aluminum content was usually high. In the Indo-Gangetic alluvium the iron oxid varied from 2 to 7 per cent, the alumina from 3 to 10 per cent; in the *regur* soils the iron oxid varied from 4 to 11.5 per cent, the alumina from 6 to 14 per cent; in the red Madras soil the iron oxid varied from 3.5 to 10 per cent, the alumina from 1.5 to 15.8; and in the laterite soils the iron oxid varied from 6 to 48 per cent, the alumina from 7 to 14 per cent.

The soils are, as a rule, poor in lime, the alluvium containing from 0.3 to 2 per cent, the *regur* soils from 1 to 7.7 per cent, the red soils, laterites, and Madras alluvium usually less than 1 per cent. The coffee soils had about 0.3 per cent and many of the Assam soils even less. The amount of lime usually present is considered sufficient, especially in view of the fact that the humus content of these soils is, as a rule, quite low.

Magnesia is generally abundant and potash appears to be ample in all classes of soils.

"[Phosphoric acid is usually low]. Of the Gangetic alluvial soils, 6 contained 0.08 or less, 4 contained from 0.09 to 0.13, and only 2, namely, the Changa Manga soil and the calcareous one, both of which had been placed for long periods under influences of accumulation of plant food, contained more than 0.13 per cent. Of the 18 *regur* soils, 16 contained 0.08 or less of this plant food, the other 2 containing about 0.2 per cent. Of the 6 red soils, 4 contained 0.08 per cent or less, the remaining 2, 0.09

¹The data regarding tea soils are quoted from K. Bamber's book "On the Chemistry and Agriculture of Tea."

per cent. Of the laterite soils, 4 contained less than 0.01 per cent, 1 others 0.08 per cent or less, and 4 others fair amounts. The Madras alluvial soils contained, as a whole, somewhat more, there being 0.08 per cent or more in 6 out of 10 samples, but the other 4 contained only very small amounts. The coffee soils have doubtless been well manured, and contained with one exception 0.1 per cent or more. The Assam soils appear to be far better off in respect of phosphoric acid than any other soils in India. In none of those examined could there be said to be a serious deficiency."

By digestion of some of the soils in 1 per cent citric acid, according to Dyer, it was found that "although the Indian soils have frequently or generally a low proportion of total phosphoric acid, it is likely that the proportion of available phosphoric acid is not usually deficient."

With the exception of Assam soils, there is usually little organic matter and nitrogen in Indian soils, under normal conditions.

"Among the soils representing the Gangetic alluvium, 3 out of 10 contain 0.05 per cent or a little more [of nitrogen], the rest less; among the alluvial soils from Madras, 2 contained about 0.1 per cent, and 2 contained about 0.05 per cent, but in the other 6 samples the proportion was much less. Of the 18 samples of regur soils, only 1 contained 0.05 per cent, the other 17 containing less; among the red soils from Madras 1 contained 0.05, the other 5 less; among the 12 laterite soils not one contained as much as 0.05 per cent, and most of them only about 0.03 per cent or less. On the other hand the Assam soils contained uniformly high proportions of nitrogen, and those soils which have had an opportunity of accumulating nitrogen contained very fair amounts. The soils from Partabgarh contained 0.18, the surface soil at Changa Manga 0.237, and the coffee soils from the Sheveroy 0.04 to 0.17."

The judging of the physical properties of soils by means of the heat which they evolve when moistened, A. MITSCHERLICH (*Jour. Landw.*, 46 (1898), No. 3, pp. 255-268).—This is essentially a summary of an inaugural dissertation presented at Kiel in 1898. When dry soils are moistened a certain amount of heat is evolved (*Benetzungswärme*). Wilhelmy¹ has shown that the amount of heat thus evolved depends upon the size, form, and adhesion coefficient of the individual soil particles.

The author undertook to determine whether this property of soils could be used for comparing their physical properties. For this purpose 10 typical soils, classified on the basis of their actual agricultural value as determined in practice, were subjected to mechanical and chemical analysis and also tested with regard to the heat evolved on moistening. The samples used for analysis were put through a sieve having round holes 1.5 mm. in diameter, and air-dried to constant weight. The moisture was determined in 5 gm. of the air-dry material by drying in a vacuum over strong sulphuric acid. The Schloessing method of analysis was followed in the main. Humus, however, was calculated by Wolff's factor, 1.724, from the carbon as determined by Loges' method.² In case of soils rich in humus the portion separated as clay in mechanical analysis contained considerable amounts of humus. A

¹Ann. Phys. u. Chem. [Poggendorff], 119 (1828), p. 177; 122 (1829), p. 1.

²Landw. Vers. Stat., 28 (1883), p. 229.

correction was therefore made for this as determined by loss on ignition. The heat evolved on moistening the soils was determined by means of a Bunsen¹ ice calorimeter as improved by Schuller and Wartha,² the method of procedure being in brief as follows:

The soil was dried over concentrated sulphuric acid. A sample of the dried soil was placed in a suitable glass vessel, which was closed with a stopper carrying a capillary tube, through which the air was exhausted. At the end of this operation the capillary tube was sealed and the vessel containing the soil was cooled and placed in the inner chamber of the calorimeter, which was filled with pure distilled water. The capillary tube was broken under water, thus letting in the water and moistening the soil, and the rise in temperature was noted.

The rise in temperature (uncorrected for errors in manipulation, etc.) varied from 0.001 calorie (small) in tertiary quartz sand to 22.66 calories in moor soils. The heat evolved appeared to be more largely influenced by the stage of decomposition of the humus in the soils than by any other factor. The more advanced the decomposition the higher the temperature noted. There appeared to be no relation between the heat evolved and hygroscopicity.

It is claimed that the determination of the heat evolved when soils are moistened is more easily and correctly carried out than the chemical and mechanical analysis, and that it furnishes more reliable indications of the actual agricultural value of soils.

The carbonic acid of the atmosphere, ALBERT-LEVY and H. HENRIET (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 23, pp. 1651-1653).

Soil temperatures at Lund, Sweden (*Meddel. K. Landtbr. Styr.*, 7 (1897), No. 42, p. 183).—Monthly observations of the soil temperature at one-half and 1 meter depths for the year 1896.

On the differences in temperature of soils with and without vegetation or a covering of snow, H. WILD (*Separate from Mem. Acad. Imp. Sci. St. Pétersbourg*, 1898, pp. 32. *Leipsic*).

Moisture investigations for 1897, E. C. CHILCOTT and A. B. HOLM (*South Dakota Sta. Bul.* 58, pp. 55-84, figs. 5).—This bulletin records the results of the determination of moisture at 4 different depths in 10 tenth-acre plats subjected to different systems of culture—wheat, raked, shallow culture, deep culture, and no cultivation, together with some data relating to the mechanical analysis of the soils of the different plats, the meteorological conditions of the season, and the temperature of the soil at different depths.

On the nitrogenous products which accompany humic acid in peat, F. SESTINI (*L'Orosi*, 21, p. 1; *abs. in Bul. Soc. Chim. Paris*, 3. ser., 20 (1898), No. 13, p. 574).—The author boiled peat for several hours successively with 2 per cent sodium hydrate and

¹ *Ann. Phys. u. Chem.* [Poggendorff], 141 (1870), p. 101.

² *Ann. Phys. u. Chem.* [Wiedemann], n. ser., 2 (1887), p. 359.

10 per cent hydrochloric acid, but succeeded in removing only a small proportion of the nitrogenous substances present, thus showing that amids are not present to any great extent, as is commonly supposed. It was also found that natural humus compound prepared from peat, as well as artificial humus prepared from pure sugar, yielded furfural when heated with hydrochloric acid.

FERTILIZERS.

Experiments with lime on acid soils, F. S. EARLE and A. W. ORR (*Alabama College Sta. Bul.* 92, pp. 107-112, fig. 1).—A brief account is given of experiments in the greenhouse and in the field on the effect of lime on the Gulf sandy coast soils of Deer Park, Alabama. The 3 soils used in the greenhouse experiments were (1) ordinary upland soil of the coast region, quite sandy and rather deficient in humus; (2) so-called "Savannah land," a light gray sandy loam, usually too wet for cultivation without drainage; (3) stiff black soil from a swampy hammock—the low lying timber lands along small streams. The 3 samples represent the prevailing types of coast soils. All of them gave a prompt and decided acid reaction with litmus paper.

"A portion of each lot [of soil] was fertilized with cotton-seed meal and placed in a shallow box, 20 by 36 in., having a partition dividing it into 2 equal parts. On one side of the partition in each box a quantity of slacked lime was dug into the soil, the other side being left without lime. The boxes were watered and left on the greenhouse bench till January 1. On again testing with litmus paper, the limed ends of the boxes now gave a strong alkaline reaction. The boxes were planted to American Wonder peas. It soon became evident that too much lime had been used, for after coming up, the peas in the limed ends of the boxes all died. They did not seem able to strike root in the soil. The boxes were replanted at intervals, but without success, until about the middle of March, when they were planted to lettuce and radishes. On April 2 it was noted that at last a good stand had been secured in 2 of the limed boxes. The one containing the upland soil was still a complete failure. In box No. 3, with the hammock soil, the lettuce was decidedly best in the limed end; no difference could be noted in the radishes. In box No. 2, the Savannah soil, the lettuce was at least 3 times as large in the limed end, while the radishes seemed hardly so good with the lime. The radishes continued to grow luxuriantly in both ends of both boxes, but at maturity they were slightly better in each case in the limed ends. With the lettuce the difference was very marked. In the unlimed ends of both boxes it was stunted and sickly, with leaves less than 2 in. long, but in the limed ends it grew rank and luxuriant."

Experiments were made in the field on upland soil at Deer Park with peas, corn, German millet, tomatoes, beans, ruta-bagas, lettuce, egg-plant, sorghum, peanuts, tobacco, okra, potatoes, flax, Kafir corn, and cucumbers. The soil was limed at rates of from 15 to 45 bbl. per acre. For various reasons the results with the majority of the crops were inconclusive. Corn, tomatoes, lettuce, and tobacco, were, however, strikingly benefited by liming. It was noted that the tomatoes on the heavily limed plat were free from blight or bacteriosis.

On the influence of crops and manure on the nitrogen content of soils, C. F. A. TUXEN (*Tidsskr. Phys. og Chem.*, 2 (1898), p. 168; *abs. in Chem. Ztg.*, 22 (1898), No. 71, *Repert.*, p. 219).—The experiments made by

the author lead to the conclusion that the nitrogen content of soils is increased by culture of leguminous plants due to the assimilation of the free nitrogen of the air by such plants. Grass is especially effective in protecting the soil from loss of nitrogen by washing and by decomposition. The cereals, on the other hand, rapidly reduce the nitrogen content of the soil. Experiments during from 20 to 30 years with different kinds of fertilizers and manures have shown that the application of commercial fertilizers containing nitrogen does not increase the store of nitrogen in the soil. The use of barnyard manure, however, has, in every case, resulted in a decided increase in this respect.

On the production of barnyard manure, P. GAY and DUPONT (*Ann. Agron.*, 21 (1898), No. 3, pp. 123-130, fig. 1).—For the purpose of determining the comparative losses of nitrogen when manure is removed from stables only at long intervals and when it is removed daily, the authors first determined the amount of nitrogen consumed in the food and excreted in the urine and feces of a sheep during 7 days. The food used was alfalfa and oats. The feces and urine were collected by means of rubber bags and harness. The total nitrogen in the food consumed during the 7 days was 171.1 gm. The amount excreted (98 gm. in the urine and 65.4 in the feces) was 163.4 gm. The amount of nitrogen not recovered in the urine and feces was therefore 7.7 gm. or 4 per cent of the amount in the food.

In the second experiment the same animal was kept for 14 days in a stall, being supplied each day with sufficient litter to absorb all urine. The nitrogen in the food consumed was 345.1 gm., in the litter used, 53.1 gm., and in the manure produced, 321.9 gm. The loss of nitrogen was therefore 76.3 gm. or 22 per cent of the original nitrogen. These results confirm in general those obtained by Müntz and Girard (*E. S. R.*, 4, p. 686.)

Fertilizers (*New Jersey Stas. Rpt. 1897*, pp. 15-75).—Much of the data in this article has already been published (*E. S. R.*, 9, p. 934). Statistics are given showing the quantity and value of fertilizers used in New Jersey in 1896, and comparing the trade of this year with that of preceding years. The market prices of various fertilizing materials are reviewed, with trade values of fertilizing ingredients for 1897; and analyses and valuations are given of 453 samples of fertilizing materials, including nitrate of soda, sulphate of ammonia, dried blood, dried and ground fish, tankage, ground bone, dissolved boneblack, dissolved South Carolina rock and other mineral phosphates, muriate of potash, sulphate of potash, kainit, double sulphate of potash and magnesia, wood ashes, tobacco stems, marl, garbage fertilizer, wool combings, screenings, mussels, granulated tobacco and sulphur, and home-mixed and factory-mixed fertilizers.

From replies to a circular sent to firms selling fertilizers in New Jersey it appears that the total consumption of fertilizers in the State during 1896 was 56,355 tons, valued at \$1,612,718, complete manures representing 77 per cent of the total amount and 81 per cent of the total

value of all sales. The sales reported in 1896 were larger than those of any previous year. A comparison of the average composition of the 331 fertilizers examined in 1896 with the averages for previous years "indicates that no decided change in the average quality of fertilizers has occurred during the past 12 years."

A review of market prices of fertilizing materials for 7 years shows that the difference between the wholesale and retail prices of nitrogen in 1896 was 19.3 per cent. "This is a marked decrease from that of last year, but is still too great. It is largely due to the low wholesale prices which ruled for all ammoniates during 1896. In the case of available phosphoric acid the difference is nearly 90 per cent greater than in 1895, while in potash there is a decrease of over 12 per cent." The average valuation of mixed fertilizers remains about the same as in previous years. "The average selling price, however, is now lower than ever before, which reduces the amount of average charges for mixing, bagging, shipping, and selling to \$7.70 per ton, or 35.7 per cent, which is less in amount than in any of the previous 6 years." The average composition of 35 samples of ground bone examined during the year was: Nitrogen, 3.51 per cent, and phosphoric acid, 24.67 per cent, the average retail selling price being \$28.88. Ten of the 35 samples failed to reach their guarantees in either nitrogen or phosphoric acid and 1 was low in both constituents. With one exception, however, any deficiency in one element was more than made up by an excess in the other.

Algerian phosphate production (*Engineer. and Mining Jour.*, 65 (1898), March 12, p. 313; *abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 3, p. 291).—Statistics are reported which show that the shipment of Algerian phosphate from the port of Bône in 1897 was 207,083 metric tons as against 110,040 tons in 1896. England, France, Germany, and Italy, with 73,430, 70,155, 24,770, and 18,950 tons, respectively, were the largest consumers of this product.

Sulphate of ammonia production (*Engineer. and Mining Jour.*, 65 (1898), June 18, p. 730; *abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 6, p. 622).—The production of this material in Great Britain in 1897 is stated to have been 198,280 long tons, and in the United States 3,111 tons.

Nitrate of soda and sulphate of ammonia (*Bradbury and Hirsch's Report; W. Montgomery & Co.'s circular; abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 1, pp. 84-86).—Statistics of consumption, prices, etc., for the period from 1893-1897.

Experiments with potassium perchlorate, JUNGER and M. GERLACH (*Jahresber. Landw. Vers. Stat. Jersitz-bci-Posen, 1897-98*, pp. 29-33).

On the agricultural value of Solvayhall "hartsalz," M. MAERCKER (*Illus. Landw. Ztg.*, 18 (1898), p. 618; *abs. in Chem. Ztg.*, 22 (1898), No. 71, *Repert.*, p. 219).—This salt, which is rich in chlorine, was compared with kainit and sulphate and chlorid of potash in pot and field experiments. As a rule the hartsalz gave larger yields than kainit, more potash but less chlorine being taken up by plants in case of the former than in case of the latter. The potash in the hartsalz appeared to be fully as soluble as that in kainit and more soluble than that in sulphate.

The law of the minimum and the effects of excessive liming, L. GRANDEAU (*Jour. Agr. Prat.*, 62 (1898), II, No. 38, pp. 405-407).—Attention is called to the necessity of keeping limed soils well supplied with phosphoric acid, potash, and especially nitrogen.

A special method of applying fertilizers by diffusion, A. HÉBERT and G. TRUFFAUT (*Bul. Soc. Chim. Paris, 3. ser., 19 (1898), No. 11, pp. 651-655*).—The method tested by the author consists in mixing the soluble fertilizing materials with variable amounts of inert substances, such as kaolin, or clay, and pressing the mixture into pellets, which are buried in the soil either without an envelope or wrapped in different numbers of layers of metallic foil. The results indicate that by this method the rate of diffusion of the fertilizing material may be controlled.

On the control of fertilizers during 1897, M. WEIBULL (*Contribution from Alnarp laboratory IX; Tidskr. Landtmän, 19 (1898), No. 5, pp. 75-78*).

Tabulated analyses of commercial fertilizers, T. J. EDGE and W. FREAR (*Pennsylvania Dept. Agr. Bul. 37, pp. 40*).—This bulletin gives the text of the State fertilizer law, notes on valuation, and tabulated analyses and valuations of 588 samples of fertilizing materials inspected during the period from January 1 to August 1, 1898.

Analyses of commercial fertilizers, B. W. KILGORE ET AL. (*Mississippi Sta. Spec. Bul. 49, pp. 27*).—This bulletin reports analyses and valuations of 176 samples of fertilizing materials inspected by the State chemist during the season of 1897-98, introduced by explanations of terms used in stating the results of analyses, notes on the valuation of fertilizers, and the text of the State fertilizer law.

Analyses of fertilizers, C. A. GOESSMANN (*Massachusetts Hatch Sta. Bul. 51, pp. 12*).—Trade values of fertilizing ingredients in 1897 and tabulated analyses of 94 samples of fertilizing materials, including muriate and sulphate of potash, ashes, sulphate of ammonia, ground tobacco stems, cotton-seed meal, bone, ground fish, whalebone scrapings, manure, barnyard manure, and mixed fertilizers.

Analyses of fertilizers, C. A. GOESSMANN (*Massachusetts Hatch Sta. Bul. 54, pp. 24, pl. 1*).—This bulletin gives a schedule of trade values of fertilizing ingredients in raw materials and chemicals in Massachusetts for 1898 and tabulated analyses of 166 samples of fertilizing materials, including wood ashes, lime-kiln ashes, ashes from garbage crematories, phosphatic slag, bleachery refuse, meat meal, blood and bone, tankage and ground bone, cotton-seed meal, tobacco refuse, wool waste, "teopik" fiber, mixed feed, broom-corn seed, acid phosphates, nitrate of soda, muriate of potash, sulphate of potash, and mixed fertilizers.

FIELD CROPS.

The effect of certain methods of soil treatment upon the corn crop, T. L. LYON (*Nebraska Sta. Bul. 51, pp. 77-89, map 1*).—This bulletin discusses the moisture conditions of the State, gives a geological classification of the soils of Nebraska, and reports the results of experiments on subsoiling, fall and spring plowing, deep and shallow plowing, and subsurface packing for corn. Comparisons were made of listing and check-rowing the crop, and giving deep and shallow cultivation.

Experiments in subsoiling have been carried on for several years and some of the results have been previously reported (*E. S. R., 7, p. 847*). The results obtained at the station on a loam containing alkali and underlaid with a compact subsoil showed that subsoiling increased the yield in most cases, but when the season was very wet spring subsoiling failed to show any benefit. Subsoiling in western Nebraska, where the subsoil was loose and porous, reduced the yield by about one-half. The results of subsoiling obtained by farmers throughout the State are reported. On clay subsoil 80 per cent of these trials were favorable to subsoiling, but on a loam subsoil only 23 per cent. In 8 cases of the 59

reported the effect of subsoiling was unfavorable the first year, but favorable afterwards, and in 4 cases the beneficial effect disappeared by the third year.

Fall plowing gave better results than spring plowing, but in 2 of the 4 tests made the results were nearly alike. On the soil at the station plowing early in the fall or in the summer was more effective in increasing the yield than plowing late in the fall. "If the plowing be done in the fall the soil is well compacted by spring, which is doubtless the main reason that fall plowing of this soil produces better results than spring plowing." Land plowed 4 in. deep, both in the fall and in the spring, gave a better yield than land plowed 8 in. deep. It was found that discing 3 in. deep for corn in the fall gave better returns than discing 6 in. deep, but it was not as effective as shallow plowing.

Subsurface packing the soil at the station according to the Campbell method of soil culture decreased the yield when it was done in the fall, but produced an increase when done in the spring. The process of subsurface packing is described.

At the station corn planted in rows both ways on land plowed 8 in. deep yielded 30 bu. per acre and listed corn yielded 18 bu., while on light soil in the western part of the State listed corn yielded 40 bu. per acre and corn grown by the other method 38 bu. Cultivating corn during its growth to a depth of 3 in. gave much better results than cultivating about 6 in. deep.

Preservation of corn stover, D. O. NOURSE (*Virginia Sta. Bul. 73, pp. 15-18*).—This article is a brief discussion on the preservation of corn stover, with directions for cutting, shocking, and storing. The experience of the station has been that shocks made 12 hills square are most economical in every way. Fodder has been kept in the rick all winter covered with but a little straw and was found in perfect condition when placed in the barn the following spring. "To keep it thus . . . time must be allowed for the fodder to cure in the field and it must be placed in the barn or rick entirely free from moisture."

An experiment with clover, F. W. RANE (*New Hampshire Sta. Bul. 48, pp. 122-125, figs. 3*).—In 1896 clover was grown from spring seeding on 2 plats each located in a well-fertilized field. One of the plats had been in corn the year previous, while the other had not produced a hoed crop. The seed sown per acre consisted of 3 pk. of barley, 5 lbs. alsike clover, 7 lbs. red clover, 5 lbs. redtop, and 12 lbs. of timothy. "When the barley, which was used for the protective crop, was cut for hay the clover had made an excellent growth." The field which had produced corn the year before yielded at the rate of 8,835 lbs. of hay per acre, and the other field gave a yield of 9,360 lbs. per acre.

A preliminary report on the experiments with forage crops, T. L. LYON (*Nebraska Sta. Bul. 53, pp. 65-76*).—This bulletin discusses the forage conditions of the State during the summer months and

reports the results of experiments in pasturing and in growing a number of forage crops for pasture and soiling purposes. Descriptive and cultural notes are given for each crop. A two-year-old heifer, not giving milk and weighing about 800 lbs., was pastured on plats of rye and sorghum to ascertain the amount of land required to sustain a cow during summer. The results obtained are given in the following table:

Length of time an acre of rye or sorghum furnished pasturage for one cow.

	Pasturage per acre for 1 cow.		Pasturage per acre for 1 cow.
	<i>Days.</i>		<i>Days.</i>
Rye (winter rye sown in spring).....	129	Sorghum 5 ft. high.....	127
Sorghum 2½ ft. high.....	90	Sorghum, heads formed.....	59
Sorghum 3½ ft. high.....	109	Sorghum, seeds ripe.....	72
Sorghum 4½ ft. high.....	127	Sorghum, second growth.....	136

Among the forage crops tested sorghum, red and white Kafir corn, Canada field peas, hairy vetch, burnet, Jerusalem corn, millo maize, soja beans, and cowpeas are considered adapted to the climate and the soil and of some value as forage. The yields and the food ingredients per acre produced by some of these crops are given in tables. The significance of the different food constituents is explained in a popular way.

On the change of the composition of green fodders at different periods of vegetation, P. AZARJEVICH (*Zap. Novo-Alexandria; Inst. Selsk. Khoz. i Lyesor., 10 (1897), No. 2, pp. 19-21*).—A small plat of ground was sowed with *Vicia narbonensis*: the development of the plants proceeded normally. The *Vicia* was mowed at intervals of 2 weeks, and the plants were dried and analyzed. The author concludes that the content of the crude protein in *Vicia* continually decreases during the period of vegetation.

The amount of albuminoids gradually decreases with age, but in comparison to the crude protein it increases. This is explained by the transformation during growth of nonalbuminous bodies into albuminous, a transformation which is less pronounced in the case of *Vicia* than in that of the Gramineae.

Concerning the ash, no regularity was observed in the change of the percentage content until flowering, after which period there was a continual decrease.

The content of fat remained unchanged until flowering, after which it gradually decreased.

The amount of cellulose continually increased with the growth of the plants.

There was a continual though slight increase in the nitrogen-free extract.

The sum of the nitrogen-free extract plus the fat increases until flowering, but decreases after flowering. This is in entire agreement with the results of E. Wolf and Ritthausen, who experimented with red clover and alfalfa.—P. FIREMAN.

Cooperative fertilizer experiments with cotton in 1897, J. F. DUGGAR (*Alabama College Sta. Bul.* 91, pp. 13-103).—Fertilizer experiments were made in 30 localities of the State to determine the best fertilizer for the different soils. Of the reports received 20 gave definite indications, and these are discussed at length and tabulated in detail, while those deemed inconclusive are considered briefly. Similar experiments were conducted in 1896 (E. S. R., 9, p. 126).

In all experiments cotton seed meal and acid phosphate were applied at the rate of 200 and 240 lbs. per acre, respectively. Kainit was applied at the rate of 100 and 200 lbs. per acre. The fertilizers were applied singly, in twos, and altogether. The application of 200 lbs. cotton-seed meal, 240 lbs. acid phosphate, and 100 lbs. kainit per acre gave the best financial results in the greatest number of localities.

Seeding grass without grain, C. B. LANE (*New Jersey Stat. Rpt.* 1897, pp. 190, 191).—A grass-seed mixture of red clover, alsike clover, and timothy was sown during the summer on 3 well prepared and manured fields. The first field had been in grass for 4 years, the second had produced oats and potatoes, while the third had yielded a crop of oats. A mixture of ground bone, muriate of potash, and acid phosphate was applied to the different fields at the rate of 400, 250, and 500 lbs. per acre, respectively, but the land which had produced potatoes, having been manured for that crop, received no fertilizer before the grass seed was sown. The first field yielded 3.2 tons of cured hay the following June; the 2 other fields yielded 2.5 and 2.1 tons of hay, respectively.

Commercial fertilizers for potatoes, W. H. JORDAN (*New York State Sta. Bul.* 137, pp. 605-624).—The work here reported is similar to previous experiments (E. S. R., 9, p. 128). Fertilizer experiments including 8 acres of land and 80 plats were made with potatoes on 4 farms on Long Island. Four different fertilizer formulas were applied at the rate of 500, 1,000, 1,500, and 2,000 lbs. per acre. Formula No. 1 consisted of 192 lbs. nitrate of soda, 800 lbs. high-grade dried blood, 570 lbs. acid phosphate, 400 lbs. muriate of potash, and 38 lbs. land plaster, aggregating 2,000 lbs. and containing 6.6 per cent nitrogen, 4.75 per cent available phosphoric acid, and 10.31 per cent of potash. This formula was made up with reference to the composition of the potato plant, excepting that the phosphoric acid was in considerable excess. Formula No. 2 was similar to No. 1 with the exception that the potash was supplied as the sulphate. Formula No. 3 was composed of 127 lbs. nitrate of soda, 440 lbs. high-grade dried blood, 1,000 lbs. acid phosphate, 400 lbs. muriate of potash, and 33 lbs. land plaster, also aggregating 2,000 lbs. This mixture contained 3.8 per cent of nitrogen, 8 per cent available phosphoric acid, and 10.4 per cent potash, and was made up in imitation of a fertilizer much used on Long Island. Formula No. 4 was similar to No. 3 but the potash was supplied as sulphate. In these different formulas approximately one-fourth of the nitrogen was nitric and the rest organic and the phosphoric acid was as largely soluble as possible.

The yields and composition of the crop are given in tabular form. The author summarizes the results as follows:

“The use of 1,000 lbs. of fertilizer per acre gave the greatest profit. The slightly larger yield caused by increasing this application to 1,500 or 2,000 lbs. cost in fertilizer expense considerably more than the market value of the potatoes.

“The fertilizer cost of the increased yield of potatoes where 500 or 1,000 lbs. of fertilizer was used per acre was 20 cts. per bushel in those experiments that proceeded without unfortunate conditions.

“The yield of tubers from the Long Island formula was somewhat larger than from a formula compounded with reference to the composition of the potato plant.

“The evidence obtained in these experiments concerning the relative effect of the muriate and the sulphate of potash upon the composition of the potato tuber is inconclusive.

“The proportions of the valuable plant-food compounds found in the potato tubers were not influenced appreciably by the amount or kind of fertilizer used.”

LINDLEY-COWEN (*West Australian Settler's Guide and Farmer's Handbook, pt. 1, pp. 204 + 23, pls. 10, fig. 1, maps 3, dgn. 1*. Perth: E. S. Wigg & Son, 1897).—An enumeration of the productive possibilities of Western Australia, issued under the direction of the Bureau of Agriculture. Customs, statistics, land laws, and stock quarantine regulations are given in an appendix.

Irrigation (*New Jersey Stat. Rpt. 1897, pp. 103-108, fig. 1*).—A description is given of 2 irrigation plants installed in New Jersey during 1897, one at Vineland and the other at the New Jersey Training School for Feeble-Minded Children. The results obtained with these plants "show that artificial watering can be used to advantage even in a wet season."

HORTICULTURE.

Report of the assistant in horticulture, A. T. JORDAN (*New Jersey Stat. Rpt. 1897, pp. 111-159, pl. 1*).—The treatment given the permanent experimental plats during the year is noted. Yields of 4 varieties of currants and 4 varieties of gooseberries grown on irrigated and unirrigated plats are tabulated. The growth of 3 peach trees set by the Stringfellow method is compared with that of 3 set by the usual method. A study has been started to determine the annual draft of

young fruit trees on the nitrogen, phosphoric acid, and potash of the soil. A table is given showing the weight of the leaves and the total length of growth of branches of various tree fruits for the years 1896 and 1897. A test was made of the effect of irrigation, the relative effect of fertilizers with and without irrigation, and the effect of different fertilizers on strawberries. The yields of the different plats are given in tabular form.

“These results show that in 11 cases the yield is increased by irrigation, while in the other 13 no increase occurs; and that in 2 cases the yield from the plats receiving the complete fertilizer is increased by irrigation, while it is less in the other 4: that with the mixture of bone, potash, and acid phosphate the yield, with one exception, is increased by irrigation, while when nitrate of soda is added to the complete fertilizer, only 1 instance of increased yield occurs.”

The effect of nitrate of soda was shown in darker foliage and almost entire freedom from rust. The different fertilizers both with and without irrigation did not appreciably influence the time of ripening. In connection with the irrigation tests the daily and monthly rainfall of the years 1896 and 1897 is recorded.

A comparison was made of hill culture with matted-row culture of strawberries. The plants of 5 plats were grown in hills varying from 12 to 24 in. apart each way. The plants of the other 3 plats were set 18 in. apart in rows 4 ft. apart. In one of these plats all the runners were allowed to grow and form a matted row. In another one-half of the runners were removed, and in a third but 2 plants were allowed to grow from each one set. The varieties grown were Lady Thompson, Greenville, and Gandy. The yields per plant, per plat, and per acre, are given in tables. In the case of hill culture the largest yields were obtained from the plats in which the plants were set 12 in. apart and with 2 exceptions there was a regular gradation in the yields of all varieties from the 12 in. plats to the 24 in. ones. The maximum yield per hill was obtained from the 15 in. plat. The 12 in. plat yielded more than any of the systems of matted-row culture. Of the latter the plat in which all runners were allowed to remain gave the largest yield and the one in which only 2 plants were allowed to form from each one set gave the smallest yield. There was no constant difference in size of fruits between the hill and matted-row system of culture. With the varieties Greenville and Gandy the matted-row plats gave the greatest early yield, while with the variety Lady Thompson the reverse was true.

A test of 31 varieties of strawberries is reported, the results being given in tables, showing early yield, total yield, size of fruits, production of runners, and freedom from rust. A few of the newer varieties are described.

Practical suggestions as to methods of management of apple orchards are reprinted from Bulletin 119 of the station (E. S. R., 9, p. 47), which gives data regarding apple culture obtained from a fruit survey of the State in 1895. Statistics on strawberries, raspberries, blackberries, currants, and gooseberries were gathered at the same time and are

reported in the present publication. Each of the fruits is considered separately. The number of growers using clay-loam soils and sandy soils, and the average yields on both soils in the years 1893 and 1894 are reported. The heavier soils as a rule gave considerably larger yields than the light ones. The number of varieties of each fruit grown in the State is noted, and a list of the varieties most grown in the different sections of the State is given, together with the number of growers reporting each variety. The report also records and discusses statistics in regard to methods of cultivation, manuring, the prevalence of insect enemies and diseases, the average yields, expenses, returns, and like data. Some practical suggestions are given on the culture of the various fruits mentioned.

Experiments in shading. B. D. HALSTED (*New Jersey Stat. Rpt.*, 1897, pp. 344-354, figs. 6).—To test the effect of shade on the prevalence of fungus diseases a number of garden crops were shaded by lath screens. The screens were supported on stakes at various heights above the soil, depending on the size of the plants shaded. Between each 2 laths of the screen an open space equal to the width of a lath was left. The screens were put in position as soon as the seeds were sown.

Shading was found to affect the time of germination of seeds quite noticeably. With the first crop of Lima beans the seeds planted in the open had germinated well by May 26, while under the screens germination had failed almost entirely. The author believes the failure due to the low temperature of the shaded soil. With the second crop, when the conditions were changed, the shaded soil being warm and moist and the exposed soil hot and dry, the beans germinated much sooner in shade than elsewhere. In the case of bush beans observations made May 26 showed that the foliage of the shaded plants was darker in color than that of the unshaded plants, their first pair of leaves were longer, the third leaf was less advanced, the stems were shorter, and the roots had much fewer tubercles. Leaves of shaded turnips were darker green, less blighted, and less hairy than those of the unshaded plants and the roots of the shaded plants were considerably smaller. Shaded potatoes produced weaker vines than others and were kept free from *Phytophthora* longer. Club root of turnips and scab of potatoes was uninfluenced by shading. No marked effects were observed in case of onions. The first crop of peas germinated quicker in the open than under screens. The vines grew somewhat higher and produced fewer pods in the shade than in the full sunlight. The plants of the second crop were less fruitful and also less blighted in the shade than elsewhere; no difference in germination was noticed. Shaded carrots produced more foliage but much smaller roots than unshaded ones. The blight was also apparently checked by shading. Shaded plants of the second crop of lettuce were much larger and better than unshaded ones. The author believes the differences would have been

greater had not the summer been unusually wet and cool, and that shading will be found of great benefit in growing midsummer lettuce. Shading Swiss chard gave results similar to those obtained with lettuce, and in addition reduced the injury from leaf blight. Celery was affected by shading more noticeably than any other plants. "Six varieties were tested in this way and all grew to more than double the size of other plants of the same lot that were in the full sun, but later in the season, with shorter days and less light, the exposed plants overtook and surpassed the shaded ones." With 6 varieties of bush beans the weight of the whole crop of vines and pods of unshaded plants was somewhat greater than of shaded ones, but the weight of pods alone was greater in the case of shaded plants. At the time of harvesting there were 5 times as many ripe as green pods in the sun and not twice as many in the shade. The late varieties held their foliage about equal in both cases, but the early varieties had many more green leaves in the shade than elsewhere. With the second crop of bush beans grown in the same plats as the first the shaded plants were a little later in blooming than the unshaded ones, had fewer and larger leaflets, and were of a deeper green color. The shaded plants were unaffected by the first few frosts in fall, which killed the exposed plants. Other differences were noted with a number of vegetables tested, as diminished thickness of leaves in shade, etc.

The average monthly temperature of the air 1 ft. above the soil is reported to be from 4 to 11.6° cooler under the screens than in the open air, the difference increasing as the summer advanced. The extreme difference ranged from nothing on rainy days to 21° in the hottest clear weather.

Variety tests of fruits, S. T. MAYNARD (*Massachusetts Hatch Sta. Bul. 52, pp. 3-11, fig. 1*).—A report of variety tests of a number of orchard and small fruits is given. Only those varieties found to possess superior qualities are reported. The treatment given each fruit is noted. With some of the fruits the results of the tests are given in tabular form. The following varieties have given the best results: *European plums*.—Czar, Lincoln, German Prune, Kingston. *Japanese plums*.—Red June, Abundance, Georgeson, Burbank, Chebot, Satsuma. *Cherries*.—Early Richmond, Montmorency, Royal Duke, Black Tartarian, Napoleon, Governor Wood, Smidt, Windsor. *Grapes*.—Green Mountain, Herbert, Warden, Moore Early, Concord, Delaware, Brighton. *Currants*.—Cherry, Fay Prolific, Versailles, Red Cross, President Wilder, Pomona, White Imperial. *Gooseberries*.—Columbus, Triumph, Downing, Pale Red, Lancashire Ladd. *Blackberries*.—Snyder and Taylor. *Red raspberries*.—Cuthbert, King, Loudon. *Black raspberries*.—Cromwell, Brackett Seedling, Eureka, Hilborn, Kansas, Lovett, Older, Subegan. *Strawberries*.—Clyde, Brandywine, Boynton, Howard No. 36, Greenville, Glen Mary, and Parker Earle.

To test the keeping qualities of different varieties of apples, specimens grown in 1896 were gathered when in best condition for marketing

and placed in cold storage. The following varieties were in good condition July 1, 1897: Ben Davis, Delaware Winter, Ord Beni, Willow Twig, Whinnery Late, Langford, and Walbridge. Ben Davis, Delaware Winter, and Walbridge were still in good condition February 10, 1898.

A collection of some 350 seedlings of Shaffer raspberries fruited in 1897. The seedlings were grown from seeds taken from the best berries on a row of Shaffer raspberries standing between fields of Marlboro and Thompson Prolific. In regard to the seedlings the author says:

"More than half of the seedlings are of the red raspberry type (*Rubus strigosus*), the majority of the fruits, however, being purple in color like the parent or like that of the old variety Philadelphia, and nearly all were of good size and quality. Many of the plants produced large, well-formed berries of a bright scarlet color and of the best quality. Some show great promise. Among these seedlings were found almost every style of development between the nearly typical form of the blackcap (*Rubus occidentalis*) and that of the wild red raspberry (*R. strigosus*), and also a few albino or white or yellow forms of both species."

To determine whether heading in plum trees while dormant or while in the early stages of growth give best results, 10 trees, 2 each of 5 varieties, were selected and 1 tree of each variety was severely headed in March 30 and the second May 22. The trees pruned in winter made a vigorous growth of a few shoots while those pruned in summer made a fair growth of many shoots. The winter-pruned trees developed a fair quantity of fruit buds while the summer-pruned ones developed a large quantity of fruit buds.

Hardy apples for cold climates, F. A. WAUGH (*Vermont Sta. Bul.* 61, pp. 19-32, figs. 6).—The author discusses the northern progress of apple culture and considers that the factors in this progress have been the planting of crab apples and dwarf apples, the introduction of Russian varieties and especially the selection of native hardy seedlings, and the adoption of better orchard practices. The Russian apples are characterized, their favorable and unfavorable qualities contrasted, and a brief historical account of their introduction into the United States is given. The present status of apple culture in Vermont as regards hardiness of trees was investigated. A map of the State is given, showing the general limit of the successful culture of Baldwin and Rhode Island Greening apples. A number of varieties of apples are arranged according to their hardiness. To grow a given variety north of its natural limit it is recommended to top graft it on a hardy variety and to choose a protected situation with a favorable exposure.

Descriptive notes are given on a number of hardy varieties. For planting where hardiness is the principal consideration the bulletin recommends Yellow Transparent, Red Astrakan, Long Field, Oldenburg, Famense, McIntosh, Wealthy, Scott Winter, Pewaukee, and Arctic.

Some results following the application of wood ashes in the apple orchard, S. A. BEACH (*New York State Sta. Bul.* 110, pp. 681-690).—Experiments in the use of wood ashes in apple orchards were

carried on for 5 years. An old orchard which had previously been in sod was divided into 8 sections, to 4 of which ashes were applied annually at the rate of 100 pounds per tree. Tables are given comparing the yield and keeping qualities of apples grown on treated and untreated sections. The relative resistance of a number of varieties to apple scab is also tabulated. The author summarizes the work as follows:

“On the treated sections of the orchard the foliage in many cases was improved, but it can not be said that the improvement was due to increased immunity from the scab.

“When the ashes were used the color of the fruit was much improved in some seasons with some varieties, but in a season which favored the perfect development of the fruit none of the varieties showed any improvement in color as compared with the same varieties on untreated sections.

“Apparently the use of ashes had a general tendency to hasten the perfect development of the fruit. When the season was not especially favorable to the perfect development of the fruit it improved the keeping quality, but in a season very favorable to the perfect development of the fruit the ripening processes were generally carried so far, where the ashes were used, that the apples did not keep so well as where no ashes were used.

“The yield, except with the Baldwins, was greater on the treated sections; but the data are not such as to make it safe to draw definite conclusions as to the effect of the use of ashes on the yield.

“Decided differences were shown between varieties as to the ability to resist scab, and preliminary investigations indicate that this difference in resistant power is correlated with structural peculiarities.”

Fourth report upon chrysanthemums, W. MILLER (*New York Cornell Sta. Bul. 117, pp. 657-689, figs. 12*).—The author discusses the economic status of the chrysanthemum, stating that chrysanthemum growing in New York probably involves more capital than peach growing. The chrysanthemum has come to be one of the four main florist's flowers. Suggestions are given on growing chrysanthemums at home. The method of procedure depends largely upon the type of plant desired. The use of crown and terminal buds in the production of exhibition flowers is discussed. The terms as used in chrysanthemum culture are distinguished as follows: “A crown bud is surrounded by vegetative shoots and not by other buds. A terminal bud (in chrysanthemums) is surrounded by other buds and not by vegetative shoots.” With some varieties the foliage and form and color of the flowers are very noticeably affected by the choice of the terminal or crown buds. The chief merits of crown buds are earliness and large size. In all other respects terminal buds are likely to be superior. A number of references to the literature of the subject of crown and terminal buds are given.

The problem of control of color of chrysanthemums is discussed. In regard to the factors of the problem the author says:

“The choice of buds is said to be sufficient in some cases. Thus, J. H. Woodford is advertised as shell-pink from terminal and pure white from crown buds. Over-propagation is generally believed to weaken colors. Temperature and ventilation (the two factors can hardly be separated in greenhouse practice throughout the

entire year) are advertised to produce three distinct and desirable shades in Mrs. Col. Goodman. Mere position (in pots, beds, or benches) should not in itself make a difference, but in practice it does. The effect of shade is variously stated. And, most complicated of all, the food factor is known to influence color, but just how is a mystery."

Two of the factors were tested, namely, "whether shading the flower beds would make the flowers a lighter or darker pink, and whether a liberal supply of nitrogen would weaken or deepen the colors." In the shading test 24 plants were exposed to the sunlight at every stage of their growth, and 36 were shaded by means of a rather heavy coat of whitewash applied to the glass directly over them. The flowers of some varieties had begun to open before the whitewash was applied, while the flower buds of other varieties were about the size of marbles when shading was begun. The shading was continued until the flowering season was over. In the nitrogen experiment 23 plants were given the ordinary amount of nitrogen and 37 plants were given in addition a solution of nitrate of soda at intervals of from 3 to 4 days from the time the plants were well rooted until the flower buds began to form. As to the results the author says:

"Shade is said by some to deepen the color, but the reverse was true in this case. The difference was perceptible at once in 5 varieties (Mrs. Perrin, Madame Felix Perrin, Marie Vallean, Helen Bloodgood, and Iora) and at second glance in 2 others (William Simpson and Maud Dean). In only 2 cases, however, was this difference enough beyond question to destroy their salable character, but they are the most important varieties in the list. Mrs. Perrin and Madame Felix Perrin are among the most important midseason commercial sorts of the day. They are so much alike that only an expert can tell them apart. Their peculiar charm is their sparkling, bright rosy-pink color. The flowers of these 2 varieties, whose buds were shaded, were very uneven in color. The loss of color was the only loss, and it alone was enough to destroy their salable character. This can not be attributed to a general lack of vigor in the plants. The experiment shows clearly that during the reproductive phase the forming flowers are extremely sensitive to shading and are sometimes practically ruined by it. There was only one contradictory plant among 26 that were strictly comparable. . . .

"The results of the nitrogen experiment were not certain enough to be published, but it is safe to say that the extra amount of nitrogen did not seem to deepen the color in any case."

Notes are given on a test of a considerable number of varieties of chrysanthemums in 1897. The 10 varieties considered best of those tested are Midge, Geo. S. Kalb, Dr. C. H. Parkhurst, Wm. J. Bryan, Golden Trophy, Elvena, Wood's Pet, Leonidas, Loantika, Casco.

Bul.* 62, pp. 35-44, figs. 10).—The bulletin gives directions for the culture of grapes in Vermont and descriptions and illustrations of a number of varieties. As the result of tests the following varieties are recommended: Moor Early, Worden, Moyer, Brighton, Wyoming Red, and Green Mountain.

Viticulture in Beaujolais (*Une exploitation viticole en Beaujolais. Macon: Protat Frères, 1898*, pp. 31, pls. 13).

Pruning, A. DESPIS (Producers' Gaz. and Settlers' Rec. [West. Australia], 5 (1898), No. 4, pp. 241-259, figs. 25).—A popular article on pruning grapes.

The papaw, A. MORRISON (Producers' Gaz. and Settlers' Rec. [West. Australia], 5 (1898), No. 4, pp. 292-294, fig. 1).

On the promotion of flowering and change of color in flowers, M. MIYOSHI (*Bot. Mag. [Tokyo]*, 12 (1898), pp. 35-43).

The species of azalea, W. J. BEAN (*Garden*, 54 (1898), No. 1403, pp. 282-284, figs. 2, pl. 1).—Notes on the ornamental qualities and culture of several species of rhododendrons and azaleas.

A new species of catasetum, with remarks about the genus, O. AMES (*Amer. Gard.*, 19 (1898), No. 201, pp. 741, 742).

The clematises, J. LEBELLE (*Garden*, 53 (1898), No. 1388, pp. 544-548, figs. 4; 54 (1898), No. 1399, pp. 200, 291; No. 1401, pp. 240, 241).—This is an extract from the twelfth volume of the *Bulletin de la Société d'Horticulture de Sarthe*, giving descriptions and classification of a large number of species and hybrids of clematis.

Hybrid Wichuraiana roses, W. A. MANDA (*Amer. Florist*, 14 (1898), No. 531, pp. 1, 2).—Several hybrids of the hardy Asiatic rose (*Rosa wichuraiana*) with garden and forcing-house roses are noticed. Some of these combined in a remarkable way the characteristic foliage and hardiness of the Asiatic rose with other characters of the garden and forcing roses.

Hybrids of *Rosa wichuraiana*, H. DAUTHENAY (*Rev. Hort.*, 70 (1898), No. 20, pp. 479, 480).—Notes on results obtained by American gardeners.

Shrubs for the seaside and their grouping, M. HOWATH and M. MUNTE (*Amer. Gard.*, 19 (1898), No. 194, pp. 635-637, figs. 2).—These are prize articles on shrubs for exposed locations near the sea. Diagrams give the arrangement of groups suggested.

New Hampshire fruit calendar for 1897, F. W. RANE (*New Hampshire Sta. Bul.* 48, pp. 130-138, figs. 4).—This is a report on the condition of various orchard and small fruits in 1897. The fruits of several varieties of apples, pears, and plums are figured.

Report of the horticultural department of the Royal Academy experiment station, 1897, ERIK LINDGREN (*K. Landt. Akad. Handl. Tidskr.*, 37 (1898), No. 3, pp. 133-147).

FORESTRY.

The bald cypress, F. ROTH (*U. S. Dept. Agr., Division of Forestry Circ. 19, pp. 21, fig. 1*).—The author presents in a condensed form the results of tests and investigations made on the physical and mechanical properties of the bald cypress, *Taxodium distichum*, one of the important timber trees of the Southern States.

The bald cypress, a name given this tree on account of the fact that it loses its foliage in winter, includes white, yellow, black, and red cypress, names which have been used for advertising or other purposes, and which have caused much confusion as to actual differences in the timber.

Notes are given on the range and manner of occurrence, character of growth, and age of trees. More than 90 per cent of the cypress occurs on elevations of less than 100 ft. above sea level, and large bodies of merchantable cypress are not known to occur at elevations above 500 ft. The present supply of cypress is estimated at 27,000,000,000 ft., board measure, distributed among the States of Louisiana, Florida, Alabama, South Carolina, Georgia, North Carolina, Arkansas, and Mississippi. The estimated annual cut is about 500,000,000 ft., the greater part of which is taken within 120 miles of New Orleans.

The method of cutting generally pursued is to girdle the trees the season prior to felling them. This appears to be of doubtful value, since it adds but little to the floating capacity of the logs and endangers the timber. If girdling is done in the spring or summer, or even in early fall, insects at once begin their work. Generally their attack is confined to the inner bark and surface of the wood, but in some cases a large borer of the Ambrosia beetle group bores straight into the wood and produces a sharply marked black stain.

Notes are given on the character of the wood and its physical and mechanical properties.

There is a disease of the cypress known as "pegginess," said to be due to a fungus. This disease usually begins at the broken stub of a limb and works downward. A cross section of an infected log looks as though a number of small pegs $\frac{1}{4}$ to 1 in. in diameter had been driven into the wood and then withdrawn, the holes being filled with powdery decayed wood. Young trees are generally free from this trouble, and in no case was it seen in trees except where part of the crown had been broken off. The total loss due to this cause is probably not less than 30 per cent of the entire cypress supply. No region or locality seems to be entirely free from this defect, although places exist here and there that are especially infested. It is usually impossible to tell diseased from sound trees prior to felling them, but the common belief that the disease spreads after the timber is converted into lumber is not founded on fact.

In conclusion the author states that "the supply of cypress is considerable and the output capable of considerable increase, but once gone the present forests will be unable to replace the supply, and it is doubtful whether cypress can be considered as a timber of the future."

Increasing the durability of timber, B. E. FERNOW (*U. S. Dept. Agr., Division of Forestry Circ. 20, pp. 5*).—Popular information is given as to the cause and conditions of decay of wood. The manner in which timber is used and the actual factors influencing durability are pointed out. Lists of the more durable and less durable trees are given for the different parts of the country. The more durable trees of the eastern range are the red and white cedars; arborvitæ; bald cypress; tamarack; long leaf. Cuban, loblolly, short leaf. pitch, white, red, and jack pines; hemlock; spruce; live oak; white oaks, including white, post, bur, cow, and overcup; osage orange; red mulberry; black locust; catalpa; black walnut; chestnut; sweet (red) gum, and tulip. The less durable trees of this region are the elm, ash, red oak, and basswood. Trees not durable are hickory, maple, beech, blue beech, and birch.

The more durable trees of the Rocky Mountain region are the red cedar, piñon, foxtail pine, Douglas spruce, and western larch.

On the Pacific slope the more durable trees are the yew, redwood, Pacific arborvitæ, yellow cedar, Port Orford cedar, cañon live oak, and Pacific post oak.

The time of felling as influencing the durability of wood is mentioned, and treatment of timber after felling is considered at some length. The use of coatings to keep out moisture and preserve wood is discussed and the advantages of different preparations pointed out.

Forestry experiments at the Mustiala experiment station, 1894-95, T. CANNELIN (*Laud. Styr., Meddel., 1897, No. 20, pp. 58-72*).—The influence of forests on the temperature of the ground was studied, soil temperatures being taken daily in 3 different places, in a (1) 140-year-old pine forest, moist and sandy ground, (2) a small opening, 300 meters from the preceding place, and (3) a grove of birch, spruce, and pine, the ground drier than the other 2 places, and removed about 300 meters from the second. The temperature was taken at depths of 2, 1, and 0.5 meters in case of 2 and 3, and at 2 and 0.5 meters in case of 1. The summary figures for the different months of the year are given below.

Summary of soil temperatures at different depths.

Month.	Pine forest.		Opening.			Birch grove.		
	2 meters.	0.5 meter.	2 meters.	1 meter.	0.5 meter.	2 meters.	1 meter.	0.5 meter.

Studies in forestry, L. PETRINI (*Atti R. Accad. Econ. Agr. Geogr. Firenze, 4. ser., 20 (1897), No. 3-4, pp. 275-306*).

Technical and economic studies in forest culture, L. GALLONI (*Atti R. Accad. Econ. Agr. Geogr. Firenze, 4. ser., 20 (1897), No. 3-4, pp. 307-302*).

Some notes on the life history of forest trees, A. HEIMERL (*Wiener Illus. Gart. Ztg., 1898, No. 3, pp. 95-110, figs. 2*).

On forest culture, M. A. GRUDE (*Om Skookultur, Christiania, Norway, 1898, pp. 240*).

Tree planting on public streets, C. M. LORING (*Amer. Florist, 14 (1898), No. 532, p. 48*).—Suggests trees adapted to the purpose.

Tree planting in desert wastes (*Producers' Gaz. and Settlers' Rec. [West. Australia], 5 (1898), No. 3, p. 213*).—The author recommends the planting of *Acacia arabica* in the desert portions of Australia. The economic uses to which the tree is put are mentioned.

Our woods and forests, A. C. FORBES (*Gard. Chron., 3. ser., 24 (1898), No. 610, pp. 176, 177; 612, p. 213*).—Notes are given on some of the more interesting facts concerning the Crown woodlands of Great Britain.

The plane tree (*Gard. Chron., 3. ser., 24 (1898), No. 611, p. 190*).—Notes are given on *Platanus orientalis* and its value as a decorative tree. Several varieties of this species are briefly described and their relative merits given.

Report of the Commissioner of Forestry, J. T. ROTHROCK (*Pennsylvania Dept. Agr. Bul. 34, pp. 91-107*).—The author describes the present forest conditions of the State and the relation between rainfall, water flow, and forests. Figures are given showing the diminished flow during the autumn months of the Schuylkill River at Philadelphia, in which it appears that between 1816 and 1895 there was a depreciation of more than 60 per cent in the water flow of the stream.

Forest protection against tidal waves, S. HONDA (*Col. Agr. [Tokyo], Bul. 3 (1898), No. 4, pp. 281-298, pls. 2*).—An account is given of the value of forests as a means of protection against tidal waves or floods.

Practical assistance to farmers, lumbermen, and others in handling forest lands, G. PINCHOT (*U. S. Dept. Agr., Division of Forestry Circ. 21, pp. 5*).—This circular shows some of the practical results of proper handling of forests and states the conditions on which the Government will cooperate with forest owners. Tracts of any size from 5 acres up are eligible, the only distinction made being that the owners of large tracts which may present more difficult questions will be required to share in the expense of solving them, while owners of small tracts will receive assistance without expense. Two forms of agreement are given and applications can be made at any time.

DISEASES OF PLANTS.

Report of the botanist, B. D. HALSTED (*New Jersey Stas. Rpt. 1897, pp. 263-344, 355-391, figs. 45*).—The chief lines of work reported upon are with fungicides on various vegetables and ornamental plants, prevention of the sweet-potato soil rot, pear fire blight, peach-root gall, and the diseases of violets. The work with weeds has been continued and an experiment made to ascertain their influence on crop and soil.

Experiments with turnips (pp. 265-274).—The author has continued the investigations on club root (E. S. R., 9, p. 654). In the experiments in 1897 soil treatments of lime, sulphur, corrosive sublimate, kainit, copper sulphate, and Bordeaux mixture were given, but of these only the lime treatment gave satisfactory results, and this has proved almost

a specific for the prevention of club root. A second crop of turnips was sown on the ground after the removal of the first and the lime in this case gave much better results than in the first crop. The susceptibility of different varieties of turnips to club root was investigated to some extent. Other things being equal, the variety which is most superficial in its growth in the soil may be the least susceptible to club root. A limited experiment with buckwheat on turnip land was thought to indicate that buckwheat would exert a wholesome influence on a soil that is "turnip sick" from the presence of the club-root fungus. The effect of shading on the development of the club-root fungus was tested, and it was found that the growth of the fungus was as active in shaded as in exposed soils. Experiments were also conducted with 31 varieties of crucifers and 21 other plants representing 12 different genera, and it was found that while there is a large group of wild and cultivated crucifers that are susceptible to club root, many others are only occasionally attacked and may be grown on badly infected soil without being seriously injured. Of the plants representing other genera than crucifers no indication of club root was detected in any species.

Experiments with cabbages (pp. 275, 276).—Cabbages were sown on soil which had become so badly infected with club-root fungus that turnips in 1896 were almost all diseased. The cabbage seed was sown in a portion of this infected soil and at the time of setting out check plants that had been started in limed soil were planted for comparison. The details of the experiments are given, showing that the probable time when the plants are most susceptible is when they are quite small, and if this period can be passed free from exposure to the germs of the disease the crop may be almost sure.

Experiments with potatoes (pp. 276-281).—For the past 4 years one portion of the experiment station area has been devoted to the growth of potatoes to investigate the means for the prevention of potato scab (E. S. R., 9, p. 57). In 1897 the experiments of the previous years were modified somewhat. Oxalic acid, Bordeaux mixture, sulphur, kainit, sulphuric acid, and corrosive sublimate were employed as fungicides, and the effect of growing large-rooted weeds and sweet potatoes on the development of the disease was tested. The yields of the different plats are given, and so far as checking scab is concerned sulphur was the most efficient. The season was particularly adapted to the development of the potato rot due to *Phytophthora infestans*. The worst specimens of this disease were found on the shaded portion of the plat, although the plants in this area were somewhat later in being attacked.

Experiments with peppers (pp. 284, 285).—In continuation of previous experiments with peppers, 9 varieties were tested during 1897; and while disease was almost entirely absent throughout the season the experiment seems to indicate that in general pepper plants are too little infested with fungi to warrant the application of fungicides.

Experiments with tomatoes (pp. 286-291).—In 1897, 7 varieties of tomatoes were sprayed with Bordeaux mixture, soda-Bordeaux, potash-Bordeaux, and hydrate, the idea being to test the fungicides for the prevention of the various diseases to which this plant is subject. The only disease observed to affect the foliage of tomato plants was *Septoria lycopersici*, while a few fruits were attacked by *Glaosporium phomoides*. The plants which had received Bordeaux mixture were practically free from disease. The yield of fruit is tabulated, from which it appears that there was a marked falling off in the amount of fruits produced by the plants sprayed with soda-Bordeaux and hydrate. Both fungicides burned the foliage somewhat, but it was not thought sufficient to do serious harm. The least productive portion of the plot was that which was shaded; while, on the other hand, the shaded rows suffered very little from the blight.

Experiments with Lima beans (pp. 292-299).—Experiments conducted with dwarf Lima beans showed there was very little blight in any part of the plot, and no conclusions could be drawn from the experiments. The origin of the dwarf Limas and their description are given. Brief notes are appended on the mildew of Lima beans, in which it is stated that the mildew was worst on plants growing upon rich low land where the same crop had been grown the previous year. It would seem best for Lima beans to be planted on high ground, as early as possible, and they should not immediately follow a similar crop.

Experiments with onions (pp. 300-302).—The author reports the occurrence during 1897 of the smut fungus of onions (*Urocystis cepulae*). From observations made in the field it would seem that there are marked differences in the susceptibility of varieties to this disease, the tender white sorts being more inclined to the disease than the yellow ones. Experiments conducted with onions in new fields, the plants having been sprayed 6 times, showed that there was very little smut anywhere, even the check rows being free from the disease. An experiment in preventing infection through the seed was made with seed soaked in hot water (135° F.) for 15 minutes, soaked in corrosive sublimate, or rolled in sulphur, and in adding corrosive sublimate and sulphur to the soil. The plants came up fairly well in all boxes except where the seed was treated with hot water, in which case there was a complete failure. There was no smut in any instance; the experiment, therefore, was without result.

Results with spinach (pp. 302, 303).—Experiments were conducted with a number of varieties of spinach for the prevention of an undetermined disease which causes a loss of the green color and the final dwarfing of the young plants. The plants grown in the shade were larger and remained green longer than those exposed to the sun, and it is probable this crop can be grown throughout the season with profit where some protection, as partial shade, is provided. Notes are given on the occurrence of a *Cercospora* on the leaves of spinach,

closely resembling that occurring on beet leaves. There appears to be some difference in the characteristics of the two, but the variations are thought to be within the limits of a species, and their probable identity is pointed out.

Experiments with eggplants (pp. 304-307).—Four varieties of eggplants were sprayed with different fungicides for the prevention of attacks of *Phyllosticta hortorum*. There was but little difference noted in the effectiveness of the 4 fungicides used. An examination of many of the roots at harvest time showed they were badly infested with nematodes, in some places the galls being very apparent.

Experiments with lettuce (pp. 307-309).—Sprayings were made with 4 fungicides on different varieties of lettuce, for the prevention of blight, and it was found that the early sprayings of all the plants somewhat injured them. There was very little blight present until the plants had passed blooming. On this account there was no estimate made of the amount of damage or of the efficiency of the fungicides.

Experiments with beans (pp. 309-314).—Experiments were conducted during 1897 with beans on soil that had grown 7 or 8 successive crops, the object being to test means for the prevention of pod spot and bacterial blight, both of which have existed to some extent since 1894. No appreciable amount of blight was present and in many cases the application of the fungicides to the young plants had an injurious effect. A second crop was planted July 31 and treated with fungicides the same as before. There was no marked difference in the action of the different fungicides, but the potash-Bordeaux mixture was slightly better than the others. The effect of thinning pods as a means of preventing disease was investigated and found to be without any appreciable value.

Crimson clover disease (pp. 314-319).—Notes are given of a crown disease of crimson clover, due to *Sclerotinia trifoliorum*. Desiring to study the fungus in the field, a plat was sowed with different kinds of clover and allied plants, the ground being strewn with the debris of dead plants and adhering soil after the seed was sown. Of all the clovers tested, the crimson clover proved most susceptible to the disease. The author states that there is nothing to indicate that the disease may be transmitted by seed, but that a field once badly infected should be plowed and planted to other crops for a number of years. The occurrence of another fungus, *Polythrincium trifolii*, on scarlet clover, is mentioned.

Experiments with cucumbers (pp. 319-322).—Eight applications of 4 different kinds of fungicides were made on a number of varieties of cucumbers, to test their efficiency in preventing mildew and anthracnose. The anthracnose was not noticed on any of the plants during the year. The other disease became quite abundant in September, the plants sprayed with Bordeaux mixture and potash-Bordeaux being less affected than the others. An attempt was made to inoculate cucumbers with an anthracnose of hops due to *Colletotrichum* sp., without success.

Experiments with peas (pp. 322-324).—In continuation of the experiments reported in 1896 (E. S. R., 9, p. 656), applications to the soil of sulphur, corrosive sublimate, carbonate of lime, and copper sulphate were tested for the prevention of blight and mildew of this plant. The largest yield was obtained where the soil was treated with corrosive sublimate and carbonate of lime. On a second crop, 4 fungicides were tested with somewhat inconclusive results.

Experiments with carrots (pp. 325, 326).—Six varieties of carrots were tested to ascertain their relative resistance to blight. No spraying was given the plants and no estimate was made to determine the relative market value of the different sorts. Of the 6 varieties tested the Danvers Half Long proved the most resistant.

Experiments with celery (p. 327).—The carrots mentioned in the previous paragraph were followed by celery, the desire being to ascertain whether these allied plants would be subject to the same diseases. The celery was sprayed with different fungicides, in all 7 applications being given, but the plants being remarkably free from celery blight the relative value of the fungicides was not determined.

Experiments with beets (pp. 327-334).—Experiments have been continued for a number of seasons for the control by the use of fungicides of beet-leaf spot (*Cercospora beticola*). The seed was sown April 19 and the plants were sprayed when little more than the first leaves were developed, in all 10 applications being given during the season. The leaf spot was first noted the last week in June and in the check plats it increased rapidly. Where the hydrate solution was used the disease developed somewhat slower than in the checks, but plants sprayed with this fungicide suffered much more severely than those which received the different Bordeaux solutions. The different kinds of Bordeaux mixture showed no marked differences. In the experiments with the second crop of beets, all the fungicides except Bordeaux mixture burned the foliage of the young plants to some extent, but as in the previous year's test no *Cercospora* appeared. The effect of weed growth on beet production was tested. In this experiment 8 oz. of 30 different kinds of weed seeds were sown over a plat of beets 138 ft. long and 11 ft. wide. Different portions of the plat were subjected to different treatments, one receiving no cultural attention while the others received 3, 5, and 7 hoeings, respectively. The yield of beets was almost in proportion to the amount of attention given the plats. Concerning the growth of the weeds it is said that in some cases the ground was so thoroughly covered by them that many of the weeds were wilted and crowded out.

Experiments with ornamental plants (pp. 334-339).—Fungicides were tested for the prevention of diseases of the following plants: Violets, China asters, pinks, nasturtiums, mignonette, phlox, sweet peas, gladiolus, cannas, dahlias, ampelopsis, hibiscus, hollyhocks, red bud, and peony. In the case of the China asters the principal trouble is a rust due to *Coleosporium* sp. The disease did not appear to any great extent

but the plants were injured by insects so that their growth was seriously interfered with, therefore no report could be made of the value of the spraying. The fungicides seemed to have no effect on nasturtium blight, and scarcely adhered at all to the leaves. The experiment with sweet peas tested not only the effect of fungicides but also the effect of different depths of planting. The largest number of flowers were obtained where the seeds were planted 3 in. deep and hilled up 2 in. Where seeds were first soaked in Bordeaux mixture, rolled in sulphur and corrosive sublimate, and planted 2 in. deep, all gave good results. The canna plants were free from fungus diseases, but the foliage of some plants was injured by the application of soda-Bordeaux and hydrate. The mildew of dabbias appeared abundantly on unsprayed sections during the autumn but it was easily checked by the use of fungicides. Hollyhocks sprayed with different Bordeaux mixtures, receiving in all 13 sprayings, were almost entirely free from the leaf spot which appeared on the check plats early in the season and continued until its close. The hollyhock rust (*Puccinia malvacearum*) was found almost without exception on check plants, while but one sprayed section showed any disease. The sprayed peony plants bloomed much less abundantly than the unsprayed plants and no disease was observed on any.

Experiments with fungicides (pp. 330-344).—The author gives the formulas and methods of preparation of the fungicides used in the preceding experiments, namely, Bordeaux mixture, soda-Bordeaux, potash-Bordeaux, and cupric hydrate.

Experiments in infecting soil with potato-scab fungus (pp. 355-359).—Experiments are reported in which scabby potatoes were (1) spaded into the soil; (2) steamed 20 minutes and then spaded in; (3) applied to the surface of the soil and allowed to remain over winter, and (4) fed to stock and the manure applied to the soil. The results are tabulated and the following conclusions drawn:

Scab was greatest where the untreated potatoes were spaded in in September, followed closely by the case in which steamed potatoes were spaded in. The plats which received manure gave results which indicated a very limited presence of the scab fungus. While the experiment was somewhat limited, it was interesting to notice the almost entire absence of scab where the infested potatoes were fed to cattle and the manure placed on the land. This seems to indicate that there is little danger in disposing of scabby potatoes in this manner.

An additional experiment is reported in which a number of solanaceous plants, together with a miscellaneous lot, were tested to ascertain their susceptibility to the scab fungus. Of the solanaceous plants, only the roots of tomato, pepper, tobacco, and *Datura stramonium* showed any evidence of the fungus. Sweet potatoes gave no indications of the disease. Artichokes, cardoon, chicory, salsify, parsnips, and 6 varieties of radishes were tested, and while all the varieties of radish were more or less disfigured by scab, the other plants remained free.

The influence of drought on vegetation (pp. 360-362).—The year 1897 is said to have been remarkable for excessive rains in July and for 3 periods of drought during the growing season, the influence of which on vegetables and ornamental plants is stated.

Experiments with sweet potatoes (pp. 362-372).—In continuation of work reported on sweet-potato diseases (E. S. R., 9, p. 655), the effects of sulphur and kainit were again tested, different plats receiving 800, 600, 400, 300, and 200 lbs. of the fertilizer. Two varieties of sweet potatoes were used, Nansmond and Jersey Red. The results indicate that sulphur is valuable as a remedy for the prevention of the soil rot, and that it may be advantageously used in connection with kainit.

Experiments in spraying for asparagus rust (pp. 372-376).—The extensive experiments with fungicides showed that while they did not prevent the disease they reduced it fully one-fourth.

Experiments with pear blight (pp. 377-383).—The author reports upon a series of experiments begun on an orchard placed at the disposal of the station, the present report being confined to the effect of winter and summer pruning. In general it may be stated that while the winter-pruned trees were cut back the heaviest the pears were much larger and yielded about as great a quantity as the summer-pruned ones, the difference between the 2 forms being very slight. The experiments testing the effect of cultivation and the use of fertilizers on the development of blight are to be continued.

Greenhouse experiments with violets (pp. 383-394).—The leading fungus diseases of the violet are said to be the leaf spots (*Cercospora viola*), a second form of leaf spot (*Phyllosticta viola*), *Ascochyta viola*, *Marsonia viola*, *Glauosporium viola*, an anthracnose due to an undescribed *Colletotrichum*, a mildew (*Peronospora viola*), and *Zygodessmus albidus*. In addition to these nematodes are one of the most serious troubles of violets. During the winter of 1896-97, experiments were conducted in the greenhouse in which the effect of depth of soil, fineness of mixture, drainage, mulching, watering, subirrigation, fertilizers, manure, aeration, spraying, and soil fungicides were tested. A depth of soil of 5 in. seemed to give best results. The coarsest soil, i. e., that which did not go through a sieve with a half-inch mesh, gave best results. Where sand was added in different quantities to fine soil but little difference was noted. The experiment in soil drainage seemed to indicate that the use of rock bottom for drainage is useless. Increasing the amount of manure was followed by beneficial results. There was no leaf spot or other foliage disease which seemed to interfere with the growth of the plants, but attacks of nematodes were very apparent, many of the plants being badly galled.

Field experiments were conducted with violets in which soil treatment with lime, sulphur, corrosive sublimate, and kainit were tested, the intention being to note the results of this soil treatment on the winter plants. All the treatments greatly reduced the formation of nematode galls on the roots, and in many cases wholly prevented them.

Some important pear diseases, B. M. DUGGAR (*New York Cornell Sta. Bul. 115, pp. 596-627, figs. 16, dgm. 1*).—Notes are given on pear-leaf spot, leaf blight, pear scab, and pear blight.

The leaf spot due to *Septoria piricola* is said to be widely distributed throughout the State, and while the fungus is one of the most important from an economic standpoint, it seems to have been almost wholly overlooked or neglected. Perhaps one of the earliest mentions of this disease was that by G. F. Atkinson.¹ It is usually confused with the ordinary leaf blight, due to *Eutomosporium maculatum*. The leaf spot, as it appears on the green leaves, is usually larger, more sharply defined, and somewhat angular, being roughly limited by the subdivisions of the venation. The center of the spots is grayish-white, dotted with minute pycnidia. Surrounding this is a brown zone, which frequently shades off into a purplish color. The cluster of fruiting bodies in the center of the spot is a very evident characteristic.

The author reports the disease as probably occurring all over the State of New York wherever pears are raised, and also in Pennsylvania, Maryland, Virginia, Alabama, and elsewhere. His investigations seem to indicate that different varieties are subject to the disease in varying degree. Anjou, Seckel, Bosc, Summer Doyenne, and Bartlett are quite subject; Louise Bonne, Clairgeau, Clapp Favorite, Flemish Beauty, and others to a less extent; Duchess very slightly, and Kieffer and Winter Nellis are apparently free from it.

An experiment was conducted in which Bordeaux mixture, ammoniacal copper carbonate, and potassium sulphid solution were sprayed on Bartlett and Seckel trees for the prevention of leaf spots. Three sprayings of Bordeaux mixture gave almost complete protection against the disease. The occurrence of leaf spot on nursery stock has also been investigated, and some attempts have been made to prevent injury. In this case, as in the trial in the orchard, Bordeaux mixture gave the best results. The microscopic characters of the fungus are given at some length. The author states that the fungus is evidently to be referred to *Septoria piricola*. He has compared American specimens with specimens from Europe and found that they agree in almost every particular.

The leaf blight of pears has also been studied in connection with the leaf spot, and the author states that the spots of the leaf blight are usually smaller than those of the leaf spot, are more nearly circular, and not so clearly defined on the under surface. On the fruit the spots of leaf blight are red at first, but soon become darker. The drying of the epidermal cells may cause cracking to a considerable extent, as in the case of the pear scab. The leaf-spot fungus in no case attacks the fruit. The microscopic characters, distribution, and remedies of leaf blight are given.

¹Garden and Forest, 10 (1897), p. 373.

The pear scab (*Fusicladium pirinum*) is figured and described at some length. The author states that his investigations on the pear fruit have shown that the principal stroma of the fungus is undoubtedly subepidermal. The fungus is said to pass the winter in the bark of twigs, producing in the spring a crop of spores to infect the young branches, leaves, and fruit. A winter stage of the fungus is reported from Germany as belonging to the genus *Venturia*. The possible identity of the pear and apple scab is briefly considered, but most of the recent work is said to show that the two fungi are specifically different. As is the case with other pear diseases, there is considerable difference in the susceptibility of the different varieties. Three applications of Bordeaux mixture, the first made just before blossoming, the second immediately after the petals have fallen, and the third about 2 weeks later, are generally sufficient to prevent attacks of this fungus.

The pear blight or fire blight, which is due to *Bacillus amyglororus*, is figured and described at considerable length, the conclusions of the author agreeing with those expressed by B. M. Waite (*E. S. R.*, 8, p. 796).

Under each of the diseases described the author gives a brief bibliography.

Studies on bean anthracnose, E. GAIN (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 3, pp. 200-201).—The author has made a study of the anthracnose of beans due to the fungus *Colletotrichum lindemuthianum*, paying particular attention to the effect the fungus produces upon the seed. He reports that anthracnosed seeds are less dense than sound ones, the difference amounting with one variety to from 3.4 to 4.8 per cent and in others as much as 8 per cent. The germinative ability of diseased seed was also studied, and it was found in a series of experiments that 10 per cent of the seeds did not germinate, while only 46 per cent made viable plants, the sound seed producing 98 per cent.

Experiments were conducted in the laboratory and in the field to test the propagation of the disease by seed and other means, and it was found that it spread quite easily from diseased seed, the presence of spores placed on a seed or in the soil.

The conclusions, briefly summarized, show that diseased seeds are easily recognized by their lessened specific gravity and lower germinating power. Plants from diseased seed are less resistant to subsequent attacks and seldom develop equal to those from sound seed. The distribution of the disease is easily effected through the soil or seed. The author recommends that seed be carefully hand-selected before planting and the lighter seed thrown out.

A cure for the lily disease, H. BYATT (*Gard. Chron.*, 3, ser., 24 (1898), No. 603, p. 42).—The author gives an account of his attempts to prevent the occurrence of this disease on *Lilium candidum*. The method of treatment, which he claims has proved successful, consists in removing the bulbs from the ground and, after they had dried, sprinkling

them well with flowers of sulphur and putting them in large paper bags. They are then well shaken until the sulphur has worked into the bulbs thoroughly, and while still covered with the powder are planted. This treatment was first tried in 1896, and the crop produced showed a marked improvement in the flowers, the plants seeming to be entirely free from disease.

Septoria graminum, a parasite of wheat, L. MANGIN (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 20, pp. 1138-1140).—The author calls attention to the parasitism of this fungus, it being sometimes considered a saprophyte, and shows that under certain conditions of weather it undoubtedly becomes parasitic on the leaves of winter wheat. He states that a mild and rainy winter favors the extension of the parasite, and reports having found it abundant on the leaves in February, the pycnidia carrying spores in an advanced state of germination. Reports are given of inoculation experiments made in February, March, and April, in which the spores were placed on the leaves and the leaves kept damp either by means of contact with filter paper or under bell jars. In about seven days all the leaves which had been treated began to turn yellow, and a week later their tips became blanched and in the dead tissues the characteristic pycnidia of the fungus made its appearance. The author considers the parasitism of *Septoria graminum* established, and states that the damage done by the fungus can be easily seen in fields of winter wheat in the spring, the diseased leaves being smaller and of a different color than normal.

Wood ashes and apple scab, S. A. BEACH (*New York State Sta. Bul.* 140, pp. 665-680).—The author reports an experiment continued for 5 years in which liberal applications of hard-woodashes were given 124 trees to test the effect of such treatment on the prevalence of apple scab, the theory being that the application of the ashes would induce a much more vigorous growth of the tree and so render it resistant to disease. The treated sections of the orchard showed in many cases an improved appearance of foliage, but there was no evidence of an increase in immunity from the disease. The author concludes that under the conditions of the investigation a liberal application of hard-wood ashes to the soil does not increase the immunity of apples from apple scab.

The communicability of potato-stem blight, F. C. STEWART (*New York State Sta. Bul.* 138, pp. 632-631).—The author conducted experiments to ascertain if possible the communicability of the potato-stem blight described by him (*E. S. R.*, 8, p. 235). So far as his investigations go, the disease is not due to bacteria or fungi, but appears in all probability to be due to some impairment of the physiological functions of the plant. The results of the experiments give strong evidence that the disease is not communicable. Although they show that a fair yield of healthy tubers may be obtained from diseased seed, the planting of such seed is not recommended.

Attempts were made to inoculate the disease upon other closely related plants but without success.

The effect of plowing under green rye to prevent potato scab, F. C. STEWART (*New York State Sta. Bul.* 138, pp. 629-631).—The widespread notion that potatoes will be free from scab if grown on soil on which green rye has been plowed under just before planting was investigated by the author. The land used for the experiment was fairly uniform and in 1896 had grown a crop of potatoes which was so scabby that a large part of the crop was unmerchantable. Rye was sown on 3 alternating plats October 12 and was plowed under April 26, being at that time about 6 in. high. The plats were planted April 28 and half of all the seed tubers were soaked in corrosive sublimate before planting. The yield of the various plats is tabulated, and it appears that the total yield as well as the proportion of those free from scab was less on the plats where green rye had been turned under than on the others, while the unmerchantable tubers were considerably in excess on these plats. The conclusion drawn from this experiment is that the practice of plowing under green rye to prevent potato scab is not to be recommended, inasmuch as it tends to increase rather than diminish the amount of scab and may also reduce the yield. The large amount of scab on all the plats showed the uselessness of treating seed with fungicides when they are to be planted in soil known to be scab-infested.

Department of bacteriology, H. H. LAMSON (*New Hampshire Sta. Bul.* 48, pp. 116, 117).—A report is given of work carried on during the year, partly in continuation of work previously reported (E. S. R., 9, p. 763). Brief notes are given on leaf spot of apples, orange rust of quinces, and black knot of plums and cherries. For the leaf spot, due to *Phyllosticta pirini*, applications of Bordeaux mixture seem to have had but little effect. The orange rust of quince trees was also but little affected by the treatment, and the results of experiments conducted with Bordeaux mixture for the prevention of black knot will not be apparent until the season succeeding the application of the fungicide.

A brief report is made on the use of Ceres-pulver for the prevention of smut of oats and barley. But little smut occurred in any of the grain, but the author thinks there was slightly less where the seed was treated than in the other lots.

Experiments with potato scab in which the effects of different fertilizers were tested were continued, as well as experiments for the prevention of early and late blight.

An experiment was undertaken with Nitragin, but the culture was too old when used and the trial was made on so small a scale that no conclusions can be drawn.

Effects of common salt on the growth of carnations and carnation rust, F. C. STEWART (*New York State Sta. Bul.* 138, pp. 631-636).—Some florists having advocated the use of a solution of salt in the form of a fine spray on the foliage of carnations, believing that it prevented the attacks of rust (*Uromyces caryophyllinus*) and also gave the plants more vigor, the author conducted a series of experiments with 50 rooted cuttings which were potted in 6 in. pots, sunk in soil

out of doors. They were divided into different lots and treated at intervals of 2 weeks with different quantities of a 2½ per cent salt solution, the different lots receiving during the investigation 10, 40, 80, and 200 cc. of a salt solution. In 1897 this experiment was repeated, the dates of application of the salt solution being May 18, 28, June 11, 25, July 9, 23, August 7, 20, and September 3. Both the experiments show that it was useless to try to prevent the rust by the use of salt solutions, either applied to the soil or on the foliage, and that such applications of salt did not aid in the growth of carnations.

Further experiments on spraying cucumbers, F. C. STEWART (*New York State Sta. Bul. 138, pp. 636-644*).—Experiments reported on the effect of spraying late cucumbers (*E. S. R., 9, p. 248*) were continued with early cucumbers. Eight rows of 25 hills each were planted early in May, and 4 of the 8 rows were kept well covered with Bordeaux mixture throughout the season, 14 applications being given the plants. The weather was rather unfavorable for the growth of cucumbers, yet they did fairly well. The first disease to make its appearance was the bacterial wilt disease, which appeared about August 2, and during the following 2 weeks killed about 50 plants on the unsprayed plat and only 5 or 6 on the sprayed. On August 11 there were traces of anthracnose on the unsprayed plat, and toward the end of the season it was very destructive. It also did some damage on the sprayed plat toward the close of the season. The downy mildew appeared about the same time on the unsprayed plat, where it spread rapidly and did much damage, but did not attack plants on the sprayed plat. A careful record was made of the number and weight of the fruits of the different plats and the increase in number of fruits and weights due to the spraying as shown. In general it is stated that on Long Island it is unnecessary to begin spraying cucumbers until the middle of July. The downy mildew is easier to control by spraying than the anthracnose. The prevalence and destructiveness of the downy mildew of the cucumber on Long Island during 1896 is noted, and it is shown that it was more destructive that year than the year following. A relation between the appearance of this disease and the rainfall has been claimed, but the author states that probably the high temperature the first year had more effect than the rainfall.

For the purpose of ascertaining to what extent the downy mildew can be controlled when an entire field of cucumbers is sprayed, a cooperative experiment was conducted in which an acre planted to cucumbers was sprayed 8 times with Bordeaux mixture 1 to 8 formula. The dates of spraying were July 22, 30, August 7, 16, 25, September 4, 13, 20. The experiment was terminated by a killing frost on the night of September 28. The total yield of fruits is given, showing that the production was slightly in excess of 100,000 for an acre, the average yield on Long Island in 1897 being about 20,000 per acre.

The common observation that downy mildew is less destructive to cucumber plants when partly shaded led to an experiment in which

sweet corn was alternately planted with rows of cucumbers. The unshaded plants made considerably better growth than the shaded ones, and there was no appreciable difference in the amount of anthracnose and only a slight difference in the amount of downy mildew. Consequently it seems improbable that shading can be advantageously employed as a preventive of downy mildew.

The author reports the presence of the downy mildew (*Plasmopara cubensis*) on the winter crook-neck squash (*Cucumis moschata*), this being a new host plant for the fungus.

Suggestions on spraying, H. P. GOULD (*New York Cornell Sta. Bul.* 141, pp. 579-586).—Some notes on spraying are given to supplement the information contained in previous bulletins of the station. The summary is as follows:

"Many of the recently introduced insecticides and fungicides are no better than some of the older and better known materials, and they are sometimes inferior to them. Arsenite of lime prepared according to the directions of Dr. Kedzie seems to be the best substitute for Paris green. Powdered Bordeaux mixture has not given good satisfaction with us. Certain modifications of Bordeaux as proposed by Halsted may possess some advantages over the common formula for special purposes. In spraying for insect foes, the kind of material used must be governed by the feeding habits of insects for which the treatment is made. Bordeaux mixture seems to lessen the ravages of the striped cucumber beetle, as also the flea-beetle. Thoroughness in spraying is one of the most important elements of success and one often disregarded. Spray at the proper time. Under no conditions spray with poisons when fruit trees are in full bloom."

On the present status of the cereal rust question, J. ERIKSSON (*Ber. Deut. Bot. Gesell.*, 15 (1897), pp. 183-194; *abs. in Ztschr. Pflanzenkrank.*, 8 (1898), No. 3, pp. 168, 169).—The substance of this article has already appeared (*E. S. R.*, 10, p. 316).

Recent observations of Eriksson on the rusts of cereals, C. B. FLOWRIGHT (*Gard. Chron.*, 3. ser., 24 (1898), No. 615, pp. 269, 270).—Paper read before the British Mycological Society, September 19, 1898.

The asparagus rust, F. A. WAUGH (*Gard. Chron.*, 3. ser., 24 (1898), No. 607, p. 120).—A brief account is given of *Puccinia asparagi* in the eastern United States.

Fungus diseases of hollyhocks, B. D. HALSTED (*Amer. Florist*, 13 (1898), No. 523, pp. 1342, 1343, fig. 1).—Brief notes are given of *Cercospora althæina*, *Phyllosticta althæina*, *Colletotrichum althæa*, and *Puccinia malvacearum*.

Chrysanthemum rust, B. D. HALSTED (*Amer. Florist*, 13 (1898), No. 522, p. 1312, fig. 1).—This disease is popularly described, and a warning against it is given to all growers.

Chrysanthemum rust, G. MASSEE (*Gard. Chron.*, 3. ser., 24 (1898), No. 615, p. 269, fig. 1).—Notes are given of *Puccinia hieracii*, its occurrence and means for combating it. Reprinted in *Amer. Gard.*, 19 (1898), No. 200, p. 727.

Wood ashes not an apple scab preventive, F. H. HALL (*New York State Sta. Bul.* 140, popular ed., pp. 6).—This is a popular summary of Bulletin 110 (see p. 452).

Experiments for preventing potato scab, TEICHERT (*Ztschr. Spiritusind.*, 1898, No. 13, p. 119).

Experiments in infecting soil with potato-scab fungus, B. D. HALSTED (*Amer. Gard.*, 19 (1898), No. 181, pp. 137, 136).—The experiments show the possibility of infecting soil with the fungus several months before planting the crop. The scabby tubers were applied directly and fed to stock and the manure applied with similar results.

Potato scab, R. HELMS (*Producers' Gaz. and Settlers' Rec.* [West. Australia], 5 (1898), No. 5, pp. 382-384).—Popular notes are given on the cause of potato scab and suggestions for its prevention.

One cause of the brown or black rot of cabbages, E. F. SMITH (*Ztschr. Pflanzenkrank.*, 8 (1898), No. 3, pp. 134-137, pl. 1).—The author summarizes the results of his investigations on the black rot of cabbages due to *Pseudomonas campestris*. More extended accounts of the investigations have been given in Farmers' Bulletin 68 (E. S. R., 9, p. 819) and in Centbl. Bakt. u. Par., 2, Abt., 3 (1897), p. 284 (E. S. R., 9, p. 817).

A bacterial disease of mulberries, D. MCALPINE (*Ztschr. Pflanzenkrank.*, 8 (1898), No. 3, pp. 141, 143).—The author briefly describes a bacterial disease of mulberry twigs which has appeared in various parts of Victoria, Australia, and states that the specific organism is probably that described by Boyer and Lambert as *Bacterium mori*.

Club root of cabbage, P. HENNINGS (*Ztschr. Pflanzenkrank.*, 8 (1898), No. 3, p. 124).—In a brief note the author states that the characteristic formations caused by *Plasmodiophora brassicae* have been found on the *Nasturtium palustre* and *Raphanus raphanistrum*.

Sorghum blight and the bacteria which cause it, F. F. BRUYNING (*Arch. Neerland. Sci. Exact. et Nat.*, 1898, No. 4-5).

Relation of temperature and growth of vine to black rot, G. CAZEAUX-CAZALET (*Rev. Vit.*, 1898, No. 217, pp. 173-179; 218, pp. 201-208; 219, pp. 229-233).

Root rot of coffee, F. NOACK (*Ztschr. Pflanzenkrank.*, 8 (1898), No. 3, pp. 137-142).—The author describes a root rot of coffee, which is said to be due to nematodes. They appear to attack most severely the taproot, and the plant dies within a few years, dependent upon the vigor of the tree. The author states that by early and repeated local applications of carbon bisulphid the injury may be reduced to a minimum.

The violet disease, B. D. HALSTED (*Amer. Florist*, 14 (1898), No. 541, p. 310).—Notes are given on *Cercospora violae* and *Phyllosticta viola*, with suggestions for preventing their attacks.

Leaf spot and fruit rot of tomatoes, B. D. HALSTED (*Amer. Gard.*, 19 (1898), No. 183, p. 468, figs. 2).—Notes are given of these diseases and methods followed for their prevention.

Phyllosticta hortorum on eggplants, B. D. HALSTED (*Amer. Gard.*, 19 (1898), No. 187, p. 531, fig. 1).

A palm-leaf blight, B. D. HALSTED (*Amer. Florist*, 13 (1898), No. 526, p. 1426, figs. 2).—Illustrated notes are given of a blight of *Livistonia rotundifolia* due to *Colletotrichum* sp.

Exobasidium vitis, A. POTEBNIA (*Arb. Naturforsch.-Gesell. Charkow*, 31 (1897), pp. 25-27, pl. 1; *abs. in Bot. Centbl.*, 75 (1898), No. 4-5, pp. 122, 123).

Concerning the destruction of barley by a new fungus parasite (*Separate from Wchnschr. Brau.*, 15 (1897), No. 42, pp. 2).

The Bermuda lily disease, G. A. BISHOP (*Florists' Exchange*, 10 (1898), No. 35, pp. 832, 833).—A summary is given of the report of the author concerning this disease. It is said to be due to the following causes: Heavy manuring with barnyard manure; repetition of crop on the same ground; reduced vitality; bad selection of stock, and insufficiency of plant food. All these render the plant subject to fungus attacks. Directions for soils and manures are given, and where the plants are attacked by fungi and insects, spraying is recommended, formulas being given.

The lily disease in Bermuda, A. L. KEAN (*New England Florist*, 4 (1898), No. 16, p. 183).—Popular notes on this disease.

Gumming of stone fruits, S. A. BEACH (*Amer. Gard.*, 19 (1898), No. 192, p. 606).—Compiled information on the cause of gumming of stone fruits.

Violet diseases, W. G. SALTFOED (*Amer. Gard.*, 19 (1898), No. 188, p. 547, fig. 1).—Suggests remedial treatment.

Concerning the cause of the "sereh" disease of sugar cane, a review of the investigations and theories of WAKKER, W. KRÜGER (*Dent. Zuckerind.*, 23 (1898), p. 225; *abs. in Centbl. Bakt. u. Par.*, 2, *Abt.*, 1 (1898), No. 12, pp. 524-526).

The influence of fertilizers on the diseases and injuries of the vine, P. COSTE-FLORET (*Influence des engrais sur les maladies et accidents de végétation de la vigne*, Montpellier: Hamelin frères, 1898, pp. 31).

The fungus foes of the farmer, B. D. HALSTED (*Pennsylvania Dept. Agr. Rpt.*, 1896, pp. 678-692, figs. 6).—The author figures and properly describes a number of the more common fungi which attack economic crops.

A review of the sugar-cane diseases of Java, II, I. ZEHNTNER (*Arch. Java. Suikerind.*, 1897, pt. 10, pp. 51; *abs. in Ztschr. Pflanzenkrankh.*, 8 (1898), No. 3, pp. 161-163).—This part of the author's work on the diseases and enemies of sugar cane deals wholly with those injuries caused by animals.

Work upon some diseases of plants in 1897, F. H. HALL (*New York State Sta. Bul.*, 138, popular ed., pp. 6).—A popular summary is given of the results published in Bulletin 138 of the station (see pp. 452-454).

Ear cockle in wheat, R. HELMS (*Producers' Gaz. and Settlers' Rec.* [West. Australia], 5 (1898), No. 4, pp. 280-283, figs. 2).—The author figures and describes the effect of a nematode attack on wheat, the result being large gall-like formations in place of the grain. As a possible means for the prevention of the destructive attacks of this parasite the fallowing of fields and the alternation of crops are recommended.

An albuminous Bordeaux mixture, CAZENEUVE (*Vigne Franc.*, 1898, No. 4, pp. 51-53).

Spraying for the destruction of fungi and insects, S. T. MAYNARD (*Massachusetts Hatch Sta. Bul.*, 52, pp. 15-19).—The author gives formulas for the preparation and directions for the use of Bordeaux mixture, dilute copper sulphate, and kerosene emulsion. A spray calendar is given in which the time of application and fungicide or insecticide required is mentioned for the prevention of fungus and insect attacks on different fruits and vegetables.

Preventive treatment in plant disease—hybridization and inoculation, H. TRYON (*Queensland Agr. Jour.*, 2 (1898), No. 6, pp. 511-516).—A discussion of inoculation for plant diseases and breeding resistant varieties.

ENTOMOLOGY.

Report of the entomologist, J. B. SMITH (*New Jersey Stas. Rpt.*, 1897, pp. 397-492, pls. 8, figs. 19).—In the general review beginning his report the author notes the following insects and their injuries during the year: The army worm and Hessian fly, both of which seem to have disappeared; the pear midge, which seems to be actually stamped out in certain localities; the sinuate pear borer, which is held in check; the wood leopard moth; the maple pseudo-coccus, which is present in small numbers; the harlequin cabbage bug, which seems to have been decidedly checked by the cold, wet spring, and early summer; tomato louse; strawberry-root louse, troublesome in 1896 but apparently absent in 1897; the San José scale, to which more time was given than to any other insect; cutworms; leaf rollers; strawberry weevils, locally injurious; white grubs, reported as strawberry pests but not as seriously

injurious; potato beetles, for which arsenate of lead is recommended; a tortoise beetle (*Coptocycla clarata*), a new pest reported from Deekertown in June, where it was eating off potato stalks; rose chafers, which seem to be on the increase; *Lecanium tulipifera*; root webworms; *Crioceris 12-punctata*; cabbage worms; sawflies; *Selandria carya*; bagworms; codling moths; plum cureulio; the round-headed apple-tree borer; pear-blister mite; pear slugs; fig eater (*Allothina nitida*); *Procris americana*; and *Momhammus tilillator*.

A study was made of Paris green as an insecticide. Samples were obtained from a large number of firms, and analyses made which showed that they ranged in arsenious oxid from 41.51 to 68.59 per cent. Variations were found even in different samples from the same manufacturer. Explanatory letters were received which, though not directly so stated, admitted the possibility of a variation of 15 per cent. This was not considered by the firm from which the letter came to be worth considering from a practical standpoint, but from this statement the author differs, stating that the "difference of even 10 per cent of arsenic may make all the difference between an effective and an ineffective application." From obtainable facts it appears that Paris green even under the best conditions varies greatly in the percentage of arsenic and that it may be present either as an arsenite or as an arsenate. Difficulties increase with the size of the quantities manufactured so that a difference of 25 per cent may exist in the absolutely unadulterated product. Hence it follows that the material as used by farmers is found to be unreliable and the results inconsistent. As an alternative the use of arsenate of lead is suggested. The formula given for it is 4 oz. arsenate of soda and 11 oz. acetate of lead dissolved separately and then mixed. The resulting solution is to be added to 100 gal. of water for most insects, to 80 gal. for more resistant insects, and to 50 gal. for potato beetles. This insecticide is strongly recommended.

Experiments were made with emulsion sprayers in which the emulsion was obtained by mechanical means, which developed considerable variation in the degree of reliability. The Success Emulsion Sprayer was found to be wholly unreliable with mixtures in the proportion of 1:20, which proportion was actually never obtained in the spray, the proportion ranging all the way from 1:100 to 1:15. Mixtures at the rate of 1:15 exhibited much less variation, the spray showing from 7.3 to 10.5 per cent of kerosene. At the rate of 1:10 and 2:10 the results were practically uniform.

Experiments were also made with kerosene, which are reported in considerable detail. The general conclusions have already been given in a preliminary bulletin (E. S. R., 7, p. 515), as were also the author's conclusions resulting from experiments with dendrolene and whale-oil soap, and from his study of the San José scale; but it may be noted in regard to the last insect that the author now finds it simpler to make a list of the plants that the insect does not attack rather than those

affected by it. A curious case of the persistence of the scale may be noted. One of the author's correspondents cut off his currant bushes early in the spring close to the surface of the ground, covering the stems with several inches of soil and allowing the young currant shoots to make their way through it. In most cases the scale made its way up through the soil and took possession of the shoots.

Concluding, the author thinks that every effort should be made to domesticate any known enemy of the scale, and that the introduction of *Sphaerostilbe* should be systematically carried on until the disease exists in all places where the scale is known to occur. But this is advised not with the hope of extermination so much as the lessening of the cost of control. The author also notes that it would be advisable to investigate the question as to whether Japan is really the home of the scale. He thinks it is not beyond the bounds of possibility that Nature will in time come to the aid of the farmer, and states that had the present season continued wet throughout the scale would have lost ground everywhere and gone into winter quarters in an enfeebled condition.

Report of the department of entomology, U. M. WEED (*New Hampshire Sta. Bul. 48, pp. 138-145, figs. 8*).—Observations on the tent caterpillar, its food plants, parasites, etc., are reported. The author says:

"The list of food plants of the American tent caterpillar is long and varied, and when compared with other caterpillars a peculiar fact is noticeable. In most cases where the food is varied the insects confine themselves to certain orders of plants, usually nearly related to each other, but the prime requisite with the present species seems to be that the plants shall be of a shrubby nature. The members of the rose family seem to be the natural food of the tent caterpillar, and very few, if any, of the shrubby and arboreal members of this family escaped."

Notes are given on the forest tent caterpillar, and the differences between it and the common tent caterpillar are pointed out. The cankerworm has done considerable damage in some localities, but in regions where it was destroyed by spraying in 1895-96 the outbreak appears to have been checked. Brief notes are given on the codling moth, oyster-shell bark louse, and scale bug.

Insects of the year, G. H. PERKINS (*Vermont Sta. Bul. 60, pp. 3-16, figs. 5*).—The bulletin gives notes on the insects which have been most common during the year and suggests treatment. The army worm and the chinch bug did not injure crops during the season. Currant and cabbage worms, horn flies, railroad worms, and aphids gave considerable trouble. The forest tent caterpillar was unusually abundant and destructive, especially to the apple and sugar-maple trees, often defoliating them. The oyster-shell scale of the apple was very injurious in some orchards. The San José scale has appeared in one place in the State. The round-headed apple-tree borer was very troublesome in several localities. The flat-headed borer also gave some trouble, but was less injurious than in the preceding year.

Four injurious insects, D. A. SAUNDERS (*South Dakota Sta. Bul.* 57, pp. 35-52, figs. 19).—The author considers the Rocky Mountain locust (*Melanoplus spretus*), grain aphid (*Siphonophora avenae*), spotted blister beetle (*Epicauta maculata*), and Uhler's green plant bug (*Lioderma uhleri*). The latter insect was first noticed in South Dakota in 1895. It has spread rapidly until it is now distributed over at least 10 counties. It is estimated that in 1897 3,500 acres of small grain and 800 acres of corn were totally destroyed by this insect. The young insect shows a special liking for turnips, radishes, potato blossoms, and young sweet corn. Cabbages, beets, and ruta-bagas were also attacked, but not well liked. Onions, parsnips, lettuce, tomatoes, carrots, and watermelons and cucumbers, were hardly touched.

"The insect inserts its bill beneath the epidermis of the soft, succulent part of the plant and draws so much nourishment therefrom that, especially where the bugs are abundant, the plant seldom recovers. Wheat is not disturbed until it is in the milk; the bugs then attack it in great numbers, 25 or more to a single head. A careful examination of many heads of wheat obtained from the infested regions fails to show any kernels that were missed by the bugs. The destroyed heads of wheat are as light as straw, there being nothing left in the chaff but the shrunken and shriveled hull of the grain. Sections made of such grains, the central part of which, in healthy grains, is densely packed with starch, is entirely empty and the gluten-containing cells contain but a few scattered grains.

The cornstalk is attacked early in the season; when it is a foot or two in length is when the greatest damage is done to it. In fact, if the bugs are numerous it is entirely destroyed. Later in the season they also attack the young ears, but at this time are not so destructive."

As to remedies, the author says: "Undoubtedly the best thing to do is to thoroughly and systematically burn every waste field, weed patch, and uncultivated ground." The burning should be delayed until all the bugs have come out of their winter quarters in the ground, unless the early ones begin to migrate. So far as known the bugs do not burrow in the native prairie.

The codling moth, M. V. SLINGERLAND (*New York Cornell Sta. Bul.* 112, pp. 69, figs. 21, pl. 1).—Some general historical notes on the codling moth are given. The author estimates that from one-fourth to one-half of the annual apple crop of the United States is destroyed by the codling moth—more than by all other insects combined. Among the food plants of the insect are noted apples, pears, wild haws, crab apples, and quinces, and the insect sometimes works on such stone fruits as plums, peaches, and cherries. The insect is described and figured in its various stages. Its life history is discussed at length, many quotations being made from old as well as recent literature. In regard to the place and time of laying the eggs the author says:

"During the past two years we have seen hundreds of the eggs on apples in New York orchards, and have never yet seen one on or down in between the calyx lobes on the so-called blossom end. We have seen eggs near the calyx, in old curculio scars, near the stem, and have found what appeared to be codling moth eggs even

on the leaves of the tree. Most of the eggs we found were glued to the skin, apparently without much choice as to location, on the smooth surface of the fruit. . . .

"From the only definite evidence we have, one can not escape the conclusion that, in the northern half of the United States at least, most of the eggs of the codling moth are not laid until a week or more after the petals of the blossoms have fallen from most varieties of apples; or usually during the latter part of May and the first half of June.

"The date of the falling of the blossoms varies considerably in different years, depending upon the weather conditions which may cause spring to open early or late. As these same conditions affect the date of the emergence of the moths, in general the above statement regarding the egg-laying of the insect will hold good."

The habits of the insect and its work in all stages are considered in detail, the views of various writers being given together with observations of the author. The following résumé is given:

"The codling moth appears in the spring about the time the blossoms are falling from apple trees and after a few days glues its tiny scale-like eggs onto the skin of the young fruit or even the adjacent leaves, where they hatch in about a week. The little apple worm usually finds its way into the blossom end where it takes its first meal and where it remains feeding for several days, finally eating its way to the core. In about three weeks it gets nearly full grown and makes an exit tunnel to the surface, closing the outside opening of the tunnel for a few days while it feeds inside. Emerging from the fruit, it usually makes its way to the trunk of the tree where it soon spins a cocoon under the loose bark. Usually the first worms to thus spin up in June or July soon transform to pupæ, from which the adult insect emerges in about two weeks, and eggs are soon laid from which a second brood of the worms hatch. In most of the more northern portions of the United States only a part of the worms of the first brood pupate or transform to moths the same season, but in the central, western, and southern portions there is a complete second brood, and in some portions even a third brood of the worms annually. In the fall all the worms spin cocoons wherever they may be, either in the orchard or in storerooms, and remain curled up in them as caterpillars until spring opens, when they transform, through the pupa, to the moth, thus completing their yearly life cycle."

Among the natural enemies of the codling moth the following are discussed: Bats, said to be the most efficient destroyer of the moths in California; a parasite of the codling-moth eggs (*Trichogramma pretiosa*); a parasite of the larvæ (*Macrocentrus delicatus*); an external parasite of the larvæ (*Goniozus* sp.); hair snakes, sometimes found in larvæ before leaving the fruit; the larva of the Pennsylvania soldier beetle (*Chauliognathus pennsylvanicus*), which devours the larvæ while they are getting ready to spin or before they leave the apples; the larva of the margined soldier beetle (*C. marginata*), which probably enters the fruit to feed on the codling worm; the larva of the two-lined soldier beetle (*Telephorus bilineatus*); the larva of the beetle (*Trogosita corticalis*) which feeds on larvæ and pupæ on the trunks of trees and is considered, with the exception of birds, the most efficient enemy of the codling moth in New York; the larva of a similar beetle (*T. laticollis*) the larva of a neuropterous insect occurring in the West; a tachinid fly (*Hypostena variabilis*); an ichneumon fly, the ring-legged pimpla (*Pimpla annulipes*), the grub of which lives in the body of the larvæ and pupæ of the codling moth; and the birds, considered the most

efficient aids in controlling the codling moth. Of the work of birds the author says:

"In our experience it was almost impossible to find anything but empty cocoons on any part of the tree in the spring except on the trunk at the surface of the ground and for a distance of from six inches to a foot above. One finds such an astonishingly large number of empty cocoons that it would seem as though the birds must get the larger percentage of the worms which go into hibernation in the fall. Among the birds which thus include the apple worm in their menu are the downy woodpecker, nuthatch, black-capped titmouse, bluebird, crow blackbird, kingbird, swallows, sparrows, wrens, chickadees, and jays. It is probable that most of the birds which winter in any locality include the apple worm in their dietary."

A recent suggestion to import a bird which in Germany is an enemy of the codling moth is discouraged, the results of the importation of the English sparrow being cited as a warning. The author expresses the opinion that the larval stage is the most vulnerable of all the stages of the insect's life. The pupa stage is very short. The moths can not be entrapped by lights, and it is doubtful if the egg can be destroyed by any means which can be ordinarily employed. As to the ways of combating the larvæ the author discusses jarring and picking infested fruit from the trees, the destruction of windfalls, trapping worms on tree trunks by banding, and spraying. Windfalls must be destroyed promptly since the larvæ have been shown to leave the fruit soon after it falls. Bands must be examined every 10 days from June until the latter part of August. After that it will not be necessary to disturb the bands again until late in the fall. The cost of this method of treatment during the season is considered to be about 4 cts. per tree. To show the reason for spraying soon after the blossoms fall, young apples and pears are figured. It is suggested that the greater success commonly observed in spraying apples than in spraying pears may be due to the fact that in the former the calyx lobes close up and hold any poison the calyx cup contains, while in the latter the lobes remain open and allow the poison to be washed away.

By way of summary the author says:

"Briefly stated, no panacea for the codling moth has yet been found, but by thorough work by a Paris-green spray, we can often save at least 75 per cent of the apples that would otherwise be ruined by the worms. Where more than 2 broods of the insect occur during the season, as in Kansas, Nebraska, Oregon, New Mexico, and neighboring localities in the West and in the South, the poison spray is not so effective, for although 75 per cent of the first brood of worms may be killed with the spray, the few worms left will form a sufficient nucleus for a large and very destructive second or third brood; in these localities the best that can be advised at present is to supplement the poison spray with the old banding system.

"To use the poison spray the most effectually, one must understand that it is necessary to fill the blossom end of each apple with poison within a week after the blossoms fall, for this is where the little apple worm gets its first few meals, and it is practically our only chance to kill it with a spray. Watch the developing fruit after the petals fall and be sure to apply the poison before the calyx lobes close, for while the falling of the blossoms is the signal to begin spraying, the closing of these calyx lobes a week or two later is the signal to stop spraying.

"While we thus have no new methods to offer and doubt if anything better than the poison spray will be found for combating this insect, we believe a better understanding of 'whys and wherefores' of the methods already in use will insure still greater success with them."

The bulletin contains a "bibliography of the most important contributions to the economic literature of the codling moth." The references, about 100, are arranged chronologically and date from 1635 to the present time.

Observations on the codling moth, F. W. CARD (*Nebraska Sta. Bul. 51, pp. 11-50, figs. 5*).—The bulletin gives original observations on the life history and habits of the codling moth, and the results of field and laboratory tests of remedies. The author points out the fact that in the West the remedies usually recommended for the moth have failed to give satisfactory results and that the habits and life history of the insect are not in accord with the statements made in the older literature of the subject, especially with regard to the eggs being deposited in the open calyx cup at the time of blossoming or soon after. Most varieties of apples in the station orchard in 1897 blossomed in the first of May and the calyx cups had practically all closed by the twentieth. The life history of the insect as given by the author is as follows:

"The first moths begin to emerge late in May. These deposit their eggs chiefly upon the upper sides of the leaves near by an apple. These eggs hatch in 8 or 10 days, more or less, according to the weather. The tiny larva, when it emerges, soon begins to seek for an apple in which to feed, though in some cases not until it has eaten out a small portion of the leaf near where it hatches. It seeks for a hiding place to protect it from its enemies, and the one most frequently available is that formed by the calyx lobes, which have closed, thus preparing a very safe and convenient dwelling until it can work its way into the fruit. These larvae begin appearing about June 1, varying somewhat with the season. They soon make their way to the center of the apple, eating out the portion about the core. When full-grown, which apparently occurs in from 10 to 14 days, they become pinkish in color, usually leave the fruit, and hunt for a convenient hiding place in which to spin their cocoons. Such a spot is commonly found beneath rough pieces of bark on the trunk of the tree. Apparently they leave the fallen apples and crawl up the trunk, or they may leave the apple when still upon the tree and crawl downward. The rough bark found at the forks between large branches is a favorite place, also injured portions where rotten wood or similar conditions occur. Sometimes they may change to pupæ within the apple, and Mr. Nutter expresses the opinion that the majority thus transform. This is common in confinement, but in our own observations we have never found pupæ in the apples about the orchard. The second generation of moths emerges about a month, or possibly a little more, after the eggs are laid. They are very irregular in time. Many moths are tardy in emerging from their winter quarters. These may pass through not more than two generations during the season, while those which emerge very early may pass through as many as four; consequently, to say that the codling moth is two-brooded, or three-brooded, or four-brooded is not to express the full truth, some being one, some another. Apparently the greater number pass through three generations. Few, if any, larvae transform to pupæ after September 1. From that time forward they weave themselves thicker cocoons than in summer, preparing to pass the winter within them. Those which are still in the apple may be harvested with the fruit and thus find

their place for transformation in crevices or among the refuse in the bins or barrels. The winter is passed in the larval stage, the change to pupæ being made in spring, and from thence the summer campaign as a moth is begun."

In discussing remedies the author notes the fact that the usual recommendation is to spray the trees with some arsenite as soon as the blossoms fall and repeat once or twice at intervals of ten days or two weeks, and shows that following this recommendation the first spraying would be made in Nebraska nearly a month before the larvæ appear. The only object of spraying early is to get a particle of poison into the calyx cup before the calyx closes. From observations extending over two seasons it was estimated that about 80 per cent of the wormy apples were entered by the calyx end. The author believes that the chances are against spraying affecting the 20 per cent of the larvæ which enter the apple outside of the calyx, and notes the fact that if this percentage of the first brood were to continue propagating itself throughout the season the crops of late apples might be nearly ruined. An attempt to trap the larvæ with sticky fly paper after they leave the apples to pupate resulted unsatisfactorily. The use of bands around the trees gave good results. Paper bands were applied in different ways, some being folded to allow the larvæ to enter between the folds. Out of 368 pupæ found on banded trees 322 were under the bands. In regard to this work the author says:

"It would seem from these results that the larvæ prefer the rough bark near the ground, and most of them get next to the bark, no matter how close the paper may be tacked to the tree, so that putting on the double fold with the hope of trapping them between the layers and thus quickly destroying them can not be depended upon."

Experiments at the station in spraying with Paris green were not entirely satisfactory on account of the unfavorable condition of the trees. From an examination made June 21 it was found that trees sprayed only on June 1 seemed to have been as well protected as those sprayed two or three times. The sprayed trees were, however, much freer from wormy fruit than unsprayed trees. Late spraying was tried on a very small scale in 1896. On July 10 a part of a tree was sprayed and on August 11 the apples were examined, with the result that 82 per cent of those taken from the unsprayed portion were wormy as against only 26 per cent of those taken from the sprayed portion. The spray used was very strong and injured the foliage so seriously that many of the leaves fell and the growth of the fruit was checked.

Various mixtures were tried in an attempt to find something that would adhere better than Paris green. The addition of sorghum to the spray gave no beneficial results. The addition of one tablespoonful of rye flour to a pailful of water added to the adhesiveness of the mixture. Lead arsenite adhered better than Paris green. Bordeaux mixture adhered well, and it is suggested that it may be mixed with arsenites to render them more adhesive.

From laboratory experiments with Paris green, Bordeaux mixture

and Paris green, and whale-oil soap, it was found that each of the substances has some value when used before the eggs hatch, but that neither of them destroy the eggs or are entirely effective in killing the larvæ. Apples sprayed with kerosene emulsion, one part standard mixture to 20 parts water, before the eggs hatched were entirely uninjured by larvæ, the eggs in some cases being apparently killed by the emulsion, and in all other cases the larvæ being killed before injuring the fruit. A single experiment in the field indicated that kerosene emulsion may be used to advantage against the codling moth.

Cooperative experiments were carried on at different places in the State. At Gibbon 1,700 trees were treated. Four sprayings were made with Paris green, 1 lb. to 200 gal. water. On harvesting the apples 80 per cent were found free from worms and in half of the other 20 per cent the damage was very slight. It is thought the percentage of wormy apples would have been greater had not many of the moths been killed in the storage rooms. The previous year, when the trees were unsprayed, not over 20 per cent of the apples were salable. At Arlington an orchard was divided into 6 sections, from 2 to 6 applications of Paris green being made at various dates in each of the sections. There was no marked difference in results in the different sections of the orchard, due, it is thought, to the fact that the moths go from one section to the other to deposit eggs for the late broods. There was considerable difference in the percentage of wormy apples of different varieties. For instance, 44 per cent of the Janet apples were wormy, as against only 20 per cent of the Ben Davis. At Geneva about 1,000 trees were sprayed twice with London purple at a total cost of only 2 cts. per tree. Another orchard was sprayed but once. The results were in favor of 2 sprayings.

The author gives the following suggestions for treatment:

"Spray with Paris green as generally recommended, about one week after the blossoms fall, or in time to get the calyx cups well filled with the poison so that they may close over and hold it there.

"Spray again with Paris green and Bordeaux mixture combined, or with kerosene emulsion, about June 1, or better still, observe carefully and apply this when the eggs are being laid in abundance on the leaves, which at Lincoln occurs about this date. Laboratory experiments indicate that kerosene emulsion will be more effective than Paris green at this time.

"Scrape the bark and place paper bands around the tree about the last of June, when the larvæ are beginning to leave the apple to pupate. Examine these two or three times, a week apart, and destroy the insects found beneath them.

"If these methods are not wholly effective, owing to the proximity of neglected orchards, or from an unusual abundance of moths, later spraying, with either Paris green and Bordeaux mixture, or kerosene emulsion, may do some good, but apparently can not be expected to be wholly effective. Late spraying with arsenites is much more likely to injure the foliage than earlier applications, and if the other methods are thoroughly followed, it will probably be unnecessary.

"If larvæ are still found in the apples in any considerable numbers toward the end of the season, place paper bands about the tree about September 1, or a little earlier. Leave them there until the fruit is gathered from the orchard, then remove, and destroy the larvæ hibernating beneath them.

"Screens placed over the windows and doors of the cellar or rooms where apples have been stored will prevent those larvæ which are taken in with the apples from escaping as moths in the spring."

The Orthoptera of Minnesota, O. LUGGER (*Minnesota Sta. Bul.* 55, pp. 91-386, figs. 188).—The bulletin gives the distribution, structure, and habits of the more destructive species of locusts, with methods of combating them; remedies for cockroaches and other orthopterous insects; an account of the parasites and other natural enemies of locusts; a description of the external anatomy of the two-striped locust (*Melanoplus bivitatus*); an account of the internal structure and metamorphosis of locusts; and a classification and technical description of the species of Orthoptera occurring in Minnesota.

In regard to remedies against locusts the author says:

"The true remedy consists in plowing, and wherever locusts are numerous this method has to be employed. Plow the soil containing the eggs during the autumn, if possible, as by doing so the surface of the plowed ground becomes thoroughly compact by wind, rain, and snow. Plowing in spring, if well done, and as early as possible, will also be successful, though in some cases, and especially in a dry season, a few locusts may succeed in reaching the surface."

To determine whether young locusts can reach the surface in plowed ground, eggs of *Melanoplus spretus* and *M. atlantis* were planted at different depths in flower pots containing soil similar to that from which the eggs had been removed. In one lot the soil was moistened occasionally and in the other kept dry. The results are shown in the following table:

Percentage of locusts reaching surface of soil with eggs placed at different depths.

Depths at which eggs were placed.	Soil kept dry.	Soil moistened.
	<i>Per cent.</i>	<i>Per cent.</i>
One inch.....	93	87
Two inches.....	86	43
Three inches.....	51	11
Four inches.....	13	1
Five inches.....	2	0
Six inches.....	0	0

Where locusts are not numerous enough to warrant plowing, burning the grass may be useful. Where eggs are deposited in large numbers in restricted areas, much good may be done by collecting and destroying them. To do this, especially where the soil is light, about an inch of the surface soil is removed and the eggs sifted out and buried. In case it is impracticable to plow, as in meadows and pastures, much good may be accomplished by poisoning the edges of adjoining grain fields. Locusts may also be poisoned in gardens by using poison bran mash as a bait. Hopperdozers are considered very useful in destroying locusts, but are "only a makeshift, to be employed when better remedies can no longer be used."

Cottonwood-leaf beetle; green arsenite, V. H. LOWE (*New York State Sta. Bul.* 113, pp. 23, pls. 6).—The results of a study of *Linna scripta* in its relation to the willow industry of the State during the last 2 years. During this time and the 2 years preceding the beetle in both adult and immature stages caused very serious injury to the willow industry by attacking the willow whips, causing them to branch and thus making them unfit for basket purposes. In experimental fields the willows were successfully protected by 3 applications of green arsenite in the proportion of 1 lb. to 100 gal. water. Other mixtures were also tried, among them green arsenite and whale-oil soap, 1 lb. of the latter being added to each 20 gal. of the mixture of the former.

Machines are figured and described which consist of a boat-like receptacle in which water is placed and covered with a film of kerosene; the beetles and larvæ are knocked into this receptacle as the machines are pushed or dragged between the rows of willows. The author recommends spraying the young trees until they are large enough for the machines, and using the machines after the trees are too high for thorough spraying by ordinary means. The importance of united efforts by willow growers is pointed out.

Green arsenite or Scheele's green, with which the experiments were made, is thought superior to Paris green; for in addition to its low cost it remains in suspension longer. When Paris green is mixed with water at the rate of 1 lb. to 150 gal. it sinks to the bottom within about 5 minutes, but green arsenite will remain in suspension for over 2 hours. The use of lime with the poison is recommended.

Plant lice—descriptions, enemies, and treatment, V. H. LOWE (*New York State Sta. Bul.* 139, pp. 646-664, pls. 4).—The bulletin discusses the classification and life history of plant lice, how they obtain their food, their natural enemies, remedies used in combating them, etc. The species of plant lice which were under observation are *Hyalopterus pruni* and *Myzus ribis*. The former are abundant on the plum and the latter on the currant. These are described, their distribution, life history, and food habits are noted, and partial bibliographies of each are given. Other species of plant lice attacking the plum and currant are noted.

Among the natural enemies of plant lice the author considers the following predaceous insects: *Anatis ocellata*, *Coccinella 9-notata*, *Adalia bipunctata*, *Megilla maculata*, an undetermined beetle, larvæ of the syrphus fly, and aphid lions, and the following parasitic insects: *Aphidius polygonaphia*, *Pachyneuron aphidivorus*, and *Isocratus vulgaris*.

Experiments were conducted in spraying with whale-oil soap, on which the following recommendations are based:

"Do not wait for the leaves to become curled, but spray thoroughly as soon as the first few lice are observed. Much depends upon the thoroughness of the first application. Direct the spray from below so as to drench the under surface of the leaves. Use a solution of good whale-oil soap, not weaker than 1 lb. to 7 gal. of water.

When the spraying has been neglected until the leaves have become badly curled, trim off the curled tips and spray at once with the whale-oil soap solution. This applies especially to fruit trees. In the case of currants and gooseberries, it will sometimes be found practical to pick off and destroy the leaves which are first infested in the spring."

Brief notes on the San José scale, H. P. GOULD (*New York Cornell Sta. Bul.* 111, pp. 587-592, fig. 1).—This consists of notes on the occurrence of the San José scale at Cornell University, methods of treatment, natural enemies, etc. The following summary is given:

"Whale-oil soap used at the rate of 2 lbs. to a gallon of water will kill the scale, but its use is more or less restricted on account of its consistency when cold and from the fact that it injures the foliage and buds if they are in other than a dormant condition. Kerosene applied at the rate of one part kerosene to four of water will destroy the scale. The results of spraying in the spring, compared with those obtained from late fall or early winter indicate that the scale is more susceptible to the action of insecticides in the spring than it is in the fall. Whale-oil soap in solution may be applied by means of a pump while it is hot, but after it becomes cold a brush or some similar implement is necessary to do thorough work. A spray pump with kerosene attachment is the most convenient apparatus for applying kerosene. There are several insects and fungus enemies of the scale, but it is yet doubtful if they are of much economic importance in the North. The San José scale does not seem to be very difficult to kill when insecticides are brought in contact with it. The difficulty arises chiefly from the fact that the scales are often more or less protected by the roughed bark, crevices, and other natural conditions of the host, and from the rapid increase of the pest. Great care and thoroughness are of paramount importance. When the work is thoroughly well done and frequently repeated, satisfactory results may be expected."

Inspection of nurseries and treatment of infested nursery stock, V. H. LOWE (*New York State Sta. Bul.* 136, pp. 573-602, pls. 5).—This bulletin gives an account of the inspection of nurseries in western New York and discusses the more important insects found. Experiments are reported in treating young stock infested with lice, in fumigating nursery stock, in spraying young grafts, etc. The following summary is given:

"Most of the nurseries inspected have been found practically free from insect pests of a serious nature. Ten important species have been found at different times, however, in sufficient numbers to do serious injury. In all cases efforts were at once made to clean out the stock thus infested. The most important insect which attacks nursery stock in this State is the San José scale. It is important to nurserymen not only because of the injury which it may do to the infested stock, but because it is greatly dreaded by both dealers and fruit growers alike. Hence stock from a nursery which is known to have been once infested does not find a ready sale.

"Experiments in dipping and spraying young nursery trees indicate that plant lice may be controlled in the nursery by dipping the curled tips of infested trees in a solution of whale-oil soap, 1 lb. to 7 gal. of water. The work should be done early in the season. Flea-beetles attacking young pear and apple trees may be held in check by spraying with green arsenite, 1 lb. to 100 gal. of water, and the canker-worm will succumb to the same treatment.

"The experiments in fumigating nursery stock with hydrocyanic-acid gas, when the stock is piled in the cellar for winter storage, indicate that this method may prove practical, thus avoiding the necessity of building special fumigating houses."

The peach-tree borer, C. F. BAKER (*Alabama Sta. Bul. 90*, pp. 27-32, *figs. 3*).—The characteristics and life history of the peach-tree borer are noted. The following remedies are suggested: Cutting out the larvæ and preventing the larvæ from entering the tree by tying tarred or building paper about the trunks or coating the trunks with a mixture to poison the larvæ or prevent their boring in. For the latter, whitewash with the addition of Paris green and soap or glue is recommended. White lead should be used with caution and only on old trees, as young ones may be injured by it. Painting tree trunks with the sediment of Bordeaux mixture resulted successfully. Dendrolene was applied to mature peach and plum trees, with the result that one-half of the trees were killed and the others seriously injured.

The fruit-bark beetle, C. F. BAKER (*Alabama College Sta. Bul. 90*, pp. 33-37, *figs. 5*).—The fruit-bark beetle is described and figured and its life history, distribution, and method of attack are noted. Burning badly infested trees, the application of whitewash to trunks and branches, and thorough culture are recommended as the best means of dealing with this insect.

The production of honey, W. S. PENDER (*Agr. Gaz. New South Wales, 9 (1898), No. 8*, pp. 897-907, *figs. 3*).—A paper presented before the Hunter River Agricultural and Horticultural Association, with a discussion.

Notes on the habits of some burrowing bees, J. B. SMITH (*Science, n. ser., 8 (1898), No. 195, p. 399*).—Notes are given on the burrows of *Colletes compacta*, *Andrena bicolor*, *A. ricina*, and *Angochlora humeralis*.

The periodical cicada in 1898, E. A. SCHWARZ (*U. S. Dept. Agr., Division of Entomology Circ. 30, 2. ser., pp. 3*).—It is noted that 2 broods of the cicada will make their simultaneous appearance this year, a 17-year brood at various places, from Wisconsin in the West to New York in the East, commencing to appear in the latter part of May; and a 13-year brood on both sides of the Mississippi River, from near the mouth of the Missouri southward to Louisiana, commencing toward the end of April. The list of localities where the insects will occur is given alphabetically.

Insects injurious to wild and cultivated roses in France, E. LUCET (*Les insectes nuisibles aux rosiers sauvages et cultivés en France. Paris: Paul Klincksieck, 1898, pp. 356, pl. 13, figs. 170; rev. in Ztschr. Pflanzenkrankh., 8 (1898), No. 3, pp. 188, 189*).—The work gives description and habits of these injurious insects, together with means for their destruction.

A review of the useful and injurious insects of Java, J. C. KONINGSBERGER (*Meded. S' Lands Plantentuin, 22 (1898), p. 53*).

The fruit-tree bark beetle, F. H. CHITTENDEN (*U. S. Dept. Agr., Division of Entomology Circ. 29, 2. ser., pp. 8, figs. 4*).—The circular considers briefly the general characteristics, methods of work, life history, and distribution of the fruit-tree bark beetle, its parasitic enemies, remedies, food, etc. Clean culture, burning badly infested trees, treatment of infested spots with kerosene emulsion, the use of detergent washes, such as whale-oil soap, soap and carbolic acid, soap and soda, and similar remedies are noted.

The fruit fly (*Producers' Gaz. and Settlers' Rec. [West. Australia], 5 (1898), No. 3, pp. 212, 213, figs. 2*).—A note is given, in which it is stated the recent investigations show that the fruit fly in Australia winters in two weeds (*Solanum sodomacum* and *S. nigrum*).

Tobacco-leaf miner, G. MCCARTHY (*Pennsylvania Dept. Agr. Rpt. 1897, pp. 721-726, fig. 1*).—A popular article dealing with the characteristics, habits, life history, and distribution of the tobacco-leaf miner, with notes on remedies.

A destructive beetle and a remedy, F. H. HALL and V. H. LOWE (*New York State Sta. Bul. 113, popular ed., pp. 8, pls. 2*).—This is a popular edition of Bulletin 113 of the station (see p. 467).

Three serious insect pests of eastern Australia, A. M. LEA (*Producers' Gaz. and Settlers' Rec. [West, Australia], 5 (1898), No. 3, pp. 171-174, fig. 1*).—The codling moth (*Carpocapsa pomonella*), Queensland fruit fly (*Tephritis tryoni*), and light-brown apple moth (*Cacacia responsana*) are briefly considered.

Bibliography of the more important contributions to American economic entomology, VI, N. BANKS (*U. S. Dept. Agr., Division of Entomology, pp. 273*).—This is part 6 of the bibliography begun by Mr. Henshaw and comprises the more important writings published between June 30, 1888, and December 30, 1896. Over 3,950 titles are listed.

Combating plant lice, F. H. HALL (*New York State Sta. Bul. 139, popular ed., pp. 5, pls. 4*).—This is a popular edition of Bulletin 139 of the station (see p. 467).

Killing aphid by vaporizing tobacco, J. N. MAY (*Amer. Florist, 13 (1898), No. 522, p. 1-118*).

The phylogeny of North American Eucleidæ, H. G. DYAR (*Science, n. ser., 8 (1898), No. 195, p. 400*).—This is a brief abstract of a paper read before Section F of the American Association for the Advancement of Science at its meeting in August, 1898.

Cyanid of potassium as an insecticide (*Gard. Chron., 3. ser., 24 (1898), No. 603, p. 50*).—Editorial notes are given on the use of this substance as an insecticide, and the author states the success which has attended its use in the United States warrants its trial in England.

Hydrocyanic acid as an insecticide, J. FISHER (*Amer. Gard., 19 (1898), No. 201, p. 741*).—The author describes his method of using hydrocyanic-acid gas to destroy insects in greenhouses.

Petroleum as an insecticide (*Bl. Zuckerrübenbau, (1898), No. 3, pp. 72-76*).

Arsenate of lead as an insecticide, K. SAMÓ (*Ztschr. Pflanzenkrank., 8 (1898), No. 3, pp. 173-175*).—Notes are given on the preparation, use, and efficiency of this insecticide.

Spraying calendar for 1898, L. R. TAFT (*Michigan Sta. Bul. 155, pp. 291-307*).—The bulletin gives a list of plants with directions for spraying each, a list of insect and fungus pests with directions for the treatment of each, and a list of fungicides and insecticides with directions for the preparation of each.

Legislation relating to insects and diseases of fruit trees, and preliminary report of the State inspector of nurseries and orchards, L. R. TAFT and D. W. TRINE (*Michigan Sta. Bul. 156, pp. 309-320*).—The bulletin gives the text of the San José and nursery inspection law of Michigan, a list of nurserymen and dealers who have taken out licenses according to the law, notes on other legislation relative to insects and diseases of fruit trees, etc.

FOODS—ANIMAL PRODUCTION.

A calorimeter for the human body, W. MARCET (*Proc. Roy. Soc. [London], 63 (1898), No. 396, pp. 232-242, figs 2*).—The author describes a calorimeter of suitable size for experiments with man. It consists of a wooden chamber lined with polished sheet copper. The capacity is 810.4 liters. The 2 walls are separated by a space of 45 cm. The outer wall is padded on the inside with cotton wadding and on the outside with several thicknesses of felt. There is a movable panel of the same construction as the walls which serves as a door. It is made to press tightly against a rubber cushion around the rim and is held in place with brass screws. This panel contains a window. Inside the chamber there is a chair in which the subject usually sits during the experiment.

The chamber is further provided with 2 fans which thoroughly mix the air and are so arranged that the current is not unpleasant to the person experimented upon. A vessel containing ice is suspended in the chamber and the water formed by the melting ice is collected in flasks suitably arranged. Comparatively little of the heat in the chamber is lost, since it is reflected from the walls. The heat generated causes the ice to melt and the amount of heat can be calculated from the amount and temperature of the water produced. In experiments due allowance is made for the heat generated by the revolution of the fans, and other necessary corrections are introduced.

Experiments to test the accuracy of the apparatus were made by introducing a jar of hot water into the chamber or by burning hydrogen gas. From these the author concludes that the calorimeter is very accurate. The calorimeter is so arranged that the respiratory products may be collected outside the chamber for analysis.

An experimental inquiry into the heat given out by the human body, W. MARCET and R. B. FLORIS (*Proc. Roy. Soc. [London]*, 63 (1898), No. 396, pp. 242-255).—Using the calorimeter described above, the authors made a number of experiments with men of various ages. In some of the experiments the authors themselves were the subjects. In several instances the respiratory products were collected for analysis. The air was inspired through the nose and expired through the mouth, a face piece with suitable tubes being worn. The usual plan was to collect the air expired for periods of twenty minutes to half an hour throughout the experiment. The author believes this gives a means of accurately determining the composition of the air expired while in the calorimeter, as the subject remains at rest. In one experiment the total respired air was collected and it was found that the volume expired in half an hour was proportional to the volume expired in one hour. The experiments were generally of an hour's duration and were made before and after eating and varied in other ways. The results are summarized as follows:

“(1) The amount of heat given out from the human body when tested on 2 successive half hours is found to be the same when the means of the calories are taken, although in each separate experiment the heat emitted may vary to some slight extent.

“(2) The heat emitted by the same person varies, and the extent of this variation is wider in some subjects than in others. Thus, in one case the calories emitted in one hour from 26 experiments varied from 122,121 to 80,639, or by 33.9 per cent of the larger figure. In 21 experiments with another subject they varied from 106,839 to 80,985, or by 24.2 per cent; and with a third subject in 11 experiments from 137,078 to 111,754, or by 18.5 per cent.

“(3) As a fact, irrespective of theory, the mean number of calories found from 3 different persons, under similar circumstances of food, etc., corresponding to 1 gm. of oxygen absorbed from the air, was the same, and can be stated in round numbers at 4,000. Had more experiments been done fasting, this figure would have shown a slight tendency to fall.

“(4) Although the mean calories per individual for 1 gm. oxygen absorbed under similar circumstances of food, etc., are the same, still, in the experiments taken singly, the number of calories corresponding to 1 gm. oxygen absorbed vary, and this

in a regular way. The greater the heat given out, the greater the calories produced for 1 gm. oxygen absorbed, and vice versa. Therefore, either a given amount of oxygen absorbed can produce different quantities of heat, or the oxygen found as absorbed does not represent that to which the heat is due. This second alternative appears the more probable.

“(5) The influence of a meal, as ascertained on 3 different persons, is well marked. Taking the midday meal, when mixed food is eaten, generally with a good appetite, the calories emitted about 2 hours after lunch show an increase over those given out about 3 or 4 hours after breakfast. The excess varies in different persons and according to the kind and amount of food taken.

“(6) The calories emitted per kilogram weight of the body are subject to marked variations in different persons.”

The feeding value of salt-marsh hay, J. B. LINDSEY and B. K. JONES (*Massachusetts Hatch Sta. Bul. 50, pp. 3-19, figs. 5*).—The composition and digestibility of 6 different varieties of salt-marsh hay are reported, together with illustrated descriptions of the salt grasses, remarks on the harvesting of salt hay, etc. It is stated that there are in Massachusetts about 23,000 acres of salt marsh, yielding some 21,000 tons annually, valued at \$193,000. “Large quantities of salt hay are used for litter, and for packing, while large amounts of the best grades are fed to horses and neat cattle.”

The hays included in this study were black grass (*Juncus gerardi*), fox grass (*Spartina patens*), branch grass (*Distichlis spicata*), redtop variety containing considerable sedge, cove mixture (a mixture of the redtop variety and black grass), salt-hay mixture (a mixture of branch grass, fix grass, and flat sage), and flat sage (*Spartina stricta maritima* var. ?).

The hay of black grass was rather damp and smelt moldy and was not relished by the animals, although they ate it. The branch-grass hay was in poor condition being very damp with a musty smell; it was not eaten readily by the animals.

The composition of the hay as compared with that of common hay was as follows:

Composition of hay of salt grasses.

	Water.	In dry matter.				Ash.
		Protein.	Fat.	Nitro- gen-free extract.	Fiber.	
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
English hay	13.00	7.55	2.48	48.49	36.68	4.89
Black grass	16.00	8.71	2.48	52.23	28.71	7.87
Fox grass	17.00	8.76	2.46	54.31	26.96	7.51
Branch grass	21.00	7.87	2.82	55.00	26.46	7.85
Redtop	13.00	7.80	1.82	51.54	32.32	6.46
Cove mixture	18.00	8.82	2.10	54.32	27.57	7.19
Salt-hay mixture	16.00	6.48	2.51	54.26	26.77	9.98
Flat sage	17.00	7.82	2.91	49.77	29.71	9.79

“In chemical composition they quite closely resemble an average quality of English hay. They contain about the same amount of protein, less fiber, and rather more extract or starchy matter, and ash. The excess of ash is due to the presence of salt. In fertilizing constituents, the same amount of nitrogen was found as in English hay and two-thirds as much phosphoric acid and potash.”

Digestion experiments on each kind of hay were made with sheep. Each sheep was fed 400 gm. of common hay and 500 gm. of salt hay daily, and from the results the digestibility of the salt hay was calculated. The results are summarized below:

Digestibility of salt-marsh hays.

	English hay for compari- son.	Black grass.	Fox grass.	Branch grass.	Redtop.	Cove mixture.	Salt-hay mixture.	Flat sage.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Protein.....	54	54	59	52	37	48	42	52
Fiber.....	58	57	57	25	56	60	58	60
Extract matter....	56	49	53	46	46	53	52	55
Fat.....	40	46	36	37	49	40	28	36

The results with branch grass are believed to be abnormal.

From the composition and the digestibility calculations are made of the amounts of digestible nutrients in 1 ton of the different hays as compared with common hay. The relative values of the salt-marsh hays containing 18 per cent of moisture as compared with English hay containing 14 per cent of moisture are given as follows: English hay 100, black-grass hay 90, fox-grass hay 85, branch-grass hay 84, redtop variety 84, cove mixture 88, salt mixture 82, and flat sage 88.

Formulas are given for grain mixtures to be fed with salt-marsh hay.

The digestibility of several sorts of distillery refuse, O. KELLNER, ET AL. (*Landw. Vers. Stat.*, 50 (1898), No. 3-1, pp. 297-316).—Experiments were made with 2 sheep on the digestibility of 5 sorts of distillery refuse. For purposes of comparison 3 tests were also made in which the only food consisted of meadow hay. As shown by microscopical analyses the different sorts of distillery refuse were made up as follows: (1) Maize and rye with some potato and barley; (2) largely oats and maize with a little barley; (3) maize, barley, and oats; (4) rye, maize, and oats with a little barley; (5) barley and maize with rye and potato. The composition of the different sorts of refuse is reported, as well as a number of tests on the best methods of determining dry matter and fat in distillery refuse and similar products. Two hundred grams of distillery refuse No. 1 was fed with 800 gm. of meadow hay, and in the other cases 300 gm. was fed with the same quantity of hay. The coefficient of digestibility of the refuse alone was calculated from the digestibility of the whole ration, using the value found for hay. The average coefficients of digestibility for the 2 sheep are shown in the table following.

Coefficients of digestibility of distillery refuse.

	Dry matter.	Organic matter.	Crude protein.	True albuminoids.	Fat.	Nitrogen-free extract.	Crude fiber.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Meadow hay	62.4	64.6	57.0	68.5	56.7	68.5	60.5
Distillery refuse I (maize, rye, some potato and barley).....	61.2	66.7	49.1	48.6	94.2	67.6	67.1
Distillery refuse II (largely oats and maize with a little barley).....	59.2	60.4	79.5	86.0	93.7	53.8	45.6
Distillery refuse III (maize, barley, and oats).....	78.5	81.1	68.6	73.8	94.3	82.9	91.8
Distillery refuse IV (rye, maize, oats with a little barley).....	74.2	76.1	63.8	63.8	91.9	82.1	69.1
Distillery refuse V (barley and maize with rye and potato).....	70.9	74.8	58.5	55.1	93.6	85.0	40.5

Concentrated feed stuffs, J. B. LINDSEY (*Massachusetts Hatch Sta. Bul. 53, pp. 24, figs. 3*).—In addition to definitions of terms used and a description of a number of feeds, the bulletin contains a report of the first official inspection of concentrated feeding stuffs in Massachusetts.

“ [Analyses are reported of] 4 different brands of gluten meal, 5 brands of gluten feeds, 10 different makes of wheat bran, 19 distinct brands of middlings, 22 different mixed feeds, besides a great variety of other feed stuffs, many without manufacturer's name or brand. The total number of analyses was 265.

“ The inspection shows the feed stuffs to be comparatively free from serious adulteration. Some show rather wide variations in composition, which it is hoped will be corrected in the future.

“ Many new materials, by-products from various industries, are constantly appearing, frequently without name, brand, or guaranty. This leads to much confusion as to feeding and actual commercial value on the part of the buyer. Materials of this character ought not to be purchased without a guaranty of quality. Guaranteed articles ought always to be given the preference.”

The author discusses the comparative commercial value of different feeding stuffs on the basis of nutrients contained in them, and suggests a number of grain mixtures to be fed with coarse fodders to dairy cows.

Fodders and feeds, E. B. VOORHEES and J. P. STREET (*New Jersey Stas. Rpt. 1897, pp. 76, 77*).—Analyses (food and fertilizing constituents) are reported of oats and peas, Japanese millet, cowpeas, soy-bean vines, barley and peas, green rowen, corn (stalks, kernel, cob, etc.), corn stover, corn fodder, corn silage, timothy and clover hays, shelled corn, corn sprouts, Atlas gluten meal, H. O. Feed, wheat bran, dried brewers' grains, and linseed meal. Japanese millet was shown to have the following percentage composition: Water 86.57, protein 1.49, albuminoids 1.02, fat 0.32, nitrogen-free extract 6.09, ash 1.78.

Breakfast foods, E. B. VOORHEES and J. P. STREET (*New Jersey Stas. Rpt. 1897, pp. 80-98*).—The authors studied a number of cereal foods generally classed as breakfast foods. These included 21 samples of prepared wheat flour, 12 of prepared buckwheat flour, 30 wheat foods, 17 oat foods, 7 maize foods, 3 rice products, and 3 sorts of zwieback. Four ordinary wheat flours and 3 buckwheat flours were also examined for purposes of comparison. The samples were purchased in open market.

The results of analyses of the different preparations, with the price per pound, are summarized in the following table:

Cost and composition of breakfast foods.

	Selling price per pound.	Water.	Protein.	Fat.	Nitrogen-free extract.	Fiber.	Ash.
Prepared wheat flour (average of 21 samples).....	5.6	10.70	10.47	1.21	72.32		5.32
Ordinary wheat flour (average of 3 samples).....	3.2	11.78	11.79	1.11	74.90		.42
Prepared buckwheat flour (average of 12 samples).....	5.1	11.45	8.61	1.26	73.07		5.67
Ordinary buckwheat flour (average of 3 samples).....	3.0	12.91	5.19	.90	80.19		.81
Wheat foods:							
Parched farinae (average of 2 samples).....	7.6	7.64	14.98	3.45	71.79	.77	1.37
Granose flakes (average of 3 samples).....	23.0	8.08	11.49	1.39	71.83	1.69	2.52
Jackson's granula.....	16.6	8.97	12.50	1.44	73.77	1.55	1.77
Wheat-germ meal.....	7.9	12.28	13.41	2.50	69.23	1.21	1.37
Wheatena (average of 3 samples).....	11.8	6.60	14.53	3.50	73.21	.87	1.29
Ralston's health wheat food.....	8.0	11.77	14.87	1.80	70.00	.48	1.08
Wheatlet (average of 3 samples).....	7.8	10.77	12.46	2.12	72.96	.81	.89
Cream of wheat (average of 2 samples).....	9.1	10.47	12.47	.91	75.77	.11	.29
Farina (average of 4 samples).....	10.3	12.71	11.07	.94	74.74	.17	.37
Shredded whole wheat (average of 3 samples).....	15.6	8.04	10.62	1.37	77.01	1.48	1.73
Leggett's cracked white wheat.....	7.5	10.04	12.84	1.78	72.52	1.23	1.59
Pettijohn's California breakfast food (average of 3 samples).....	6.3	9.87	9.97	2.12	75.31	1.72	1.46
Germea (average of 3 samples).....	8.2	9.71	9.13	1.75	77.79	.76	.87
Oat foods (average of 17 samples).....	6.4	7.94	16.72	7.65	65.38	.81	1.61
Maize foods:							
Cerealine flakes (average of 3 samples).....	11.8	10.33	9.75	1.11	78.56	.27	.28
Hominy (average of 4 samples).....	4.8	10.98	8.74	.76	79.01	.26	.26
Rice foods:							
Cook's flaked rice (average of 2 samples).....	13.4	9.50	7.90	.41	81.68	.17	.35
Rice in bulk (first quality).....	8.0	11.95	7.41	.33	79.96	.12	.23
Anger's zwieback (average of 2 samples).....	20.1	5.15	8.64	11.14	74.03	.17	.88
Sanitary zwieback.....	31.1	5.21	11.71	8.09	73.94	.10	.95

The prepared flours, commonly called pancake flours, and the oat preparations, though possessing different trade names, varied so little in composition that only the average results of each are quoted. The following oat foods, ranging in price per pound from 4 to 7.7 cts., are included in the average given in the table: Pin Head Oat Meal, Rolled Avena, Aunt Abbey's Rolled Cooked Oats, Cormack's Nudavene Flakes, Dundee Brand Oat Meal, Hecker's Oat Meal, Hornby's Oat Meal, Leggett's 15-Minute Oat Flakes, Martha Washington Rolled White, Oven-Baked Breakfast Rolled, and Quaker Rolled White Oats.

"All of the oat products, as well as a number of the wheat, contain considerable amounts of crude fiber—this constituent having been determined in nearly every case in order to show how fully the claims made in reference to the removal of the hull or covering, or woody matter, were verified. In one case it was claimed that the fiber had been entirely removed; this is not verified by the analysis. . . .

"[A study of similar products put on the market by different makers shows that] the variations in their composition are not marked, and that such as do occur are probably due to the variations in the composition of the original wheat. In the oat products the protein is the constituent that shows the widest variation, while in the corn and rice products the chief variable constituent is water. In the different samples of prepared flour wide variations occur in composition, doubtless due both to variations in the composition of the original flour and to the varying amounts and different character of the leavening materials added. In the wheat flours the widest range occurs in the content of protein. . . .

"In the case of the prepared flours, the chief object is to save the time of the housekeeper in their preparation for the table. The difference in composition between the plain flour and the prepared products is chiefly in the proportion of the constituents caused by the addition of leavening material. . . .

"Even assuming that the composition had not been altered in other respects, i. e., the food value has not been reduced, the addition of 5 per cent of mineral matter has caused an increase of 75 per cent in the cost per pound of the product."

In all the different classes the price for practically the same kind of preparation was found to vary within wide limits. In some cases the high price was perhaps due to some special method of preparation. The claims made for many of these foods were not found to be justified by their composition. "These claims, extravagant in some instances, should have but little weight with consumers, as the actual amount of nutriment furnished [by similar products] does not greatly differ."

A further study of the changes that occur in the process of baking bread, L. A. VOORHEES (*New Jersey Stas. Rpt. 1897, pp. 98-103*).—In continuation of previous work (E. S. R., 9, p. 79) a study was made of the changes which the nutrients undergo in baking bread. A number of experiments are reported in which the bread and the ingredients from which it was made were analyzed. Baking powder was used for leavening and milk was added as a source of fat. In several instances a flour was used which had been previously extracted with ether.

The dry matter was almost entirely recovered in the bread but this was not the case with the fat. The fuel value of the bread was about the same as that of the ingredients from which it was made. A loss of fat was also observed when the flour was made into dough and carefully dried without baking.

In the author's opinion the loss of fat is accounted for by the fact that the gluten hinders the solvent action of the ether. The work is not regarded as final.

Digestion and feeding experiments, W. H. JORDAN and C. G. JENTER (*New York State Sta. Bul. 141, pp. 691-720*).—Experiments are reported on the digestibility of a material prepared like the so-called "new corn product," on the agreement between the calculated value of a ration and its value as shown by actual experiment, and the relative nutritive effect of rations from unlike sources.

The new corn product (pp. 693-701).—This material, also known as Marsden's Stock Food, is a by-product obtained in the manufacture of cellulose from the pith of cornstalks for packing the hulls of ships (E. S. R., 9, p. 76). For the experiments about 200 lbs. of well-cured corn stover was divided into bundles, the leaves and husks stripped from one-half of each bundle, and the pith removed from the stalks. The leaves and husks formed 65.2 per cent of the total weight, the stalks minus the pith 24.5 per cent, and the pith 10.3 per cent. The stalks without the pith were ground to a coarse meal, which was said to be not quite as fine as the "new corn product." The composition of the different parts was found to be as follows:

Composition of corn stover and pith.

	Water.	Protein.	Fat.	Nitrogen-free extract.	Fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Whole stover.....	19.81	5.22	3.19	53.46	32.45	5.68
Stover without pith.....	12.21	5.24	3.09	53.93	32.52	5.22
Pith.....	13.27	3.48	5.62	52.77	33.61	4.52

"The pith, instead of being nearly pure cellulose, is at least two-thirds something else, and there is no reason for supposing that the pith of other lots of maize would be essentially unlike this sample."

A somewhat detailed study was made of the ether extract of the different materials. It was found that corn stover contained 0.82 per cent of carbohydrates soluble in water and 0.21 per cent soluble in malt extract, while the stover without the pith contained 0.61 and 0.29 per cent, and the pith 1.37 and 0.11 per cent, respectively. That is, the proportion of sucrose, starches, and other carbohydrates does not vary greatly in the 3 materials.

Digestion experiments of 8 days' duration (the first 3 days being preliminary) were made with 4 wethers. In one period the 4 sheep were each fed the same amount of corn stover per day, and in another period 3 of the sheep were fed the same amount of corn stover without the pith. The experiments were made by the usual methods. The results are shown in the following table:

Coefficients of digestibility of corn stover with and without the pith.

	Dry matter.	Organic substance.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Whole stover:							
Sheep 1.....	53.9	56.7	10.7	69.0	56.5	63.2	7.7
Sheep 2.....	54.6	58.1	17.1	77.4	57.6	63.5
Sheep 3.....	52.7	56.3	16.7	74.2	54.5	63.8
Sheep 4.....	52.9	55.8	22.0	76.3	58.8	66.9	5.1
Average of 4 sheep.....	53.5	56.7	16.6	76.2	56.8	64.3
Stover without pith:							
Sheep 1.....	53.6	55.3	16.5	69.8	55.7	59.6	21.8
Sheep 3.....	55.1	57.2	28.1	75.3	55.5	63.1	15.6
Sheep 4.....	56.7	59.0	16.9	70.9	58.5	65.5	14.7
Average of 3 sheep.....	55.1	57.2	20.5	72.0	56.6	62.7

"We do not have here any evidence that the removal of the pith of the maize plant materially increases the food value of the remaining portion. One sheep digested more from the stover containing the pith and 2 digested less, the average being not greatly different in the 2 cases.

"The real test of the digestibility of a feeding stuff is the digestibility of the organic matter, because in the case of such materials as corn stover the accidental mineral matter is a modifying factor. One-half of 1 per cent more of organic matter was digested from the stover without pith than from that with pith, a difference so small as to be well within the limits of error of such work."

The results are compared with those obtained at the Maryland Station (*E. S. R.*, 9, p. 76; 10, p. 75).

Calculation of the value of rations (pp. 701-712).—Experiments were made with 4 sheep to compare the digestibility of mixtures of unlike materials furnishing practically like amounts of nutrients, and to compare the digestibility of the same rations when fed in large and small amounts. There were 2 periods of 5 days each. The rations were as follows:

Constituents and amounts of rations.

	Period 1.		Period 2.	
	Full ration No. 1. Sheep 1 and 2.	Half ration No. 2. Sheep 3 and 4.	Full ration No. 2. Sheep 1 and 2.	Half ration No. 1. Sheep 3 and 4.
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
Timothy hay	100	150	300	50
Corn silage	800	250	500	400
Oats, ground	100	50
Peas, ground	120	60
Malt sprouts	20	40
Brewers' grains	30	60
Buffalo gluten feed	30	60

The coefficients of digestibility are given in the following table:

Coefficients of digestibility of mixed rations by sheep.

Period.		Dry matter.	Organic sub- stance.	Protein.	Fat.	Nitrogen- free ex- tract.	Crude fiber.	Ash.
1	Full ration No. 1:	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
	Sheep 1	69.5	71.8	70.7	79.3	75.7	59.0	13.1
	Sheep 2	69.3	71.7	71.0	81.8	75.2	58.9	13.8
	Average	69.4	71.7	70.8	80.5	75.4	59.0	13.4
	Half ration No. 2:							
2	Sheep 3	66.9	68.7	69.8	76.5	69.5	64.8	27.6
	Sheep 4	65.1	67.4	71.7	75.7	69.0	59.9	15.5
	Average	66.0	68.0	70.7	76.1	69.2	62.3	21.5
	Full ration No. 2:							
	Sheep 1	62.2	64.7	69.7	73.9	65.2	59.0	9.7
2	Sheep 2	61.1	63.8	60.9	73.8	64.9	61.1	4.1
	Average	61.6	64.2	65.3	73.8	65.0	60.0	7.9
	Half ration No. 1:							
	Sheep 3	75.7	77.2	76.0	82.1	79.4	70.3	40.6
	Sheep 4	73.1	75.4	75.2	82.2	78.6	64.2	20.8
Average	74.4	76.4	75.6	82.1	79.0	67.2	30.7	

Since the results show that the half rations had higher coefficients of digestibility than the whole rations, the conclusion is drawn that when consumed in small amounts feeding stuffs are more digestible than when consumed in large amounts.

Using the coefficients of digestibility obtained above, the authors calculated the amounts of digestible nutrients in 2 mixed rations like those fed, except larger, and compared the results with those calculated from average tables of composition and digestibility, as follows:

Digestible nutrients in the two rations as calculated and as actually determined.

	Calculated from averages.				Determined.			
	Organic matter.	Protein.	Carbohy- drates.	Fat.	Organic matter.	Protein.	Carbohy- drates.	Fat.
	Lbs.	Lbs.	Lbs.	Lb.	Lbs.	Lbs.	Lbs.	Lbs.
Ration 1: Timothy hay 5 lbs., corn silage 40 lbs., ground oats 5 lbs., ground peas 6 lbs.	16.1	2.21	13.31	0.57	16.0	2.14	12.89	0.99
Ration 2: Timothy hay 15 lbs., corn silage 25 lbs., malt sprouts 2 lbs., brewers' grains 3 lbs., Buffalo gluten feed 3 lbs.	16.2	2.24	13.1	.83	16.22	2.25	12.96	1.01

Since the results agree so nearly, the conclusion is drawn that when the value of rations is calculated by the ordinary tables of composition and digestibility the actual value of the rations is shown.

The relative nutritive effect of rations from unlike sources (pp. 712-720).—In the rations mentioned above the total amounts of nutrients as expressed in terms of protein, fat, and carbohydrates are about the same, yet it does not follow that the rations have the same actual feeding value, since the nutrients in different feeding stuffs are present in different forms. The authors determined the relative amounts of the different carbohydrates in the nitrogen free extract of the various feeding stuffs used, assuming all the carbohydrates soluble in malt extract to be starch and sugar. The results follow:

Composition of carbohydrates in feeding stuffs.

	In water-free materials.			Proportion of nitrogen-free extract not starch and sugar.
	Total nitrogen-free extract.	Nitrogen-free extract soluble in malt extract.	Nitrogen-free extract insoluble in malt extract.	
	Per cent.	Per cent.	Per cent.	Per cent.
Timothy hay	51.9	15.7	36.2	70.0
Corn silage	55.3	26.4	28.9	52.3
Oats	65.3	50.3	15.	23.0
Peas	63.5	53.9	9.6	15.1
Malt sprouts	49.2	22.9	26.3	55.5
Brewers' grains	43.8	12.9	30.9	70.5
Buffalo gluten feed	59.0	37.1	21.9	37.1

Using the above values, it is calculated that ration 1 furnished 8.21 lbs. of starch and sugar, 5.33 lbs. of other nitrogen-free extract, and 4.52 lbs. of fiber; and ration 2 furnished 5.43 lbs. of starch and sugar, 8.48 lbs. of other nitrogen-free extract, and 6.53 lbs. of fiber. Assuming that all the sugar and starch in both rations was digestible, it is calculated that ration 1 contained 1.99 lbs. of digestible nitrogen-free extract other than starch and sugar, and 2.67 lbs. of digestible fiber, and ration 2, 3.61 lbs. and 3.92 lbs., respectively.

"From a theoretical point of view, when we consider that the pentose sugars formed may be less assimilable than the hexose, and that cellulose digestion may in part be due to destructive fermentations, it is reasonable to admit the possibility of unlike nutritive values for a unit of digestible material from these two sources; but the demonstration of this fact, if it be a fact, is a difficult matter. A large difference in the value of two rations may be shown, perhaps by ordinary feeding trials, but small differences may be obscured by the errors to which such experiments are subjected."

An experiment was conducted with 2 lots of 5 milch cows to learn "whether the milk-producing capacity of a ration is modified by the sources of the digestible compounds, other conditions being uniform."

Some of the animals were in the early stages of lactation, but "none were so far advanced as to endanger the reliability of the data." After a preliminary experiment of 5 days the test, which covered 2 periods of 30 and 33 days, respectively, was begun March 2. During the first period lot 1 was fed ration 1 mentioned above, and lot 2 was fed ration 2. In the second period the rations were reversed.

The amounts of food eaten and the yield of milk and milk solids for each cow during each period are recorded. On ration 1 the cows consumed on an average per day 15.26 lbs. of digestible matter and produced 2.74 lbs. of milk solids, and on ration 2, they consumed 14.8 lbs. of digestible matter and produced 2.73 lbs. of milk solids.

"The results furnish no testimony in favor of the superior quality of ration No. 1, i. e.—in favor of the ration containing the larger proportion of easily digestible carbohydrates that belong to the hexose group. . . ."

"If a certain class of carbohydrate compounds possesses a superior nutritive value, the fact must be brought to light through some method of investigation more searching than feeding experiments of this character.

"It is certainly shown that in one case at least the commercial feeding stuffs of the by-product class were successfully substituted for such grains of high quality as oats and peas.

"Moreover, a much larger percentage of the digestible dry matter of the ration was supplied in timothy hay and silage in the first ration than in the second ration, the proportion being about 70 : 55 in the 2 cases, but as has been stated no evidence appeared that the second ration was inferior to the other. Such an outcome is encouraging to those farmers who wish to avoid the purchase of cattle foods by feeding largely home-grown fodders and purchasing sparingly such grains as are best calculated to supplement hay and silage."

Agricultural feeding stuffs, their feeding value and use, together with directions for preparing rations for farm animals, E. HASELHOFF (*Die landwirtschaftlichen Futtermittel, ihr Futterwert und ihre Verwendung, nebst Anleitung zur Aufstellung von Futterrationen für die landwirtschaftlichen Nutztiere. Neudamm: J. Neumann, 1898, pp. 173*).—Preface by O. König.

Market prices of commercial feeds, E. B. VOORHEES and J. P. STREET (*New Jersey Stas. Rpt. 1897, pp. 78, 79*).—The market prices during the past few years of a number of commercial feeding stuffs are reported.

The amount of nonprotein nitrogen in straw and chaff of various sorts, P. HOLDEFLEISS (*Ueber den Gehalt der reifen Stroh- und Spreuarten an nichtweissartigen stickstoffhaltigen Stoffen. Inaug. Address. Halle: C. A. Kämmerer & Co., 1897; abs. in Centbl. Agr. Chem., 27 (1898), No. 8, pp. 532-534*).—The author reports the determination of the total protein (by the Kjeldahl method) and the albuminoid nitrogen (by the Stutzer method) in a large number of varieties of straw, hulls, etc. The results are arranged in tabular form.

Problems in feeding. T. L. HAECKER (*Indiana State Dairy Assoc. Rpt. 1897*, pp. 137-143).—General remarks on the relative value of different feeding stuffs.

Some results in stock feeding. F. H. HALL (*New York State Sta. Bul. 141, popular ed.*, pp. 6).—This is a popular edition of Bulletin 141 of the station (see p. 471).

Summary of the investigations on the nutrition of man and animals carried on in the United States during the last two years. E. GAIN (*Assoc. Française Advancement Sci., Congrès Saint-Étienne, 1897*, pp. 820-833).—The author notes, in many cases with some detail, the principal recent publications on the food of man and animals issued in the United States. In most cases the articles cited were publications of the United States Department of Agriculture or of the Agricultural Colleges and Experiment Stations.

Bread (*Diet. and Hyg. Gaz.*, 14 (1898), No. 9, p. 580).—A brief note calling attention to the fact that the handling of bread by bakers and their assistants is a menace to health. In Berlin agitation on this subject has resulted in placing the loaves as taken from the oven in paper bags, the ends of which are twisted.

Wheaten bread. TISON (*Le pain de froment. Paris: A. Maloine, 1898; rev. in British Med. Jour.*, 1898, No. 1973, p. 1262).—The author believes that the bran should be rejected in grinding wheat, but that improvements in grinding should be sought, as the present method rejects too much. Steel grinders are recommended. The tegument and pericarp are not regarded as digestible by man and whole-wheat bread is condemned on the basis of hygiene and economy.

The medicinal value of fruit as food. C. T. SAUER (*Amer. Gard.*, 19 (1898), No. 189, pp. 558, 559).—The composition and properties of a number of fruits are discussed. The author is of the opinion that fruits do not possess any great medicinal value, but are to be regarded as food adjuncts, their chief virtue as medicines consisting in furnishing the blood with potash salts.

Potato flour in Austria. F. W. MAHAN (*U. S. Consular Rpts. 1898, No. 216, pp. 68, 69*).—Potato flour, also known as potato starch, which is used to a considerable extent by bakers and confectioners, is described and an analysis quoted.

Nutritive value of mushrooms (*Diet. and Hyg. Gaz.*, 14 (1898), No. 8, pp. 487, 488).—Attention is called to the small amount of actual nutrients in mushrooms, and extracts from early works are quoted which show that this fact has been long recognized.

The need of meat inspection (*Diet. and Hyg. Gaz.*, 14 (1898), No. 8, pp. 497-499).—The article quoted from L. Pierson in *Public Health* describes the conditions under which animals are slaughtered in Philadelphia and insists upon the need of some more adequate system of meat inspection, the municipal abattoir being recommended.

Composition of meat peptones. A. DENAEYER (*Jour. Pharm. et Chim.*, 6. ser., 6 (1897), p. 357; *abs. in Vrtljschr. Chem. Nahr. u. Genussmth.*, 12 (1897), No. 4, p. 491).

The composition of fish, crustaceans, and mollusks. BALLAND (*Compt. Rend. Acad. Sci. Paris*, 126 (1898), No. 24, pp. 1728-1731).—The composition of a considerable number of fish, crustaceans, and mollusks sold in Paris is reported.

On the formation of products of proteid digestion in the body, their identification, and fate. A. MEYER (*Ueber den Nachweis und die Entstehung der Produkte der Eiveissverdauung sowie über ihr Schicksal im Organismus. Inaug. Diss., Heidelberg, 1898, pp. 41; abs. in Hyg. Rundschau* 8 (1898), No. 8, p. 392).

The influence of consuming different quantities of water on the excretion of water vapor and carbon dioxid by man. P. LASCHTSCHENKO (*Arch. Hyg.*, 33 (1898), No. 1-2, pp. 145-150).—In experiments with man the amount of carbon dioxid and water vapor excreted through the lungs was not materially affected by the amount of water consumed.

Note on the excretion of water vapor through the lungs. M. RUBNER (*Arch. Hyg.*, 33 (1898), No. 1-2, pp. 151-154).—The author found in experiments with man that less water vapor was excreted through the lungs when reading aloud than when singing; still less was excreted when deep breathing was practiced, and least of all when the subject remained perfectly quiet.

Feeding of calves with potato flour and skimmed milk, J. SCHULTZ (*Landmansblad*, 31 (1898), No. 22, pp. 302, 303).

Feeding experiments with swine, P. HANSSON (*Meddel. K. Landtbr. Styr.*, 7 (1897), No. 42, pp. 155, 156).—A comparison of rice meal, molasses feed, and ground grain for swine.

The native breed of cattle in Gotland, G. AF WETTERSTEDT (*Landtmannen*, 9 (1898), No. 25, pp. 395-397, pls. 2).

The marketing of poultry, E. BROWN (*Jour. Roy. Agr. Soc. England*, 3, ser., 9 (1898), Pt. II, pp. 276-286).—Marketing poultry in England and some other countries is discussed, and suggestions made for improving this industry in England.

Drawn vs. undrawn poultry (*Dict. and Hyg. Gaz.*, 14 (1898), No. 8, p. 487).—From experiments, which are briefly reported, the conclusion is reached that under "precisely the same conditions of temperature and humidity drawn fowls will keep from 20 to 30 days longer than those not drawn. The presence of undigested food and of the excrementitious substances in animals which have been killed most certainly favors tainting of the flesh and general decomposition. The viscera are the first parts to show putrescence, and allowing these to remain within the body can not do otherwise than favor infection of the flesh with bacteria and ptomaines, even if osmosis does not actually carry putrid juices to contiguous tissues. Hunters know the value of drawing birds as soon as possible after they have been shot, in order to keep them sweet and fresh and to prevent their having a strong intestinal flavor.

"That the opening of the body of an animal and exposing the internal surfaces to the air may have some influence of itself in hastening putrefaction is admitted; but when the process of 'drawing' is properly conducted this secondary objection to its immediate performance may be entirely set aside. Absolute cleanliness should be maintained throughout the operation, and if the entrails are torn and their contents allowed to come in contact with the flesh of the animal its interior should be at once washed out with clean cold water and afterwards with a solution of common salt and the carcass hung up until thoroughly dry."

DAIRY FARMING—DAIRYING.

Dairy husbandry, C. B. LANE (*New Jersey Stas. Rpt.* 1897, pp. 163-192, pls. 2, *dgms.* 1).—This includes an abstract of Bulletin 122 of the station (E. S. R., 9, p. 790) and an account of the dairy work during two seasons. The growing of various soiling crops and other forage crops on the farm is described, with the order in which the soiling crops were planted and harvested, the amount of food nutrients which they furnished, and the cost of production.

The production of food materials during a 4-year rotation which had been carried on at the farm is shown in the following table:

Food materials produced and fertilizing materials removed in a rotation.

	Food constituents.				Fertilizing constituents.			
	Protein.	Crude fat.	Nitrogen-free extract.	Fiber.	Ash.	Nitrogen.	Phosphoric acid.	Potash
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Field corn, 1893	341.9	100.7	2,127.7	638.5	174.8	54.5	26.4	32.2
Crimson clover and fodder corn, 1894	909.3	237.6	4,962.4	108.1	439.0	145.8	44.6	87.3
Fodder, rye, and oats, and peas, 1895	569.6	170.2	2,693.6	446.1	355.1	91.1	47.1	97.4
Mixed hay and forage, 1896	300.4	74.5	1,422.9	900.8	161.8	48.2	15.6	53.1
Total	2,121.2	583.0	11,206.6	2,093.5	1,130.7	339.6	133.7	270.0
Average per year	525.0	145.0	2,801.0	523.0	282.7			

The arrangement of soiling crops in 1896 and 1897 is described and the yields in each case are given. In 1896 they furnished "a continuous supply of food from May 1 to November 1, and the produce from 7 acres will supply sufficient roughage for 25 cows for the entire period." In 1897, "with the exception of a week in June, when silage was used, the dairy herd was fed entirely upon soiling crops from May 1 to October 20." The soiling crops in both years consisted largely of leguminous crops grown alone or with oats or barley.

Notes are given on the growing of the different soiling crops and a test is reported on the comparative earliness, manner of growth, and yield of 8 standard varieties of Canada field peas. "All varieties stood up well. The crop was cut with a mowing machine while most of the peas were in bloom. The Prussian Blue proved to be the best yielder, while the Mummy, Green Field, and Green Scotch all made a vigorous growth."

The yields of milk upon the different soiling crops are tabulated. The aim was to furnish an equivalent amount of dry matter from each crop.

"The feeding of the crimson clover resulted in a gain in milk flow on the part of all the animals, the gain per day ranging from 3 to 3.5 lbs., an average per cow for the whole of 1.8 lbs., or 8 per cent. In the comparison of the crimson clover and mixed grasses there are 12 cases ranging from 0.7 to 2.2 lbs., with an average of 1.3 lbs., or over 6 per cent. The mixed grasses consisted chiefly of red and white clover and redtop. In the case of silage and mixed grasses, the silage being introduced for comparison with green forage, there was a loss [on silage] in every case varying from 0.1 to 2.8 lbs., with an average loss of 1.9, or over 7 per cent.

"In the case of silage *vs.* oats and peas, and oats and peas *vs.* peas, but little difference in the average yield per cow is noticed, though individual differences are quite marked. In the case of oats and peas *vs.* oats, and oats and peas *vs.* corn fodder, and in corn fodder *vs.* millet, there are decided losses [on silage], ranging from 3 per cent to over 7 per cent."

The cost of milk production for one year, ending April 1, 1897, is given. The herd averaged 23 cows for the year.

"The average cost of the daily ration is 11.6 cts., and of this 4.99 is due to purchased feeds and 6.61 to the cost of farm foods, so that the farm furnished 57 per cent of the total food. This is not so large a proportion as is desirable, and is due in part to the fact that there was but little roughage on hand when the station took charge of the farm, on April 1, 1896; besides, no provision had been made for early forage crops, as rye and clover, consequently a larger proportion of feeds was used during the first 3 months of the year. The cost of food per quart of milk was 1.5 cts., of which 0.616 is due to purchased feeds and 0.854 to farm crops.

"[Taking into account the cost of labor and the interest on and the decrease in the value of the herd] the cost per hundred was \$1.14. At \$1 per hundred, the price received in rural districts, cash profits from the business are not apparent. The profits, if any, must be found in the manure heap. In the calculation of the cost of farm foods the manure was charged at the rate of \$1.50 per ton. Careful weighing of the manure deposited in the stable shows that the amount produced averaged 60 lbs. per day per cow, or a total for the herd of 252 tons per year.

"In selling for \$1 per hundred, the receipts are \$203.95 less than the expenses, this difference representing the cost of the manure, which would be 81 cts. per ton. The

difference between this cost (81 cts.) and the actual charges made for it in the growing of the crops, \$1.50 per ton, viz, 69 cts. per ton, would amount to \$173.88 on the total amount produced—a gain too small to make the business pay. . . .

“At 3 cts. per quart the farm would sell its home-grown produce to the dairy at profitable prices, viz, \$2.78 for soiling crops, \$5.56 for silage, and \$8.31 per ton for dried corn fodder, a gain on the crops over cost of production of \$1.38 per ton for soiling crops, \$2.79 for silage, and \$3.31 for dried corn fodder, besides an additional gain represented by the 252 tons of manure.”

Dairying in relation to soil exhaustion is considered, and a table is given showing the amounts of fertilizing materials contained in the feeding stuffs purchased and in the milk produced by the herd of 23 cows. According to this the feeding stuffs purchased contained 851 lbs. more nitrogen, 640 lbs. more phosphoric acid, and 214 lbs. more potash than in the milk sold from the farm. A record of the herd is given for one year, ending April 1, 1897, and the record of individuals is considered. The record of the best and poorest cows from the standpoint of milk and butter production and the averages for the herd are summarized in the following table:

Records of best and poorest cows for milk and butter production.

	Animal yield.	Value of product.			Cost of feed.	Gain over cost of feed with—		
		Milk at 1 ct. per lb.	Milk at 3 cts. per quart.	Butter at 20 cts. per lb.		Milk at 1 ct. per lb.	Milk at 3 cts. per quart.	Butter at 20 cts. per lb.
Milk production:	<i>Pounds.</i>							
Best cow	8,303	\$83.03	\$114.26	\$42.34	\$40.69	\$71.92
Poorest cow	4,413	44.13	60.74	42.34	1.79	18.40
Average cow	6,314	63.14	86.89	42.34	20.80	44.55
Butter production: <i>a</i>								
Best cow	405	\$81.08	42.34	\$38.74
Poorest cow	202	40.43	42.34	— 1.91
Average cow	313	62.70	42.34	20.36

a Calculated.

“The range in percentage of butter fat was from 2.8 per cent to 6.4 per cent, with an average of nearly 4.3 per cent.

“The best milk cow was the second butter cow; the best butter cow was the fifth in order in largest milk yield.”

The claim that for profitable milk production a cow should produce at least 5,000 lbs. of milk per year, and for profitable butter production at least 200 lbs. of butter, appears to be supported by the year's record.

The milk of the herd is sold on the milk route. The method used in handling the milk, care of utensils, and waste in handling and delivering are discussed, and a brief description is given of the new dairy house.

An article on seeding grass and crimson clover is noted elsewhere (p. 431).

Milk production with salt-marsh hays, J. B. LINDSEY and B. K. JONES (*Massachusetts Hatch Sta. Bul. 50, pp. 19-48*).—Experiments are reported with 2 lots of 6 cows each in which 6 different salt-marsh hays

(see p. 472) were compared with common hay ("English hay"). A constant basal ration of wheat bran, Chicago gluten meal, and corn silage was fed, and in addition to this 10 to 12 lbs. of salt or English hay was fed. About 1 lb. more of salt hay was fed than of common hay, as the former contained from 6 to 8 per cent more water. The periods lasted from 14 to 17 days, with preliminary periods of 5 or 7 days intervening. The results are tabulated in detail, and analyses are given of the feeding stuffs used and of the milk of individual cows.

A summary of the results, with the averages for the salt hays and for English hay, is shown in the following table:

Summary of results of feeding salt-marsh hays to cows.

Periods.	Basal ration and—	Average amount	Dry	Diges-	Average yield of—		Average cost of—		Total gain (-) or loss (+) in weight.

a Calculated from yield of fat in milk.

b Excluding redtop variety, which is not, strictly speaking, a salt hay."

c Total, instead of average.

The cost of milk and butter production is based on the following prices of feeding stuffs: English hay \$18, salt-marsh hay \$10, corn silage \$3.50, wheat bran \$15, and Chicago gluten meal \$20 per ton.

"The salt-hay rations produced from 2 to 5 per cent less milk and butter than did an equal amount of English hay similarly combined. The variety of redtop was the only exception to this; it yielded 9 per cent less milk and butter. . . .

"The salt-hay rations produced milk with a trifle less percentage of fat than did the English hay rations. The difference is so slight as to be of no practical importance.

"Because of the lower market price for salt hays, as compared with English hay, daily rations containing 10 to 12 lbs. of salt hay produced milk and butter from 10 to 20 per cent cheaper than rations containing an equal amount of English hay."

Samples of butter made on English hay, black-grass hay, and fox-grass hay, respectively, were submitted to experts for scoring; and samples of the milk produced on these hays were submitted to different parties.

"These experiments make clear that the salt hays, when constituting from 30 to 40 per cent of the daily ration, did not impart any objectionable odor or flavor to the milk or butter. Flat sage is known to have a somewhat stronger flavor, and had that been fed, it is possible that the results might have been somewhat different."

The effects of food on milk and butter, J. SPEIR (*Trans. Highland and Agr. Soc. Scotland*, 5, ser., 9 (1897), pp. 296-338).—This work, carried on at Newton Farm, Glasgow, was in continuation of experiments¹ made in 1895-96, "which seemed to indicate that two foods, viz, decorticated cotton-seed cake and vetches, had some tendency to increase the fat in the milk, while fresh young grass and grains had a tendency to decrease it. These experiments also plainly indicated that while many foods appeared to have a tendency to enrich or impoverish the milk, still neither effect seemed permanent, the inclination after a time being for the milk to return to more normal conditions."

The present studies were made with 8 cows and covered 12 periods, usually of about 5 weeks each. A large number of feeding stuffs of different kinds were tested in various combinations. The milk was weighed and tested for fat, and was also skimmed with a hand separator and the cream churned and made into butter to observe the effects of the different foods on the production of butter. The general quality of the butter, its melting point, flavor, and keeping quality were also determined. The results are tabulated for each period, together with the results of the previous experiments.

"Rations having an extremely high albuminoid ratio seem to have a depressing effect on the milk yield, well-mixed foods giving the best results in this respect. Every food, when first given, seems to have more or less effect in increasing or decreasing the percentage of fat in the milk. This effect is, however, transitory, and the milk returns to its normal composition about the end of the fifth week. [Brewers'] grains in the wet state and in excessive quantity may be an exception to this general statement.

"Provided extremes are avoided, the dry matter in the food seems to be the principal controlling factor in the production of milk or increase of live weight, and is of greater importance than the albuminoid ratio.

"The fat in the buttermilk is considerably influenced by the food used; but where the cream was churned at the proper temperature, the churnability of the milk appeared to be less affected by food than the experiments of 1895 seemed to indicate. All other things being equal, each food or combination of foods seems to produce a milk which necessitates the cream from it to be churned at a temperature peculiar to itself if the best results are to be obtained.

"Soft butters usually contain a proportion of water greater than the average, and if the softness is caused by the foods used the excess of water can not be reduced by the ordinary methods of manipulation. Food exerts a very great influence on the melting point (firmness) of butter. . . .

"If first-class butter is the object, linseed cake, grains (wet or dry), Paisley meal, and foods containing a large proportion of sugar, should be discarded or reduced to the lowest limits possible.

"The principal concentrated foods experimented with having a beneficial effect on the butter are oats, decorticated cotton cake, beans, and peas."

Feeding fat in the form of an emulsion to milch cows, S. RHODIN (*K. Landt. Akad. Handl.*, 37 (1898), No. 1, pp. 25-33).—Three experiments with 2 cows were made for the purpose of ascertaining the effect of feeding fat to milch cows in the form of an emulsion. Linseed

¹Trans. Highland and Agr. Soc. Scotland, 5, ser., 8 (1896), pp. 269-315).

oil was emulsified in a machine constructed for this special purpose. The fat globules of the emulsion had an average diameter of about 0.0011 mm. and did not separate out on being kept in a closed vessel for 10 months. The oil emulsion was given as a drink in water during 7-day periods, the quantities of oil fed during the different periods ranging from 250 to 750 gm. per day. The rations fed were normal mixed rations, with a nutritive ratio of about 1:5.7. No changes were made in the feed during the different experiments. Experiments 1 (lasting from December 13 to January 16) and 2 (lasting from February 5 to 25) were made with a cow of Strömsholm breed, and experiment 3 (lasting from March 22 to April 11) with a crossbred Ayrshire cow. The main results of the experiments are shown in the table given below:

Results of feeding oil emulsions to milch cows.

Period.	Drinks given in form of—	Experiment 1.				Experiment 2.				Experiment 3.		
		Fat in milk.				Fat in milk.				Fat in milk.		
		Milk yield.	Per cent.	Amount.	Water in milk.	Milk yield.	Per cent.	Amount.	Water in milk.	Milk yield.	Per cent.	Amount.
1	Water	<i>Kg.</i> 13.72	3.50	<i>Gm.</i> 489.6	<i>Per ct.</i> 86.95	9.02	3.68	332.3	86.99	17.33	3.04	527.5
2	Oil emulsion in water	13.12	3.78	495.8	86.82	8.89	3.99	354.8	86.73	17.19	3.24	556.8
3	Do	13.44	3.27	440.0	87.26	9.16	3.63	332.5	86.78	16.33	2.96	482.8
4	Water	13.45	2.75	369.5	87.78							
5	Do	13.76	3.11	428.0	87.42							

The results of the experiments are, briefly stated, that the fat content of the milk was increased at first by feeding large quantities of oil in the form of an emulsion, but later on no increase took place; the milk, on the contrary, dropped to its previous normal fat content, depending on the individuality of the cow.—F. W. WOLL.

Feeding skim milk according to the Trystorp method, P. HANSSON (*Meddel. K. Landtbr. Styr., 1897, No. 42, pp. 150-155*).—In feeding skim milk to cows by this method, it is curdled and straw chaff added to the curdled mass (*E. S. R., 8, p. 248; 10, p. 382*). Instead of adding 75 per cent of chaff, as recommended by the originator of the practice, the author used only 25 per cent. As the result of a feeding experiment with 26 cows, separated into 2 even lots of 13 each, the value of the skim milk was found to be somewhat less than indicated by its content of nutrients, viz, 13 cts. per 100 lbs., against \$1.18 per 100 "food units" of the mixed ration fed. In place of 1.4 lbs. of grain 8.8 lbs. of skim milk was introduced in the ration. The cows did not keep up as well in milk yield or in live weight on the skim-milk ration as they did on the mixed-grain feed.—F. W. WOLL.

Skim-milk feed for milch cows, L. F. NILSON (*K. Landt. Akad. Handl., 37 (1898), No. 2, pp. 115-122*).—A feeding experiment was made with 30 cows to test the merits of the Lindström method of feeding

clabbered skim milk to cows (E. S. R., 8, p. 248). The results of the experiment showed that skim milk fed in this manner was worth not quite one-sixth as much as grain feeds, or less than one-third of what practical experiments seemed to indicate as its value. Valuing 100 kg. of grain feed at \$2.43 (according to Swedish prices), the feeding value of 100 kg. of skim milk was found to be 36.5 cts. This is a somewhat lower relative feeding value for skim milk than was found by Fjord in his early feeding experiments (E. S. R., 5, p. 128), a fact easily explained by the loss of nutrients incident to the preparation of the clabbered milk.—F. W. WOLL.

Spaying cows, J. VENNERHOLM (*Landtmannen*, 9 (1898), No. 23, pp. 363-368).—A general discussion of the subject, with an account of the results of spaying 80 cows at 2 Swedish estates. Four cows had to be killed on account of bleeding, inflammation, etc. Six months after the operation the live weights of the remaining 55 cows had increased from 22,023 kg. before the spaying to 25,111 kg. after, or an average of 156.5 lbs. per head. The milk yield was 532 liters per day before spaying and 507 liters after spaying, or a decrease of about 5 per cent during a little more than half a year.

The writer does not advocate the adoption of this practice on a large scale for healthy animals on account of the possible loss of cows, the small differences in the price of the beef, and finally the uncertainty of increasing or prolonging the lactation of the cows to any appreciable extent.

The paper is further discussed in the same journal (No. 29, pp. 474-476) by R. Arfwedson and the writer.—F. W. WOLL.

The milk supply of Boston and other New England cities, G. M. WHITAKER (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 20, pp. 37, pls. 2, map 1*).—This is an interesting and instructive bulletin on the sources and handling of the milk of several of the larger New England cities, Boston especially. The population of what is termed Greater Boston is given as over 948,000. Three-fourths of the milk supply of this territory is brought in by railroad. A map is given showing the sources of the milk supply of this territory.

"The longest direct run is 140 miles, and some railroad milk comes only 20 miles. Most of this milk is conveyed in cars built for this especial purpose, with refrigerator closets for the cans of milk and with provision for steam heat. . . . Most of the cars start in the morning, from 4 to 6 o'clock, and reach the city between 10 and 11. In a few instances the car starts the afternoon previous, and is on the road over night, reaching Boston during the next forenoon. The cars, in the summer, frequently take the milk of the same morning; some start too early for the milk of that morning, especially in the winter, and hence bring the milk of the previous day. Milk is therefore 18 to 30 hours old before reaching the city. The number of these milk cars averages about 35, although varying somewhat with the season.

"By filling passageways and other open spaces as many as 1,200 cans (10,200 qt.), or over 10 tons in weight, can be got into a car. Railroad officials consider 10 tons a carload. The nominal load, however, is 900 cans (7,650 qt.)."

In the historical discussion it is stated that "Boston seems to have been the pioneer city of the United States in the transportation of milk by railroad," the beginning having been made in April, 1838.

"To-day the business of transporting milk to the city by railroad is done by 7 concerns. Six of these 7 milk wholesaling houses have an association for bringing about uniformity in methods of doing business and for mutual self-protection. To-day fully three-quarters of the milk supply of Greater Boston passes through the hands of these large wholesalers, locally known as 'contractors.' . . ."

"All of the contractors have cheese or butter factories in the city or country, or both, for the manufacture of butter and cheese."

The arrangements between the milk producers and the contractors are described, and also the Milk Producers' Union, which is an organization of the farmers who sell milk to the contractors. This union deals with the Milk Contractors' Association in fixing the schedule of prices and other regulations, and has tended to promote uniformity and business-like methods and to keep the price of milk quite steady. The summer and winter prices for 12 years are given, showing remarkably little variation. The average "theoretical Boston price per can of 8½ qt." for 12 years has been 32¼ cts. during summer and 36¾ cts. during winter. From this "theoretical" price a deduction is made for transportation on a fixed schedule agreed to by the Milk Producers' Union, depending upon the distance. There is also a deduction made for the surplus milk, which is made into butter, and for which only the "butter value" of the milk for the month is paid. This, together with "grading" the price in different months to prevent too large a surplus, is a cause of much friction between the producers and the contractors, as the application of the system is blind to many farmers. But the system of buying all the milk that is offered furnishes shippers a market for all they can produce and does away with the former inconvenience arising from the irregularity of the amount taken by the contractors.

"The cans are returned to the farmers unwashed and sometimes in a very filthy condition," which has gone so far as to result in several attempts on the part of the farmers to invoke legislation compelling the contractors to wash the cans.

Of the other one-fourth of the milk supply a portion comes in by railroad and the remainder is produced within the limits of Greater Boston or in territory nearby. "Over 7,000 cows are kept in Greater Boston."

The milk supply of Providence, the second city in size in New England, is nearly all produced within 20 miles of the city. About 75,000 qt. per day, or 27,375,000 qt. per year, is used.

"The selling of milk from stores is more prevalent than in many other cities of New England. It is estimated that almost half of the milk consumed in this city is sold from stores instead of being delivered from house to house by peddlers. . . . Milk is from 12 to 48 hours old when it reaches the consumers in Providence."

The supplies of several other cities are briefly noted, although for the most part they present no novel features.

The cream trade, which has largely increased of late, is described, together with the sale of skim milk, buttermilk, condensed milk, etc. The rather surprising statement is made that although a great deal of surplus milk is made into butter after it reaches Boston, furnishing quite a large supply of skim milk, the greater part of it is allowed to run into the sewers, as there is no market for it.

The milk laws and inspection are discussed, together with a consideration of the quality of milk sold in different cities.

"All of the States have laws relative to the healthfulness of the milk supply. Massachusetts, Maine, Rhode Island, and New Hampshire prohibit the sale of milk from sick or diseased cows or cows fed upon the refuse of breweries or distilleries or upon any substance deleterious to its quality. Connecticut prohibits the sale of 'impure milk' and milk from cows which shall have been adjudged by the commission upon diseases of domestic animals to be affected with tuberculosis or other blood disease. A Massachusetts law imposes a fine upon 'whoever knowingly feeds or has in his possession with intent to feed to any milch cow any garbage, refuse, or offal collected by any city or town.' There is, however, no especial sanitary inspection of milk and its sources in any New England town or city. . . .

"Local boards of health, however, have considerable authority, and in several cases they have issued orders or made regulations in advance of the average practice of the State."

The germs in milk; studies of foremilk of cows, J. NELSON (*New Jersey Stat. Rept. 1897, pp. 195-223*).—The following is the author's summary of his work in these lines:

"*Studies of the germs of milk, quantitatively considered, relative to the sources of contamination.*—Gelatin cultures were made from milk as freshly drawn from the cow, and the number of bacterial colonies developing were counted; then the increase in the germ content during cooling was determined; next, the increase due to the process of bottling. It was found that the germs multiply during the time elapsing before the milk is cooled, and that the various utensils with which the milk comes in contact during handling, cooling, bottling, etc., each contributes its quota of germ contamination, so that the germ content of the milk at the time it is placed in cold storage, within an hour after milking, is already 10 times as great as at first. The principal source of contamination was found to be the valves of the bottling machine. The first milk passing undergoes a doubling in its germ content.

"As an appendix to this section, the use of the [Star] cooler as a pasteurizing apparatus is considered. Steam is turned through the 'cooler' in place of cold water, and the resultant temperature of the milk is 150° F. Germ cultures showed a decrease in germ content of 0.95 under the crudest conditions and immediate cooling. Thus it appears as if this method could, with slight improvements, become successful and practicable.

"*Studies of the foremilk of cows.*—The first milk drawn from the udder, with aseptic precautions, was observed macroscopically. The different spurts were kept in separate tubes, and from each teat of each cow 3 different samples were prepared. The time elapsing before acidity developed and subsequent clotting was noted, and to aid in this determination the milk was colored with litmus from the start. A most complex variety of results was obtained, whose import can not be shown until the various germs producing the changes have been isolated and studied in pure cultures. The practical aim in this work is the development of a method of milk analysis which shall be expeditious, and shall give an idea of the quality of the bacterial flora which the individual cow favors and harbors in her udder. This has

two important bearings: On the one hand it will throw light on such diseases as garget, and on the other hand will show the keeping qualities of the milk, and the sort of butter or cheese it will produce. These are all-important considerations in respect to the characteristics of a good dairy cow."

Swedish butter exhibitions during 1897, N. ENGSTRÖM (*Tidskr. Landtmän*, 18 (1897), No. 51, pp. 920-929; *Nord. Mejeri Tidn.*, 12 (1898), No. 51, pp. 604, 605; 52, pp. 617-619; 53, p. 630).—During the year 317 creameries exhibited 1,214 tubs of butter. The average score was 11.1 (on a total of 15 points), 44 per cent of the tubs scoring over 12 points. The average results for the year are shown in the following tables:

Swedish butter exhibitions, 1897.

Class of creamery.	Number of tubs.	Maximum score.	Percentage scoring above 12 points.	Average score.	Average water content.	Percentage containing above 15 per cent water.
				<i>Points.</i>	<i>Per cent.</i>	
Cooperative.....	477	14.2	56.0	11.5	13.2	4.0
Estate.....	316	13.8	36.7	10.9	13.5	8.9
Estate-proprietary.....	215	13.7	39.5	11.0	13.6	12.0
Proprietary.....	206	13.7	32.0	10.6	13.8	18.4
Average.....	1,214	14.2	44.0	11.1	13.4	9.2

Of the tubs exhibited, 1.7 per cent lost brine during storage, the average amount per tub being 0.45 lb., maximum amount, 1.68 lbs. There has been a uniform improvement in the average quality of the butter exhibited during the 4 years since the butter exhibitions were established.—F. W. WOLL.

Milk and dairy products, F. STOHMANN (*Milch- und Molkeerzeugnisse: Ein Handbuch für Milchtechniker und Nahrungsmittelchemiker. Braunschweig: Friederich Vieweg & Sohn, 1898, pp. XXIX + 1031, figs. 235*).—This extensive treatise, which was issued a few months after the author's death, brings the literature of the subject down to within the last 2 or 3 years. In its scope it covers the whole field of the chemistry and properties of milk, the analysis of milk and dairy products, dairy bacteriology, and the utilization of milk in different ways, as in its original form, for butter making, cheese making, making of condensed milk, kommiss, kephir, etc. Although naturally devoted largely to cows' milk and its products, the milk of different kinds of animals and the products manufactured from it are included, with a discussion of the manufacture of oleomargarine, the recognition of oleomargarine and filled cheese, and the detection of these and other forms of adulteration.

Throughout the entire book the discussion is based upon the results of scientific investigations and experiments, and their application in practice is pointed out in a clear and concise manner. The production of milk, or what may be termed dairy farming, is not entered into at any length, although the effect of various methods of feeding and treatment of cows on the yield and composition of the milk and the specific effects of a large number of feeding stuffs on the quality of milk and dairy products are considered quite fully. The various operations in the creamery and cheese factory and in the handling of milk are treated at length, with illustrated descriptions of various forms of machinery and apparatus.

Altogether the book forms the most comprehensive treatise on the subject from a scientific standpoint that has been issued. The numerous references given in footnotes are a valuable feature. The method of treatment is such as to make the book

interesting and useful to educated dairymen. An unusually detailed table of contents and a comprehensive alphabetical index contribute to make the book a most valuable work of reference.

The development of the dairy cow, C. D. SMITH (*Indiana State Dairy Assoc. Rpt. 1897*, pp. 98-111).—A historical account, with descriptions of some of the famous dairy cows.

The factors essential to secure profit in the dairy, C. D. SMITH (*Indiana State Dairy Assoc. Rpt. 1897*, pp. 133-137).—Special stress is laid upon the care of the dairy cow.

The cost of production, T. L. HAECKER (*Indiana State Dairy Assoc. Rpt. 1897*, pp. 83-98, figs. 5).—An address based upon the author's experience with the herd of the Minnesota Station.

Yields of Norwegian dairy herds, K. DÖHLEN and A. KJÖLSTAD (*Norsk Landmansblad, 17 (1898), No. 8, pp. 81-84; 11, pp. 112, 113*).—The live weight of the herd of Smaaleus cattle at Kalnäs agricultural school ranges from 670 to 1,000 lbs. and averages about 800 lbs. The average milk yield of 10 cows kept in the barn throughout the year was 5,640 lbs., with an average fat content of 3.7 per cent.

Yield of herd of Oestland cattle at Frogner, 1897, A. KJÖLSTAD.—A herd of 14 head of Oestland cows at Frogner, with an average age of $7\frac{1}{2}$ years, and an average live weight of 865 lbs., gave an average yield of 4,900 lbs. of milk in 1897, with a fat content of 3.72 per cent.—F. W. WOLL.

The college herd, F. W. MORSE (*New Hampshire Sta. Bul. 48, pp. 120, 121*).—Brief statistics are given on the milk production of the college herd.

“Making no deductions, the herd has been equivalent to 284 milch cows and 51 dry cows for 1 month, and has produced 145,019 lbs. of milk and 7,875 lbs. of butter, making the average monthly yield per head for 335 cows, 23.5 lbs. of butter and 24 cans of milk, or 282 lbs. of butter and 288 cans of milk per year.

“The only allowance to which attention is called is the fact that one-fifth of the herd's equivalent has consisted of heifers in their first lactation period.”

Book of German cattle, RAMM and PAREY (*Deutsches Rinder-Merkbuch. Berlin: Paul Parey, 1898, pp. 129, figs. 102, col. pls. 8*).—Illustrated description of notable cows, bulls, and oxen of different breeds.

The feeding of milch cows, E. O. ARENANDER (*Nord. Mejeri. Tidn., 13 (1898), No. 16, pp. 212-214; 17, pp. 223, 224*).

Reindeer moss for milch cows, B. TORSSELL (*Meddel. K. Landtbr. Styr., 1897, No. 42, pp. 172, 173*).—The moss was found of no greater value for milch cows than is indicated by the chemical analysis, viz, about the same as straw-chaff.

The estimation of fat in condensed milk by the Gerber milk test, N. GERBER and M. M. CRAANDIJK (*Milch Ztg., 27 (1898), No. 39, pp. 611-613*).—The results of numerous determinations by this method are compared with gravimetric analysis. A weighed quantity of the condensed milk is diluted, and then treated similarly to ordinary milk, except that it must be heated longer and whirled longer in the centrifugal.

Extracts from the annual report of the chemical laboratory of the city of Altona, A. REINSCH (*Milch Ztg., 27 (1898), No. 31, pp. 484, 485*).—Relates to the results of examinations of butter, rancid butter, margarin, milk, and milk preparations.

Municipal control of dairies in Indiana, A. W. BITTING (*Indiana State Dairy Assoc. Rpt. 1897, pp. 147-152*).—A paper pointing out the advantages of dairy inspection.

Experience in preparing sanitary milk, B. C. COX (*Indiana State Dairy Assoc. Rpt. 1897, pp. 36-40*).—An account of the methods employed by the author.

Police supervision of the milk supply of Geneva, E. A. ACKERMANN (*Milch Ztg., 27 (1898), No. 29, p. 496*).—A summary of the results of the milk control.

The adulteration of dairy produce, R. HEDGERWALLACE (*Edinburg: C. & R. Anderson, 1898, pp. 89*).—This is a quite general paper, read before the Royal Scottish

Society of Arts. It treats of the local supply and the importation of dairy products, the forms of adulteration practiced, and the legislation on this point in various countries.

Note on the volume concentration of condensed milk, A. MCGILL (*Analyst*, 23 (1898), May, pp. 128, 129).

Shipment of frozen milk (*Milch Ztg.*, 27 (1898), No. 36, p. 568).—Fifty liters of milk were sent from an "ice dairy" in northern Prussia to Zurich June 1. It was contained in a square can packed in a wooden box with straw, and was sent by fast freight, but owing to delays at the custom-house was not received for testing in Zurich until June 9. Its temperature when opened was 7° C. It was entirely normal in taste and smell, and showed an acidity of 3.4 by the Soxhlet-Henkel method, which is said to correspond to the acidity of normal milk as it comes from the cow. The milk was, therefore, perfectly sweet and unchanged after being 9 days in transport, which is an indication of what can be done in sending milk cooled to freezing. The dairy from which it was sent will, it is stated, send 10,000 liters of cooled or frozen milk daily to Berlin, and guarantee to deliver it sweet to consumers. A similar establishment is in successful operation in Copenhagen.

Armenian mazon, O. EMMERLING (*Centbl. Bakt. u. Par.*, 2. Abt., 4 (1898), No. 10, pp. 418-420).—Mazon is an Armenian drink similar to kephir. Two bacteria have been isolated, one a micrococcus, the other a bacillus which is thought identical with *Bacillus acidi lactici*.

Experiments with Pfeiff's pasteurization apparatus, N. ENGSTRÖM (*Tidskr. Landtmän*, 19 (1898), No. 14, pp. 237-242).—The results show the apparatus to be of doubtful value, the product obtained being of inferior quality, and its capacity being small and decreasing as the pasteurization progresses.

On the importance of pasteurization in dairying, A. V. SCHRADER (*Biet*, 19 (1898), No. 4, pp. 101-108).

A survey of the creamery situation in Indiana, C. S. PLUMB (*Indiana State Dairy Assoc. Rpt.* 1897, pp. 164-174).—An account of the development and extent of the creamery system in Indiana, with statistics.

Experiment with the Alpha churn No. 3, KLEIN (*Milch Ztg.*, 27 (1898), No. 29, pp. 454-456).—Experiments with this churn on cream of different degrees of acidity at different temperatures, etc.

Effect of the salt on the taste of butter (*Milch Ztg.*, 27 (1898), No. 38, p. 601).—The Chamber of Agriculture for the Province of Posen has called attention to the fact that the salt used in creameries contains as high as 0.6 per cent of magnesium sulphate, and that this amount imparts a bitter taste to butter. Accordingly the Chamber of Commerce proposes to supply salt which has been tested and found to contain under 0.025 per cent of magnesium sulphate.

The butter-producing capacity of cows' milk can be increased by proper selection of breeding stock, H. BRANDT (*Landmansblade*, 31 (1898), No. 11, pp. 139, 140).—Summary of the results of 10 years' work by a practical farmer.

Cheese from pasteurized milk, J. A. ANDRÉ (*Landtmannen*, 9 (1898), No. 25, pp. 403, 404).—The cheese is manufactured from a mixture of 10 per cent buttermilk, 25 to 50 per cent unpasteurized milk, and the rest pasteurized milk. The product is said to be of prime quality.

In No. 31 of the same journal (p. 504), a method of making cheese from pasteurized milk mixed with 5 per cent of buttermilk is given. [In both cases the cheese is evidently made from skim milk.]—F. W. WOLL.

The manufacture of Grana cheese, G. BILLITZ (*Milch Ztg.*, 27 (1898), No. 33, pp. 609-611).—The results of experiments are reported.

Dairy experiments conducted at Mustiala experiment station, 1894-95, R. GRIPENBERG (*Meddel. K. Landtbr. Styrs.*, 1897, No. 20, pp. 34-57).—Reports are given of experiments with the Radiator, feeding experiments with cows of Ayrshire-Finnish and native Finnish breeds, trials of milk antiseptics, experiments with

Babeock and Gerber milk testers, trials with the Alpha-Colibri separator, feeding experiments with caraway hay for milch cows, and titration of sour cream.—F. W. WOLL.

Report of the [Massachusetts] dairy bureau, G. M. WHITAKER (*Agr. Massachusetts, 1897, pp. 281-303*).—This relates to the sale of oleomargarine, inspection of milk and milk supply of Boston, and gives general information relative to the dairy industry in the State.

VETERINARY SCIENCE AND PRACTICE.

Observations on the experiment cows with reference to tuberculosis, J. NELSON (*New Jersey Stat. Rpt. 1897, pp. 221-240*).—This portion of the author's report consists of a description of autopsies and of temperature tests.

"The members of the experiment herd have now been injected with tuberculin from 15 to 17 times within 3 or 4 years. In general, the results agree with the conclusions published in previous reports. Repeated injection of tuberculin does not seem to exert any decided influence, either for increase or for cure of tuberculosis of slightly tuberculous animals. The results in some cases appear to point in one direction and in others in the opposite direction, but in neither case so decidedly as to be of practical import. In some cows the reaction which tuberculin causes is entirely suppressed by repetition of injection, and in others it is only temporarily suppressed."

Cornstalk disease, A. T. PETERS (*Nebraska Sta. Bul. 52, pp. 51-62*).—The cornstalk disease of cattle and horses is described and the various theories which have been advanced as to its cause are discussed, the opinions of many investigators being quoted. Circulars requesting information concerning the prevalence of cornstalk disease in Nebraska were sent out, and the replies received are summarized.

"From the data gathered from these few letters and from past experience it is known that a great many cattle succumb to this disease. These further show that there is a great difference in the time that animals are in the fields before the first death occurs. It is also clearly shown that the stockmen have found a remedy in feeding a grain ration and not allowing stock to feed on cornstalks alone."

The prevalence, symptoms, and treatment of milk fever, garget, and abortion, J. NELSON (*New Jersey Stat. Rpt. 1897, pp. 241-260*).—The occurrence of milk fever and abortion in the college herd led the author to study these diseases and garget. A circular letter was sent to numerous localities in the State requesting information on the prevalence of these diseases in dairy herds and concerning the remedies employed, including the use of disinfectants.

Replies indicate that 64 herds were affected with milk fever, 70 with garget, and over 90 with abortion. In 25 of the herds abortion had prevailed to an extent ranging from 20 to 100 per cent. The symptoms, cause, and treatment of milk fever and garget are described. The reports received indicate that about 150 cows were affected with the former disease and that the majority died. During the past 4 years this disease has become less prevalent than formerly.

About 150 cases of garget are reported. Bovine abortion is discussed

at considerable length and the fact is noted that the disease is becoming less common, owing in part to the application of antiseptic methods of treatment. The primary cause of abortion is considered to be a specific germ, though it is noted that various other causes may also produce it.

The subject of immunity, contagiousness, modes of infection and treatment, antiseptics and disinfectants are briefly treated. The method of securing immunity by the first infection is not thought recommendable for the general practice since a considerable portion of the cows affected with abortion become sterile. The antiseptics and disinfectants noted are corrosive sublimate 0.1 of 1 per cent for general use; as, on the floor, full strength; for sponging the vulva, one-half strength; for injection, one-fourth strength; and for uterine irrigation, one-eighth strength. It is improved by an addition of 10 parts of salt; for irrigation purposes, by adding a mixture of glycerin and alcohol, 3 parts, or, for sponging, by an addition of one-fourth oz. of hydrochloric acid to 1 gal. of solution. Sulphate solution, consisting of 17 grains of copper sulphate to each ounce of water, or 3 lbs. iron sulphate to 30 gal., to be used in watering barn floors weekly; sulphuric acid 2 per cent, for barn floors; chlorid of lime, air-slaked lime, or land plaster for litter or manure; a carbolic acid mixture, consisting of 1 part carbolic acid, 2 of sodium carbonate, in 100 parts of water to be used for disinfecting the penis and for vaginal injection before service; and creolin, which is considered to be the best. It may be used for uterine irrigation in a one-half to 1 per cent strength or for vaginal injection in from 1 to 2 per cent strength; for sponging, 2 to 3 per cent strength, or for general disinfection of a barn as high as 4 per cent.

Tuberculosis of animals, E. NOCARD (*Les tuberculoses animales*. Paris: Masson, 1898. *Encyclopédie scientifique des Aide-Mémoire*. Rev. in *Jour. Hyg.*, 23 (1898), No. 1143, pp. 395, 396).

Bovine tuberculosis, M. A. O'CALLAGHAN (*Agr. Gaz. New South Wales*, 9 (1898), No. 8, pp. 837-849, pls. 3).—The possibility of diminishing bovine tuberculosis is discussed and the results of the author's observations along this line are briefly noted, as well as the use of the tuberculin test. The need of experiments under Australian conditions is pointed out.

Rendering animals immune to a mixture of diphtheria bacilli and streptococci, J. BERNHEIM (*Arch. Hyg.*, 33 (1898), No. 1-2, pp. 35-69).

On the relation between the excretion of nitrogen in the metabolism of a horse and the production of diphtheria serum, G. MARENGHI (*Centbl. Bakt. u. Par.*, 1. Abt., 21 (1897), No. 6-7, pp. 256-261).—Experiments in which the nitrogen in the urine was determined were made with horses used for the production of diphtheria antitoxin. These are briefly reported, the following conclusions being drawn: Antitoxin serum is formed from materials furnished by the blood. Its formation is closely connected with biochemical processes which are evidenced by an increase in

the total nitrogen and urea nitrogen of the urine. The nitrogen introduced in the diphtheria virus is not sufficient to account for the excess. The change in the nitrogen content of the urine takes place very quickly. The animal organism takes an active part in the formation of this serum, even if this is not shown by fever or any local reaction. The blood retains the antitoxic properties for only a short time after the injections of diphtheria virus cease, and sometimes lose such properties even if the injections are continued.

Septicæmia in geese due to spirochate, GABRITSCHEROSKI (*Ztschr. Medicinal-beamte*, 1898, 13; *abs. in Ztschr. Fliesch u. Milchhyg.*, 9 (1898), No. 1, pp. 12-13).

Infectious pneumonia of sheep, W. R. DAVIS (*Vet. Jour.*, 1898, Apr., pp. 233-235).

The Croonian lectures on the chemical products of pathogenic bacteria considered with special reference to enteric fever, W. MARTIN (*British Med. Jour.*, 1898, No. 1955, pp. 1569-1572; 1956, 1644-1646).

Micro-organisms and bacterial poisons in brain and spinal cord, J. SIETZ (*Arch. Path. Anat. u. Physiol. [Virchow]*, 150 (1897), No. 1, pp. 33-51).

Etiology of epizootic abortion, S. J. J. HARGER (*Jour. Comp. Med.*, 1898, No. 1, pp. 226-231).

The prevalence, cause, and treatment of bovine abortion, milk fever, and garget, J. NELSON (*New Jersey Stat. Bul.* 127, pp. 24).—A reprint from the Annual Report of the station for 1897 (see p. 494), with the addition of a bibliography of recent literature on the subject.

A new Trichophyton which produces herpes in horses, MATRUCHOT and DASSOUVILLE (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 5, pp. 279-281).—The authors describe an outbreak of this disease among the horses of the Twelfth Artillery. The cause is said to be a new Trichophyta. Its appearance and growth on various culture media are described, and the successful inoculation of the disease on man and on guinea pigs.

Aphtha or vesicular stomatitidis of the horse, D. HUTCHISON (*Vet. Jour.*, 1898, July, pp. 54-56).

Ankylostomiasis of horses, S. VON RÁTZ (*Centbl. Bakt. u. Par., 1. Abt.*, 24 (1898), No. 8, pp. 289-305).

Botryomykosis in man and animals, SCHNEIDEMÜHL (*Centbl. Bakt. u. Par., 1. Abt.*, 24 (1898), No. 6-7, pp. 271-277).—This article includes an address before the Physiological Society of Kiel.

Trichinæ: German inspection of American hog products, J. A. BARNES (*U. S. Consular Rpts.*, 1898, No. 217, pp. 200-203).—The rigid laws regarding American meat imported into Germany are discussed, as well as the possibilities of the importation into Germany through Belgium of uninspected meats.

The symptomology of animal parasites, PEIPER (*Deut. Med. Wchnschr.*, 23 (1897), No. 48; *abs. in Centbl. Bakt. u. Par., 1. Abt.*, 23 (1898), No. 24, pp. 1064, 1065).

Zamia poisoning, A. W. V. CRAWLEY (*Producers' Gaz. and Settlers' Rec. [West. Australia]*, 5 (1898), No. 5, pp. 399-402).—Notes are given on the effect and treatment of zamia poisoning in cattle. The symptoms of poisoning, post-mortem appearance, and methods of treatment are given in some detail. According to the author, zamia acts as a cumulative poison, and cattle were probably encouraged to eat it on account of other feed being scanty and dry. Attempts are being made to ascertain the active principle or alkaloid causing the poisoning, and it is suggested that if possible all such plants should be eradicated from pastures.

STATISTICS.

Index to volumes 21 to 50, Die Landwirtschaftlichen Versuchs-Stationen, F. NOBBE and L. HULTNER (*Landw. Vers. Stat., 50 (1898), Sup., pp. 1-193*).—Author and subject indexes to the contents of the last 30 volumes of this journal.

Dairy experiment station of the Chamber of Agriculture of the Province of Schleswig-Holstein at Kiel, R. EICHLORF (*Milch Ztg., 27 (1898), No. 27, pp. 420-423, figs. 4*).—An illustrated description of the buildings, with ground plans; the organization, work of the station, etc.

Fourth report of progress on extension work, I. P. ROBERTS (*New York Cornell Sta. Bul. 146, pp. 633-654, maps 3*).—This bulletin deals with the progress of the State extension work in agriculture. Part I contains the reports of the various departments concerned in investigational work; Part II deals with the educational work. During the period May, 1897, to February, 1898, more than 700 lessons and lectures have been given throughout the State; 30,000 teachers and 16,000 school children have been sent leaflets on nature study, and 2,500 young farmers have been enrolled in the agricultural reading course. Previous reports of extension work have been given in Bulletins 110, 122, and 137 of the station (E. S. R., 8, pp. 135, 740; 9, p. 699).

Report of the director of New York State Station, W. H. JORDAN (*New York State Sta. Bul. 142, pp. 721-740*).—A comprehensive review of the work of the different departments of the station during the year, giving results in some instances, with a list of the bulletins published in 1897.

Annual Report of Oklahoma Station, 1898 (*Oklahoma Sta. Rpt. 1898, pp. 4*).—A report on the personnel, equipment, and outline of work of the station, with a list of bulletins issued during the year and a financial statement for the fiscal year ending June 30, 1898.

Ninth Annual Report of New Hampshire Station, 1897 (*New Hampshire Sta. Bul. 48, pp. 116-149, figs. 15, map 1*).—This contains a financial statement for the fiscal year ending June 30, 1897; a report of the vice-director, and reports of the agriculturist and horticulturist, entomologist, bacteriologist, and meteorologist, noted elsewhere.

Annual Report of New Jersey Stations, 1897 (*New Jersey Stas. Rpt. 1897, pp. XIX + 536, figs. 71, pls. 11, dym. 1*).—This contains a financial statement of the State Station for the year ending October 31, 1897, and of the college station for the fiscal year ending June 30, 1897; a report of the director reviewing the work of the different departments for the year, and reports of the chemists, assistant in horticulture, assistant in dairy husbandry, biologist, botanist, and entomologist, noted elsewhere.

NOTES.

IDAHO UNIVERSITY AND STATION.—Herbert T. Coudon has been elected registrar and accountant of the university and station.

MICHIGAN STATION.—The average yield of sugar beets on the station grounds is 12.93 tons per acre; the average percentage of sugar, 13.72. The results of cooperative experiments are being worked out. The factory at Bay City is in successful operation, with 3,000 acres of beets to work up. Experiments to test the value of beet pulp for cows, beef cattle, and sheep are planned for next winter. The year's record with a grade dairy herd of 29 cows has been completed. The average milk yield of the cows, rejecting one accidentally injured and another condemned as tuberculous, was 7,008 lbs. The fat yield averaged 257.57 lbs. The net profit from the herd, including in the expenses the cost of the care and milking as well as the food, but not crediting the value of the 200 tons of manure made, was \$277.59.

NEW YORK STATE STATION.—Firman Thompson, assistant chemist at the station, has resigned his position to accept an appointment under Dr. Walter Maxwell at the Hawaiian Experiment Station and Laboratories. H. A. Harding, bacteriologist of the station, assumed active duty January 1, 1899.

VERMONT STATION.—At the recent session of the legislature of Vermont three bills were passed which affect and add to the work of the station. (1) A bill appropriating \$1,000 annually toward the printing of the station report; (2) a bill regulating the sale of concentrated commercial feeding stuffs, being similar in its nature to the law which has been in force for something over a year in the State of Maine; (3) a bill requiring that the correctness of all Babcock glassware in use at creameries and cheese factories for dividend making shall be certified, and that all operators of the Babcock test for dividend making shall be duly licensed, the licenses to be issued upon demonstration of their ability properly to operate the test. The execution of the latter law is placed in the hands of the superintendent of the dairy school.

PERSONAL.—In connection with the death of the late Col. George E. Waring, jr., formerly commissioner of street cleaning in New York City, it is interesting to note his interest in agriculture and his services and writings during his earlier life. As early as 1853 Colonel Waring studied scientific agriculture under Dr. James J. Mapes, one of the pioneer agricultural chemists of the country, and in 1855 he assumed the management of Horace Greeley's famous farm at Chappaqua, New York. After the civil war he removed to Newport, Rhode Island, where for 10 years he had charge of the Ogden farm, and during this time wrote the interesting Ogden Farm Papers for the *American Agriculturist*. In 1868 he originated the American Jersey Cattle Club, the first American association of its kind to publish its own herd book, of which he was the secretary and editor of the Herd Book until 1882. In 1870 he introduced the Trophy tomato, which marked the beginning of the successful production of the tomato for shipping and canning. He traveled through Holland, Normandy, Brittany, and the Channel Islands studying the agriculture of these countries, and as a result introduced into this country the Swartz system of cold deep setting of milk, which was the forerunner of the present systems of deep setting. Among his published agricultural works are the following: *Elements of Agriculture* (1854), *Drainage for Profit and Drainage for Health* (1868), *The Handy Book of Husbandry* (1869), *The Sanitary Draining of Houses and Farms* (1874), *A Farmer's Vacation: Travels in Holland, Normandy, Brittany, and the Channel Islands* (1875), *Sewage and Land Drainage* (1889), and *Modern Methods of Sewage Disposal* (1891).

AGRICULTURAL EDUCATION IN RUSSIA.—The Government of Russia is planning for the establishment of a quite extensive system of agricultural education. At a recent meeting of the agricultural council, an advisory body of which the minister of agriculture is chairman, an outline presented by the minister was considered at length and a general plan of agricultural education was elaborated. The introductory to this document states that notwithstanding the fundamental importance of agriculture to Russia and the great fertility of some of the Russian soils, "the crops obtained even on the chernozem (black soil) are only one-third to one-half as large as those harvested from the incomparably inferior soils of Western Europe. Almost everywhere in Russia the primitive processes of farming are persistently followed by the farmers, while the number of persons who are fitted by education and training to disseminate information on the rational methods of agriculture is comparatively insignificant." The scheme outlined provides for (1) higher education, furnished by independent agricultural institutes located in the chief agricultural zones of Russia, and by chairs of agriculture and allied sciences in the universities; (2) agricultural high schools, which are in the nature of technical schools and schools with courses in agriculture; (3) lower agricultural schools; and (4) the diffusion of general agricultural information. The schools for the so-called lower education include (a) secondary agricultural schools, (b) primary agricultural schools, (c) agricultural classes, and (d) practical agricultural courses. These lower schools are to be under the jurisdiction of the minister of agricultural and imperial domains. They are to be maintained at the expense of municipalities, local communities, associations, etc., but may receive a part of their support from the Government. They are to have the franking privilege for official mail matter and packages not exceeding 36 lbs. in weight. The secondary schools are to be established on government land or land donated for that purpose. The other lower agricultural schools may be established on private estates. The secondary schools are open to young men of all conditions who have completed the course in the primary public schools. The course of instruction covers 4 years, and includes in addition to the general studies the elements of the natural sciences, agricultural and rural economy, cattle raising, veterinary, agricultural law, horticulture, gardening, etc., together with carpentry and blacksmithing in their application to agricultural machinery. The primary agricultural schools are open to all who can read and write and have a knowledge of arithmetic as far as fractions. The courses last from 1 to 3 years. They include, aside from general studies, instruction in the elements of agriculture, with practical exercises. The classes in agriculture are intended for the instruction of young men of the peasant class. The course does not last longer than 2 years, and consists in the study of the rudimentary principles of agriculture and their application to the local conditions. The successful completion of the courses in these 3 grades of the lower agricultural schools carries with it certain reductions in the military requirements, dependent upon the grade. The practical agricultural courses are designed to impart popular information in particular branches of agriculture. The instruction does not continue for more than a year, and consists in demonstrations, talks, and practical exercises in different branches of agriculture in their application to local conditions, and especially to the conditions of the peasants. The diffusion of general agricultural information is to be provided for by (1) the organization of public readings or lectures on agricultural questions for the benefit of different classes of the population, (2) instruction of the teachers in the public schools in agriculture, horticulture, gardening, apiculture, etc., and providing the public schools with small plats of land and means for cultivating the same, (3) the teaching of agriculture in the normal schools, and (4) the introduction of supplementary courses in agriculture in the village schools. There are now in Russia 3 schools for higher agricultural instruction, 9 agricultural high schools, 83 lower schools, and 59 special courses. Steps have already been taken for the establishment of about 50 additional agricultural schools.

EXPERIMENT STATION RECORD.

VOL. X.

No. 6.

Among the many important services which the late Senator Justin S. Morrill rendered to his country during his long and honorable career as a member of Congress none so justly entitle him to lasting remembrance as a benefactor of mankind as those by which he became a potent factor in the advancement of science and education in every State and Territory of the Union. Growing up under the thoroughly democratic conditions existing in rural New England in the earlier half of this century, and coming to Congress in the prime of life after a successful experience as a business man and a farmer, his mind opened readily to receive the new ideas regarding education in the arts and sciences which were then being actively discussed by the leaders of public opinion in this country and abroad. The conditions which gave rise to this agitation have been thus described by Prof. W. H. Brewer, who has himself been closely identified with the great movement in which Senator Morrill performed such distinguished services:

“The period between 1840 and 1860 was a peculiar one in the history of the world’s intellectual activity and material progress. At its beginning some of the physical sciences, more particularly chemistry and geology, were scarcely 50 years old, but they had already revolutionized some of the arts and produced great changes in agriculture. All this had taken place within the lifetime of the older workers then in the field. Popular works on science were widely read, and had prepared the public mind to cherish hopes, perhaps exaggerated, of the benefits to come by the applications of science, and had greatly stimulated intellectual activity in this new field of knowledge. . . .

“In a thousand and one ways, more in the other lines than in agriculture, discovery, invention, and the application of scientific laws to the arts and industries were playing a part in the development of the material resources of the civilized world and modifying the industries and occupations of men. There was then an absorbing interest in the growing steam transportation; railroads and ocean steamships then came into use and were made practicable; iron working, dyeing, and many other arts were being revolutionized by chemistry; commercial fertilizers were coming to be used; the electric telegraph, just invented, first came into use during this period; other events, some of them political, were

profoundly affecting the current of human activity; prices, which had been falling from the decline of the production of silver in Mexico, began to rise with the discovery and production of gold in California. This was the beginning of an era in the rise of prices and of material prosperity unexampled in the history of civilization. . . .

“All these influences produced a deep and lasting effect on the theories and practice of education. The ‘old education,’ as it was called, did not supply the new wants. There was a loud and discordant demand for something else. The many agreed only in this, that less Latin and Greek (which had before been considered the corner stone and substance of a liberal education) be taught and in their place more science; or at least that, whatever place the old college curriculum might have in the future, new systems of education were required in this new development of civilization. . . . This discussion, along with that of elective studies instead of a rigid curriculum, went on in all the colleges and universities in the land. The University of Virginia already had elective courses. All tried in some way to expand in the direction of the physical sciences. . . . Going along with these changes in collegiate instruction there was much clamor for purely technical schools of special kinds. In no direction was this more marked than in agriculture.”

As attempts to establish scientific and technical schools in the several States increased in number and public interest in this matter grew apace, the attention of Congress was naturally drawn to this subject, but it was not until the movement for securing national aid for such institutions found in Mr. Morrill an active, wise, and persistent leader in shaping and directing legislation on its behalf that success was attained. The records of Congress show that only a man thoroughly persuaded of the importance and wisdom of this great enterprise would have persevered as Mr. Morrill did in the face of much misunderstanding and opposition until the desired end was finally attained.

On December 14, 1857, Mr. Morrill, then a Member of the House of Representatives, introduced a bill authorizing the establishment of industrial colleges in every State and granting for their maintenance 20,000 acres of the public land for each Member of Congress. This bill was referred to the Committee on Public Lands, which brought in an adverse report April 15, 1858. Nevertheless in the following session of Congress the bill passed both Houses, but it was vetoed by President Buchanan. The only effect of this serious rebuff on Mr. Morrill was to lead him to broaden the scope of the measure, and in December, 1861, he introduced an amended bill which bestowed 30,000 acres of land for each Member of Congress upon the several States for the establishment of colleges “where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts, in order to promote the liberal and practical education

of the industrial classes in the several pursuits and professions in life." After several months this bill was also reported on adversely by the Committee on Public Lands, but in the meantime it had been introduced in the Senate, where it passed on June 10, and a few days later was taken up and passed by the House and received the approval of President Lincoln. This act had been drawn on broad lines, and under its fostering influences a great variety of institutions were developed and have increased in strength and importance with the growth of public sentiment regarding the value of scientific and technical education and the better definition of the proper limits and scope of education along these lines.

When it became apparent that the progress of these institutions would be seriously impeded without further provision by the National Government for their maintenance, Mr. Morrill secured the passage of the act of 1890, by which more than a million dollars is annually paid from the National Treasury to meet the expenses attending instruction in certain branches in these institutions.

We have in this country to-day 66 institutions organized under the Morrill acts of 1862 and 1890. These institutions have over \$50,000,000 in permanent endowments, buildings, and equipment, and an annual revenue of nearly \$6,000,000. They employ over 2,000 persons in their faculties and give instruction to about 30,000 students.

But Mr. Morrill was closely identified with other great institutions for the advancement of science and learning. He took an active part in building up the great Congressional Library and providing for the magnificent building with the aid of which this library is destined to be ever hereafter an important factor in the education of our people. He served for fifteen years as a regent of the Smithsonian Institution, during which time he labored persistently for the enlargement of the opportunities of the institution, and, among other things, he introduced and secured the passage of the act establishing the National Zoological Park. At the meeting of the board of regents of the Smithsonian Institution at which the death of Senator Morrill was announced one of the members of that distinguished body, in an address to his associates, used these words:

"In the grandeur of his country he felt the patriot's pride. He sought to make this Capital City worthy of the people to whom it belonged, and the Smithsonian Institution was regarded by him as a chief factor in its future greatness and renown.

"He was, in my judgment, a true American nobleman. Here, as elsewhere, distinction imposes obligations—*noblesse oblige*. No books of heraldry and no blazoned emblems are necessary to evidence the rank of Senator Morrill. His patent of nobility is recorded in the hearts of a grateful people."

CONVENTION OF ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS, 1898.

W. H. BEAL,

Office of Experiment Stations.

The fifteenth annual convention of the Association of Official Agricultural Chemists was held in the lecture hall of the Columbian University at Washington, D. C., November 11, 12, and 14, 1898. About 70 chemists were in attendance.

The annual address of the president, A. L. Winton, briefly reviewed the history and scope of the work of the Association, and pointed out some important new lines of investigation, among the latter being a study of materials used as insecticides and fungicides, and the establishment of standards of purity for foods, and especially for spices. Attention was called to the importance of using a greater variety of materials in the cooperative test of methods by the Association, so that these shall be strictly tests of the accuracy of the methods applied to all classes of substances as distinguished from trials of the skill of the analyst.

A committee, consisting of R. C. Kedzie and M. E. Jaffa, was appointed to wait upon the Secretary of Agriculture and invite him to attend the meetings of the Association. The Secretary appeared before the Association and addressed it briefly. He noted some of the more important ways in which the work of the chemist has benefited agriculture, dwelling especially upon the chemist's relation to sugar production, and suggested other lines of inquiry which might be profitably undertaken with a view to reducing our imports.

FERTILIZERS.

Nitrogen.—A report on this subject, prepared by R. J. Davidson, referee, was read by the secretary. This gave results of tests by 11 analysts of the modified Kjeldahl, modified Gunning, absolute, Ulsch-Kjeldahl, and Ulsch-Gunning methods on 12 samples of fertilizers containing nitrogen in various forms; as well as comparative tests by 12 analysts of the pepsin-hydrochloric acid and 2 per cent permanganate of potash methods for the determination of availability of organic nitrogen in fertilizers, on dried blood, cotton-seed meal, tankage, fish scrap, meat scrap, castor pomace, steamed leather, bone meal, and hoof meal.

The results indicated that the present official methods for nitrogen are satisfactory, and no changes in them were recommended by the referee.

C. H. Jones called attention to a study which had been made at the Vermont Station of the alkaline-permanganate method for determining the availability of organic nitrogen in fertilizers. The main results of this work are summarized as follows:¹

"(1) The alkaline-permanganate method (16 gm. potassium permanganate, 150 gm. sodium hydrate to 1,000 cc.; 100 cc. used in 600 cc. flask; digestion for an hour below boiling, followed by an hour's distillation), has shown in our hands broad distinctions between materials of animal origin of high and low nitrogen availability, provided amounts of substance equivalent to 0.045 gm. of nitrogen are used.

"(2) It is simpler and far more rapid than the pepsin-digestion method, and should prove particularly useful in eliminating quickly from a long list of fertilizers a large share of goods which would surely show high availabilities by the longer and more tedious processes. Its failure to show a sufficient availability with unacidified vegetable ammoniates may be overcome by the use of the pepsin method in doubtful cases.

"(3) Materials falling below 50 per cent nitrogen availability by this method are open to suspicion; those falling below 40 per cent are surely of little value for the production of crops. All such, however, should be likewise tested with pepsin, and, if opportunity admits, may be subjected to vegetation tests.

"(4) The alkaline-permanganate method should be considered an aid to vegetation tests rather than a substitute for them."

H. J. Wheeler, in discussing this subject, questioned the accuracy of the results of vegetation tests for availability of nitrogen in dried blood.

The referee for the ensuing year was instructed to further test the permanganate method.

Potash.—The report on potash was submitted by C. H. Jones. This report recorded the results obtained by 9 analysts in a comparison of the present Lindo-Gladding and optional methods for the determination of water-soluble and acid-soluble potash in wood ashes and cotton-hull ashes, as well as the results of tests of methods for determining chlorin in fertilizers.

The results indicated that these methods are accurate and reliable for the determination of potash in ashes. It is necessary, however, in the Lindo-Gladding method to see that the potassium-platinum precipitate is perfectly soluble in water.

B. B. Ross called attention to the fact that certain kinds of asbestos are attacked and dissolved to an appreciable extent by the ammonium chlorid solution used in washing the potassium-platinum precipitate.

The referee recommended the following method for determining chlorin in fertilizers, which has been used at the Vermont Station with satisfactory results for several years. To 50 cc. of the Lindo-Gladding solution for potash (equivalent to 1 gm. of original substance), add an excess of nitric acid and as many cubic centimeters of silver nitrate solution (1 cc. of which corresponds to chlorin equivalent to 1 per cent of potash, K_2O , on a basis of 1 gm. of substance) as the percentage of K_2O found +0.5 per cent; boil the solution for about 5 minutes, stir,

¹ Vermont Sta. Rpt. 1898, p. 171.

and allow the silver chlorid to settle. Decant a small portion of the supernatant liquid into a test tube. Test one portion of this for chlorin with a small crystal of silver nitrate and the other for silver with hydrochloric acid or ammonium chlorid. If an excess of silver is shown, collect the silver chlorid precipitate on a filter, dry, and weigh in the usual manner.

Phosphoric acid.—The referee on phosphoric acid, B. W. Kilgore, reported comparative tests by 19 analysts of the gravimetric and volumetric methods on cotton-seed meal, South Carolina rock, monosodium phosphate, and slag. A very close agreement between the results by the two methods was obtained.

High results were sometimes obtained in the volumetric method when a large excess of molybdic solution was used. Complete precipitation was obtained in the cold when the solution was shaken for 15 minutes or more.

H. A. Huston suggested that the occasional high results obtained by the volumetric method on slag might be due to the presence of manganese. This could be corrected by adding a small quantity of ferrous ammonium sulphate.

The volumetric method in the following slightly modified form was made provisional. Dissolve the substance according to prescribed methods, except that sulphuric acid must not be used. Make up to a convenient volume and use aliquots corresponding to 0.4 gm. of substance for percentages below 5 or 6, 0.2 gm. for percentages between about 6 and 20, and 0.1 for percentages above 20. Add 15 gm. ammonium nitrate, dilute to 75 to 100 cc., and heat in a water bath to 60 to 65° C. Add 20 to 25 cc. of freshly filtered molybdic solution for percentages below about 6, 30 to 35 cc. for percentages below about 20, and 40 cc. for percentages above about 20. Digest for 15 minutes, filter at once, and wash twice by decanting with water, using 25 to 30 cc. each time, agitating the precipitate thoroughly and allowing it to settle well. Transfer to filter and wash 5 or 6 times, using enough water to make with decantation washings about 200 cc. Transfer the precipitate to the precipitating vessel, dissolve in an excess of standard alkali, add a few drops of phenolphthalein, and titrate with standard (nitric) acid. Instead of precipitating in a bath at 60 to 65° C., the precipitation may be made at room temperature by shaking for about 30 minutes in some convenient form of shaking apparatus.

The referee suggested that convenient forms of filters for this work may be made by putting into the glass tube used for holding Gooch crucibles a perforated porcelain disk to which is attached a stout piece of wire. This wire extends through the neck of the tube, and is used to push out the filter and precipitate after filtration. The porcelain Gooch crucible with false bottom and the deep form of Hirsch funnel are also recommended. These three with felts of asbestos and suction give good filtrations.

Uniform fertilizer legislation.—The committee appointed by the Association to confer with a similar committee appointed by the Association

of American Agricultural Colleges and Experiment Stations on uniformity in fertilizer laws recommended the adoption of the following as points which should be made uniform in the laws of the several States:

“(1) All substances containing nitrogen, potash, or phosphoric acid, sold, offered, or exposed for sale for manurial purposes, excepting the dung of domestic animals when sold as such, should be subjected to inspection.

“(2) Each package of manurial substance as above defined, sold, offered, or exposed for sale, should bear a printed, legible guaranty.

“(3) The number of net pounds in each package should be stated.

“(4) Each package should bear the brand, name, or trade-mark and the name and address of the manufacturer.

“(5) The quantities of manurial ingredients should be expressed in percentages.

“(6) The guaranteed statements on the packages or forwarded to the inspectors need not be in the form of an affidavit.

“(7) Sealed samples of fertilizers offered for sale need not be sent by the manufacturers to the inspectors.

“(8) In lots of 5 tons or less, samples should be drawn from at least 10 packages, or if less than 10 packages are present, all should be sampled; in lots of over 5 tons, not less than 20 packages should be sampled.

“(9) Duplicate samples should be drawn and sealed in the presence of the party or parties in interest, or their representatives, one of the samples to be taken by the collector and the other left with the party whose goods were inspected, subject to the call of the manufacturer.

“(10) Total nitrogen should be guaranteed in all cases, and nitrogen in the form of nitrates or of ammonium salts should be guaranteed separately, if the manufacturer desires credit therefor.

“(11) Total phosphoric acid should be guaranteed in all cases, and soluble, reverted and insoluble separately, if the manufacturer desires credit therefor.

“(12) Potassium should be guaranteed as potash (potassium oxid) soluble in water.

“(13) When chlorin is present in fertilizers, manufacturers shall guarantee the maximum percentage thereof.

“(14) Only statements of the minimum amount of the substances present, except in the case of chlorin, should be made. For example, instead of guaranteeing from 2 to 4 per cent of potash, guaranties should read thus: 2 per cent of potash.

“(15) It should be specified that the methods of the Association of Official Agricultural Chemists should be used for official work.

“(16) An imprisonment clause for violation of fertilizer laws should be omitted.

“(17) Manufacturers should not be obliged to secure bondsmen.

“(18) Commercial valuations should not be affixed to the published analyses of manurial substances.

“(19) A definition of the term ‘brand’ should be inserted wherever a brand tax is assessed.

“(20) The guaranty should state the ingredients guaranteed in the following form and order:

“..... per cent phosphoric acid soluble in water.

“..... per cent phosphoric acid reverted.

“..... per cent phosphoric acid insoluble.

“..... per cent phosphoric acid total.

“..... per cent nitrogen in nitrates.

“..... per cent nitrogen as ammonia.

“..... per cent nitrogen total.

“..... per cent potash soluble in water.

“..... per cent chlorin.

“Ingredients not present should be omitted from the guaranty, and no other form of statement should be interpolated.”

The recommendations of the committee were adopted, and the committee was continued¹ with instructions to use every effort to carry into effect the recommendations of the report.

SOILS AND ASH.

Separate reports were submitted on these subjects, the first on soils by the referee, H. Snyder, the second on ash by the associate referee, B. L. Hartwell. The first summarized results of comparative tests by 8 analysts on soils of known deficiencies of the $\frac{1}{2}$ normal hydrochloric acid method for determining available phosphoric acid and the calcium chlorid and ammonium chlorid methods for determining available potash. In addition to these principal lines of work, determinations were made of total and humus nitrogen and calcium carbonate in the soils. In some of the determinations of potash the electrolytic method was used.

H. Snyder also presented a paper on "Problems in soil investigations," in which a plea was made for systematic soil study and uniform methods. The importance of taking into consideration the acid and basic characteristics of soils was pointed out, and the question of standards of fertility was discussed.

H. J. Wheeler read a paper on methods of determining the fertilizer requirements of soils, in which attention was called to the unreliability of soil tests of fertilizers under certain conditions, e. g., with a deficiency of lime or water. The conclusions of this paper were based upon the results of several years' experiments at the Rhode Island Station.

Two papers by C. G. Hopkins were submitted to the Association: (1) "A rapid method of mechanical soil analysis, including the use of centrifugal force," and (2) "A plea for a scientific basis for the divisions of soil particles in mechanical analysis."

H. W. Wiley spoke of the increasing importance of soil analysis, and referred to the Hawaiian soils as opening up new and interesting problems in soil investigation. He also called attention to the tendency to increased acidity in arable soils as a fact which should always be borne in mind in soil investigations.

H. Snyder, J. A. Myers, M. E. Jaffa, H. A. Huston, and H. J. Wheeler also discussed different phases of the question of soil investigation.

The $\frac{1}{2}$ normal hydrochloric acid method for available phosphoric acid gave very satisfactory results in the tests and was made a provisional method of the Association. In the method for determining humus nitrogen the soil is to be exhausted with 3 per cent sodium hydrate after treatment with 2 per cent hydrochloric acid and washing. The calcium chlorid method for determining available potash is abandoned.

¹The committee for the Association of Official Agricultural Chemists is H. W. Wiley, B. W. Kilgore, H. A. Huston, H. B. McDonnell, and B. B. Ross. The committee for the Association of American Agricultural Colleges and Experiment Stations is H. J. Wheeler, H. P. Armsby, E. H. Jenkins, M. A. Scovell, and C. D. Woods.

The referee for the next year was instructed to test the so-called international method (treatment with 3 per cent nitric acid) for determining available potash, and Hallemann's method (treatment with carbonated water) for determining lime, and also to further test the ammonium chlorid method for available potash.

B. L. Hartwell, associate referee, reported the results of comparative tests of methods by 3 analysts on hay ash. The results show that the accuracy of the methods is largely dependent upon the soluble silica present. The thorough revision of the methods was proposed, and it was suggested that they be tested on mixtures of known composition approximating the composition of ash.

FOODS AND FEEDING STUFFS.

The report on this subject, which was submitted by W. H. Krug, referee, gave the results of comparative tests by 13 analysts of the diastase method for carbohydrates in barley and bran, by 7 analysts of the phenylhydrazin and phloroglucin methods for pentosans in the same substances, and by 6 analysts of methods of determining galaetan. The importance of making a microscopic examination for the purpose of showing when the conversion of starch by the diastase is complete was brought out in these tests. The phloroglucin method for pentosans as a rule gave higher results than the phenylhydrazin method.

H. W. Wiley spoke of the difficulty of the exact determination of starch, but stated that in his opinion the diastase method is the best yet offered. He also stated it as his belief that our present methods account for all substances which occur in the nitrogen-free extract of cereals and cereal products. H. Snyder spoke of the importance of determining the acids in food. H. A. Huston suggested that a study of the alkali extract of foods and feeding stuffs would throw some light on the constitution of the nitrogen-free extract.

The following recommendations of the referee were adopted by the association: Three grams of material are to be used in the determination of starch by the diastase method. The substance is to be treated with diastase until the presence of starch is no longer shown by the microscope. The acid solution after inversion is to be nearly instead of exactly neutralized. The phloroglucin precipitate is dried by aspirating $\frac{1}{2}$ hour and then heating in an oven for $3\frac{1}{2}$ to 4 hours. In the diastase method blank determinations to test reagents should be made. In the determination of galaetan the material for the test, 3 gm., is to be extracted 5 times with 10 cc. portions of ether. The association voted to adopt the factors for calculating pentosans recently proposed by Krüger and Tollens¹ instead of those used at present in the official method. The referee called attention to the importance of using phloroglucin free from diresorcin. To detect this substance dissolve the phloroglucin in acetic acid and add a few drops of strong sulphuric acid. A violet color shows the presence of diresorcin.

¹ Ztschr. Angew. Chem., 1896, p. 33.

Food adulteration.—A report on this subject, by W. S. Sweetser, was read by the secretary. This report was confined to a discussion of results obtained by 3 analysts in determining starch in spices by the diastase and direct inversion methods. In this connection W. D. Bigelow spoke of the value of starch determination in detecting adulteration in spices. Standards and quick methods for this purpose are needed.

A. L. Winton referred to the work in this line at the Connecticut State Station, and stated that while microscopic examination is as a rule the most reliable means of detecting the principal adulterations in spices and similar products, chemical methods are urgently needed.

The referee suggested that his successor should compare different methods on spices low in starch, and also test the effect of longer digestion and interrupted digestion with diastase.

Food standards.—An elaborate report on this subject was presented by W. Frear, chairman of the committee appointed at the last convention to consider this subject. This report pointed out the inapplicability of European standards to American food products, and outlined an elaborate plan for the compilation of analyses of such material. In the plan proposed, the data are to be classified as follows: (1) Maxima, minima, and averages of the principal constituents of normal foods; (2) data showing the variations in composition due to differences in origin or treatment; and (3) the maxima of injurious constituents which normally occur in foods. In the organization of the work three subcommittees have been provided for: (1) On rules, forms, selection of data, etc., W. Frear, M. A. Scovell, and H. W. Wiley; (2) lists of food chemists of the world, H. A. Weber, E. H. Jenkins, and H. W. Wiley; and (3) digest of food laws, E. H. Jenkins, M. A. Scovell, and H. W. Wiley. A classification of the different food materials of which the analyses are to be compiled is given, and the different subjects are assigned to editors.

The following delegates to the pure-food congress were appointed: Delegates, H. W. Wiley, W. Frear, A. L. Winton, C. D. Woods, and W. D. Bigelow; alternates, W. O. Atwater, A. B. Peebles, H. J. Patterson, L. L. Van Slyke, and W. H. Krug.

DAIRY PRODUCTS.

C. L. Penny, referee, reported the results of tests by 4 analysts of the Leffmann-Beam and Reichert-Wolny methods for volatile fatty acids, and the provisional methods of the Association for albumin and casein. Incidentally the use of a reflux condenser *v.* a closed flask in saponification was also tested.

As a result of this work and on the recommendation of the referee, the Leffmann-Beam and present provisional methods were made optional, and it was prescribed that the fat should be weighed into the saponification flask from a weighing tube marked to contain 5.75 cc.

SUGAR.

The report of the referee on sugar, R. L. Hiltner, reviewed briefly the work of the Association on the subject, and gave the results of tests of methods by 7 analysts on a sample of beet molasses.

The Carr and Sanborn and the quartz-sand methods for water determination were made provisional. Creydt's method for raffinose and sucrose was also made provisional.

The secretary was directed to thoroughly revise all the methods for sugar, omitting (*b*) and (*c*) of the present official methods, and under (*e*) giving directions for the preparation of the permanganate solution used,¹ and incorporating in the methods the statement that the determination of water by means of density is not applicable to low-grade products.

H. W. Wiley called attention to the fact that efforts to secure international agreement as to methods of sugar analysis are meeting with considerable success. He therefore thought it unwise to make any radical changes in methods of sugar analysis at the present time.

TANNIN.

The referee on this subject, J. H. Yocum, reported the results of comparative tests of methods by 20 analysts on chestnut-wood extract, hemlock liquor, and an artificial tannin extract. Incidentally tests were made of 2 samples of hide powder. Numerous recommendations of the referee relating to quantity of material, directions for drying, filtration, preparation of hide powder, etc., were adopted by the Association.

MISCELLANEOUS.

The report of the abstract committee was presented by E. W. Allen, chairman. This report showed that the abstracts of literature relating to analytical methods covered 60 pages of the current volumes of the *Experiment Station Record*, beginning with Vol. 9, No. 4, and covering Vol. 10, No. 3.

A paper entitled "Report on an investigation of methods for the determination of nicotin in tobacco powders and extracts," by E. A. de Schweinitz, J. A. Emery, and F. K. Cameron, was presented to the Association. This paper reported the results of tests of different methods of determining nicotin, including Kissling's, Lloyd's, and the optical methods, with the results of special investigations by A. L. Winton and E. A. de Schweinitz and associates. Six analysts in different parts of the country took part in the comparison of methods. The results show the unreliability of the methods that are at present available for the determination of nicotin. This matter was deemed of such great importance, that the Association voted to appoint referees on the subject of insecticides and fungicides, who should be charged

¹ U. S. Dept. Agr., Division of Chemistry Bul. 46, p. 56.

with the duty of investigating such questions as those discussed in the paper.

A brief verbal report from the committee on volumetric standards was submitted by B. W. Kilgore. He recommended that no action be taken by this committee until the results of the deliberations of the International Congress at Vienna are known, but suggested that chemists in different parts of the country should make observations on the average temperature of their laboratories, with a view to deciding upon a normal temperature for the graduation of chemical apparatus. From the observations that the reporter had been able to make in two laboratories, he was inclined to believe that the normal laboratory temperature for a large part of the country was from 20 to 22°, rather than 15° C., as commonly assumed. The report of this committee was accepted and the committee was continued.

M. E. Jaffa invited the Association to hold its next meeting in California. The invitation was referred to the executive committee for consideration.

The thanks of the Association were voted the Columbian University, Cosmos Club, the Secretary of Agriculture, and the president and secretary of the Association.

OFFICERS OF THE ASSOCIATION.

Officers were elected for the ensuing year as follows: President, R. C. Kedzie; vice president, B. W. Kilgore; secretary, H. W. Wiley; executive committee—president, vice-president, secretary, and H. J. Wheeler and M. E. Jaffa.

The referees and associate referees are as follows:

Phosphoric acid: Referee, E. G. Runyan, Washington, D. C.; associate referee, H. K. Miller, Raleigh, N. C.

Nitrogen: Referee, B. L. Hartwell, Kingston, R. I.; associate referee, Thorn Smith, Moscow, Idaho.

Potash: Referee, B. B. Ross, Auburn, Ala.; associate referee, L. S. Munson, Agricultural College, Mich.

Soils and ash: Referee, M. E. Jaffa, Berkeley, Cal.; associate referee, W. R. Perkins, Agricultural College, Miss.

Foods and feeding stuffs: Referee, G. L. Teller, Fayetteville, Ark.; associate referee, F. W. Woll, Madison, Wis.

Dairy products: Referee, J. B. Weems, Ames, Iowa; associate referee, J. A. LeClere, Geneva, N. Y.

Liquors and food adulteration: Referee, H. A. Weber, Columbus, Ohio; associate referee, W. D. Bigelow, Washington, D. C.

Sugar: Referee, Elton Fulmer, Pullman, Wash.; associate referee, G. L. Spencer, Washington, D. C.

Tannin: Referee, O. Carr, Corry, Pa.

The abstract committee is as follows: E. W. Allen, Washington, D. C.; J. T. Anderson, Auburn, Ala.; W. H. Beal, Washington, D. C.; E. B. Holland, Amherst, Mass.; C. G. Jenter, Geneva, N. Y.; L. H. Merrill, Orono, Me.; H. Snyder, St. Anthony Park, St. Paul, Minn.; J. P. Street, New Brunswick, N. J.; and C. B. Williams, Raleigh, N. C.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

A volumetric citrate method for quick and exact determination of phosphoric acid in superphosphates, S. LITTMAN (*Chem. Ztg.*, 22 (1898), No. 68, pp. 691, 692).—The method proposed is as follows: Dissolve 10 gm. of superphosphate in $\frac{1}{2}$ liter of water, shake $\frac{1}{2}$ hour, and filter. To 50 cc. of the filtered solution add methyl orange and run in $\frac{1}{10}$ normal soda solution until a distinct yellow color appears, showing that the free phosphoric acid, H_3PO_4 , has been converted into monosodium phosphate, which reacts alkaline with methyl orange and acid with phenolphthalein. Add 10 cc. of neutral sodium citrate solution, prepared by exactly neutralizing a solution of 30 gm. of sodium hydrate in 120 cc. of water with pure concentrated citric acid, allow to stand 24 hours, filter, and dilute to 250 cc. This converts the unaltered monocalcium phosphate into monosodium phosphate. Phenolphthalein is then added, and soda solution run in until a red coloration appears, showing that the monosodium phosphate has been converted into trisodium phosphate. The number of cubic centimeters of soda solution required for this purpose multiplied by 0.71 gives the percentage of phosphoric acid.

This method and the gravimetric method were compared with very satisfactory results in a series of determinations of phosphoric acid in superphosphates made from Florida and Algerian phosphates, bone meal, and bone ash, and in spodium and mixed fertilizers. The average difference in 50 determinations by the two methods was 0.13 per cent.

On a new method of determining nitric acid, W. ACKERMANN (*Chem. Ztg.*, 22 (1898), No. 68, pp. 690, 691).—The method proposed is based upon the observation made by Kuhlmann¹ that ferrous hydrate heated with a nitrate solution is transformed into black oxid with evolution of ammonia. The details of the method are as follows: Place about 1 gm. of the nitrate in a half-liter flask with 30 cc. soda solution of 1.33 sp. gr. and 40 gm. of iron sulphate dissolved in water. The volume of solution should be about 160 cc. The iron sulphate solution is prepared by dissolving 308 gm. of the sulphate in 1 liter of water.

¹Gmelin-Kraut, 3, p. 301.

After thoroughly mixing the contents of the flask, add a small thimbleful of pulverized or reduced iron to prevent bumping, connect the flask with the condenser, and distil the ammonia into standard acid, heating cautiously at first to prevent frothing.

Method of determining nitrites in waters, L. ROBIN (*Jour. Pharm. et Chim.*, 6. ser., 7 (1898), No. 12, pp. 575-577; *abs. in Bul. Assoc. Chim. Suer. et Distill.*, 16 (1898), No. 1, pp. 83, 84).—This method is based upon the principle that when potassium iodid and acetic acid are added to a solution containing nitrites an amount of iodine is set free which is proportional to the amount of nitrites present.

To 50 cc. of the water to be examined add 2 cc. of a 20 per cent solution of pure potassium iodid and 2 cc. glacial acetic acid, stir and allow to stand exactly one-half hour, add a small amount of starch, and titrate with a solution of sodium hyposulphite prepared by diluting 50 cc. of decinormal solution to 1 liter.

A table is given which shows the amount in milligrams per liter of nitrous acid corresponding to the number of cubic centimeters of sodium hyposulphite used when 50 cc. of the water is taken for the test.

Concerning casein and its cleavage products in peptic digestion, F. ALEXANDER (*Ztschr. Physiol. Chem.*, 25 (1898), No. 5-6, pp. 411-429).—A study of the properties of casein prepared by the Hammarsten method, and of the products resulting in the fractional digestion with pepsin-hydrochloric acid.

The estimation of potash in soils, C. L. PENNY (*Delaware Sta. Rpt.* 1897, pp. 146-163, figs. 3).—See also Bulletin 36 of the station (E. S. R., 10, p. 134).

A new volumetric method for the determination of copper, R. K. MEADE (*Jour. Amer. Chem. Soc.*, 20 (1898), No. 8, pp. 610-613).—The copper is precipitated as cuprous thiocyanate, changed to oxid by heating with caustic alkali, treated with an excess of ferric chlorid or sulphate with a little dilute sulphuric acid, filtered, and the filtrate titrated with permanganate. The copper reduces a corresponding amount of the iron from the ferric to the ferrous form, and the iron equivalent to the permanganate multiplied by 1.125 gives the amount of copper in the sample.

The methods for examination of milk and its products, H. TIEMANN (*Die Untersuchungsmethoden der Milch und deren Producte*. Leipzig: M. Heinsius Nachf., 1898, pp. 61).—This is intended for food chemists, and deals especially with the methods employed in the control of butter and milk.

The determination of water in butter, margarin, etc., by means of acid-butyrometry, N. GERBER and M. M. CRAANDIJK (*Milch Ztg.*, 27 (1898), No. 38, pp. 593-595).—The results of 15 trials of the method, which is described, in comparison with the gravimetric results, are considered sufficiently exact for creamery and police control purposes.

The relations between the specific gravity and the insoluble fatty acids of butter and other fats, N. LEONARD (*Analyst*, 23 (1898), Nov., pp. 282, 283).—Four years ago the author found, on examination of 33 samples of butter, that the results might be represented by the formula $y = k(1 - x)$, in which y is the percentage of insoluble fatty acids, x the specific gravity at 100° F., and k a constant the mean value of which was found to be 951 ± 1.6 . Recently 30 additional samples were examined, and k was found to have the mean value 951 ± 1.8 . "This close agreement with the previous result is interesting as showing the constancy of the general character of the adulterants employed." The results obtained by calculation on the above basis and by determination of the insoluble fatty acids are given.

The determination of the Reichert-Meissl number, M. SIEGFELD (*Chem. Ztg.*, 22 (1898), No. 72, pp. 738, 739, fig. 1).—In determining the volatile fatty acids by the Reichert-Meissl method, it is proposed to measure the 5 gm. of fat with a pipette, instead of weighing it out. In a large number of trials the amount measured in this way ranged from 4.967 to 5.045 gm., and this variation would result in an error of from 0.2 to 0.3, which the author believes to be of little account in this determination. A water bath is described for use in heating and filtering the fat at the desired temperature. This accommodates 10 samples of fat at a time.

On the determination of undigested fat and casein in infant feces, H. POOL (*Jour. Amer. Chem. Soc.*, 20 (1898), No. 10, pp. 765-769).—Using the method previously described by the author (*E. S. R.*, 9, p. 917), examinations were made of 31 samples, the results of which are tabulated.

Microscopic water analysis, C. MEZ (*Mikroskopische Wassercanalyse. Berlin: J. Springer, 1898; abs. in Bot. Centbl.*, 75 (1898), No. 1, pp. 10-11).—Treats of the microscopic examination of drinking and drainage waters.

A study of the nitrogen contained in wine, J. LABORDE (*Ann. Inst. Pasteur*, 12 (1898), No. 8, pp. 517-540.)

The composition of æolosomine, A. B. GRIFFITHS (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 13, pp. 448, 449).—This is a so-called respiratory proteid.

The proteid and nonalbuminoid nitrogen in straw and chaff, *Deut. Landw. Presse*, 25 (1898), No. 65, p. 713).—The total protein and nonalbuminoid nitrogen in 25 kinds of straw and chaff of cereals and legumes is given.

Miscellaneous chemical work, C. L. PENNY (*Delaware Sta. Rpt. 1897*, pp. 163-165).—Discusses very briefly tests of methods of preserving and analyzing milk samples, and reports analyses (with reference to sugar content) of 4 varieties of sorghum which had been subjected to selective propagation for several years.

Lubricants for glass stop-cocks, F. C. PHILLIPS (*Jour. Amer. Chem. Soc.*, 20 (1898), No. 9, pp. 678-681).—A mixture of pure rubber 70 parts, spermaceti 25 parts, and vaseline 5 parts "lubricates well, is translucent, adheres to the glass, and is not saponifiable. . . . Another preparation which gave still better results was made by mixing pure rubber 70 parts and yellow unbleached beeswax 30 parts. . . . A thick rubber and wax mixture is especially suited for well-ground glass stop-cocks upon gas vessels which are to be exhausted and which have therefore to sustain the full pressure of the atmosphere. Such mixtures have been in use for stop-cocks of ordinary burettes in volumetric work during about two years, and have given satisfactory results in every way."

BOTANY.

A revision of the North American species of *Calamagrostis*, T. H. KEARNEY (*U. S. Dept. Agr., Division of Agrostology Bul. 11*, pp. 7-42, fig. 1).—This is a monographic revision of the North American species of *Calamagrostis*, together with notes on geographic distribution, ecology, teratology, and hybridism. A list is given of excluded species and an analytical key to the species recognized. The new species described by the author are: *Calamagrostis lemmonii*, *C. foliosa*, *C. angusta*, *C. subflexuosa*, *C. fasciculata*, *C. nemoralis*, *C. alaskana*, *C. laxiflora*, *C. micrantha*, *C. californica*, and *C. labradorica*. In all 38 species and a number of varieties are enumerated.

Descriptions of new or little-known grasses, F. LAMSON-SCRIBNER (*U. S. Dept. Agr., Division of Agrostology Bul. 11*, pp. 42-60, pls. 17, figs. 11).—Descriptions are given with reference to habitat, etc., of a number of new or poorly known species of grasses.

Those described as new are: *Panicum linearifolium*, *P. equilaterale*, *P. implicatum*, *P. wrightianum*, *Chatochloa latifolia*, *Stipa williamsii*, *S. nelsoni*, *S. minor*, *Muhlenbergia palustris*, *Sporobolus palmeri*, *S. thurberi*, *S. simplex*, *Agrostis paludosa*, *Trisetum argenteum*, *Zeugites pringlei*, *Eragrostis viscosa*, *Poa capillaris*, *P. juncifolia*, *P. hanseni*, *P. atropurpurea*, *P. longipedunculata*, *Agropyron elmeri*, *A. brevifolium*, *Elymus capitatus*, *E. hanseni*, and *E. ciliatus*. *Elymus saricocolus* Scribner and Smith and *E. simplex* Scribner and Williams are also described. In addition to the above a few new combinations are given as a result of changes in nomenclature.

The principal poisonous plants in the United States, V. K. CHESNUT (*U. S. Dept. Agr., Division of Botany Bul. 20, pp. 60, figs. 31*).—The author has given concise and illustrated descriptions of many of our most common poisonous plants, the number considered embracing about 50 species. The arrangement of the plants is according to the scientific classification at present most generally accepted, but by the liberal use of common names and a brief outline of geographic distribution any of the species would be easily recognized. The following are the species enumerated: Fly amanita (*Amanita muscaria*), death cup (*A. phalloides*), American false hellebore (*Veratrum viride*), lily-of-the-valley (*Convallaria majalis*), showy lady's slipper (*Cypripedium reginae*), larger yellow lady's slipper (*C. hirsutum*), smaller yellow lady's slipper (*C. parviflorum*), corn cockle (*Agrostemma githago*), aconite (*Aconitum columbianum*), larkspurs (*Delphinium tricorne*, *D. geyeri*, *D. menziesii*, *D. recurvatum*, and *D. trolliifolium*), black cherry (*Prunus serotina*), Kentucky coffee tree (*Gymnocladus dioica*), woolly loco weed (*Astragalus mollissimus*), stemless loco weed (*Aragallus lambertii*), rattlebox (*Crotalaria sagittalis*), caper spurge (*Euphorbia lathyris*), snow-on-the-mountain (*E. marginata*), poison ivy (*Rhus radicans*), poison oak (*R. diversiloba*), poison sumac (*R. vernix*), red buckeye (*Æsculus puvia*), water hemlock (*Cicuta maculata*), Oregon water hemlock (*C. vagans*), poison hemlock (*Conium maculatum*), broad-leaf laurel (*Kalmia latifolia*), narrow-leaf laurel (*K. angustifolia*), great laurel (*Rhododendron maximum*), stagger-bush (*Pieris mariana*), branch ivy (*Leucothöe catesbaei*), false jessamine (*Gelsemium sempervirens*), Jimson weeds (*Datura stramonium*, and *D. tatula*), black nightshade (*Solanum nigrum*), bitter-sweet (*S. dulcamara*), spreading nightshade (*S. triflorum*), and sneeze-weed (*Helenium autumnale*).

Hybrids and their utilization in plant breeding, W. T. SWINGLE and H. J. WEBBER (*U. S. Dept. Agr. Yearbook 1897, pp. 383-420, pls. 1, figs. 13*).—The authors have given a statement concerning hybrids and their utilization in plant breeding, most of the information being compiled. Hybrids are defined and the methods of producing them are fully explained. Notes are also given on plants which may be hybridized and the effect of the different crossings on the hybrid progeny.

A grouping of hybrids is given according to their resemblance to their respective parents. The descendants of hybrids, the difference between reciprocal hybrids, prepotency of pollen from one plant to another, increased vigor of hybrids and cross-bred plants, direct action of foreign pollen on the mother plant, and graft hybrids are discussed.

The practical utilization of hybrid plants in plant breeding is discussed at considerable length and some of the special features obtained by hybridizing pointed out.

Chlorophyll assimilation in littoral plants, E. GRIFFON (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 13, pp. 449-452).—The author has made a study of the plants which are characteristic of the flora along the seashore and are also found growing in saline soils in the interior. Specimens were collected under the same conditions both from the littoral flora and from the interior of France and examined microscopically, the following species being used: *Atriplex hastata*, *Beta maritima*, *Lycium barbarum*, *Plantago major*, *Tussilago farfara*, *Senecio vulgaris*, *Polygonum aviculare*, and *Medicago lupulina*. From his investigations it is stated that maritime plants, while undergoing a reduction in the amount of chlorophyll, due to the marine salts, have acquired a greater thickness and marked increase in the assimilating tissue; but this modification of structure is not able to entirely overcome the action produced by the salts. Assimilation in proportion to a unit of leaf surface is less in leaves of littoral plants than the same species growing in the interior.

Influence of light on the form and structure of plants, MAIGA (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 11, pp. 420-423).—The author has made a study of the influence of light on the branching of *Ampelopsis hederacea* and *Glechoma hederacea*. Both of these plants possess flowering and climbing or running branches that are quite dissimilar. In each case the flowering branches have very short internodes and the leaves are crowded toward the summit, while the climbing and running branches are characterized by a very rapid growth and elongated internodes. The plants were grown under a number of different conditions of illumination, and it was found that diffused light favors the formation of climbing or running branches and is able to transform the flowering buds into climbing or running ones. It also exerts a marked influence in changing the morphological and anatomical characters which are characteristic of climbing or running branches. Direct illumination produces the opposite effect.

Influence of mutilating seed on the development of the plants, E. GAIN (*Proc. Assoc. Franc. l'Avancement Sci.* 1897, pp. 463-468).—The author gives an account of experiments conducted with seed of lupines to test the effect of removing one or both cotyledons on the growth and development of the plants. The seeds were soaked for 40 hours and comparable lots were selected and planted in pots in which the soil was the same. After 12 days the young plants were divided into three

groups, one of which had both cotyledons removed, another had one removed, while the third lot developed in the normal way. The author describes the effect of this treatment on the growth and the morphological characters of the different plants. The mutilation of cotyledons was found to retard the growth, reduce the number of leaves as well as the number and size of the leaflets, and greatly modify the general habit of growth of the plants. In the case of those in which both cotyledons were removed the plant developed in the form of an inverted cone, while the normal plant has a tendency to a more cylindrical shape. The normal plant has usually 7, rarely 5 or 6, leaflets, while with those plants which had both cotyledons removed, 5, and sometimes 4, leaflets was the rule. The author states that this experiment will have an important bearing in showing the possible influence of the mutilation of seeds by weevil, etc.

The physiological function of iron in plants, J. STOKLASA (*Compt. Rend. Acad. Sci. Paris, 127 (1898), No. 5, pp. 282, 283*).—The author states that it having been shown by Gautier and Molisch that iron is not found in chlorophyll, and that his own experiments show it does not exist in the chlorolecithin, he has been led to investigate the possible relation of iron with the cell nucleus. From onion bulbs he has succeeded in isolating a substance that in chemical composition almost exactly agrees with the hematogen which Bunge has extracted from the yolk of eggs. The author has compared the various properties of the two substances and finds them practically identical. He states that chemical and microscopical observations show that a great part of the iron in plants is localized in the embryo or endosperm, and during germination it is employed by the plant in forming nuclei of the cells of the growing tissues. The effect of depriving young plants of iron can be readily shown with cultures of maize, in which the plant quickly perishes if from the nutritive solution iron be omitted. It is stated that it is impossible to extract hematogen from starved plants. Plants without chlorophyll are said to act in the same way, as shown in the case of *Mucor mucedo*, and hematogen has been isolated from the common *Boletus edulis*. The author concludes from his investigations that iron as well as phosphorus plays an important rôle in the formation of the cell nucleus.

A revision of the genera Chloris and Eustachys in North America, G. V. NASH (*Bul. Torrey Bot. Club, 25 (1898), No. 3, pp. 432-450*).—According to the author, as revised, the species of *Chloris* known to North America are 10 and those of *Eustachys* 4.

New species of Alabama fungi, C. H. PECK (*Bul. Torrey Bot. Club, 25 (1898), No. 7, pp. 368-372*).—As a contribution from the Alabama Biological Survey, the author describes 10 species of fleshy fungi.

American grasses, I, F. LAMSON-SCRIENER (*U. S. Dept. Agr., Division of Agrostology Bul. 7, pp. 331, figs. 302*).—A revised edition of this bulletin (*E. S. R., 9, p. 327*).

New plants from Wyoming, A. NELSON (*Bul. Torrey Bot. Club, 25 (1898), No. 7, pp. 373-381*).—This is the third contribution of the author descriptive of noteworthy species of plants in Wyoming, and contains descriptions and notes of 14 new species.

Some brief notes on the Swedish plant improvement investigations at Svalöf, N. H. NILSSON (*Malmö (Sweden), 1898, pp. 14. In German.*)

Native poison plants, A. MORRISON (*Producers' Gaz. and Settlers' Rec. [West. Australia], 5 (1898), No. 3, pp. 214-218, figs. 4.*)—Descriptive notes are given of the following plants, which are reputed as being poisonous to cattle: *Oxylobium retusum*, *Gastrolobium callistachys*, *G. parvifolium*, and *G. trilobum*.

The poison plants of Western Australia, A. MORRISON (*West Australian Settler's Guide and Farmer's Handbook, 1897, pt. 3, pp. 572-592.*)—Notes are given on various poisonous plants, the most of which belong to the two genera *Gastrolobium* and *Oxylobium*. All of these plants are poisonous to stock, and methods for their eradication are suggested.

Homology of the members of the plant body, with special reference to the question of homology involved in the alternation of generations in green plants, F. O. BOWER (*Gard. Chron., 3. ser., 24 (1898), No. 612, p. 221.*)—A brief résumé is given of the presidential address of the author before the Botanical Section of the British Association at its meeting September 8. 1898.

The number and symmetry of the fibrovascular bundles in the petiole as a character in determining species, A. CHATIN (*Compt. Rend. Acad. Sci. Paris, 127 (1898), No. 6, pp. 301-307.*)

Origin of lenticels, H. DEVAUX (*Compt. Rend. Acad. Sci. Paris, 126 (1898), No. 20, pp. 1432-1435.*)—The author gives a report on the origin of the structures forming lenticels.

The nature and origin of stipules, A. A. TYLER (*Ann. New York Acad. Sci., 10 (1898), No. 1-12, pp. 1-49, pls. 2.*)

The splitting of fruits and tubers (*Gard. Chron., 3. ser., 24 (1898), No. 611, p. 198.*)—Editorial notes are given on the physiological causes which result in the splitting of various fruits and tubers.

Concerning some caryophyllaceous hybrids, K. FRITSCH (*Oesterr. Bot. Ztg., 48 (1898), No. 10, pp. 381-385.*)—Hybrids between species of *Saponaria* and of species of *Gypsophila* are described.

The insect visitors of flowers, J. H. LOVELL (*Bul. Torrey Bot. Club, 25 (1898), No. 7, pp. 382-390.*)—The author has given descriptions of the methods for fertilization of various flowers and the insect visitors of *Gautheria procumbens*, *Chelone glabra*, *Impatiens biflora*, *Cornus canadensis*, *C. stolonifera*, *C. alternifolia*, and *Aralia racemosa*.

Sex in plants, J. HOOPES (*Pennsylvania Dept. Agr. Rpt. 1897, pp. 665-678, figs. 10.*)—A reprint of Pennsylvania Dept. Agr. Bulletin 30 (E. S. R., 9, p. 812).

A permanent stain for starch, J. H. SCHAFFNER (*Jour. Appl. Micros., 1 (1898), No. 10, p. 181.*)—By the use of anilin-safranin and gentian-violet a permanent stain may be secured.

On the preservation of materials in paraffin, C. JANET (*Bul. Soc. Zool. France, 23 (1898), No. 7-8, pp. 117, 118.*)

Plant physiological and agricultural-chemical researches during 1897, H. JENSEN (*Tidsskr. Landökou, 17 (1898), No. 3-4, pp. 314-331.*)

FERMENTATION—BACTERIOLOGY.

A preliminary arrangement of the species of the genus *Bacterium*, F. D. CHESTER (*Delaware Sta. Rpt. 1897, pp. 53-145.*)—The author proposes a scheme for the description of bacteria, which is thought to be sufficient in detail for the identification of the different species. A table is given in which the name, synonyms, habitat, and morphology of 354 species of *Bacterium* are given, together with their staining peculiarities, temperature conditions, description of their appearance in gelatin and agar cultures, gelatin stab. and slant cultures, agar cultures, potato cultures, bouillon cultures, milk cultures,

litmus-milk cultures, and pepton-rosolic acid solution, are described, together with their action in fermentation tubes, chemical relations, and pathogenesis.

In an appendix 10 species of bacteria associated with diseases of plants are briefly noted, which the author claims are not sufficiently described or are of such a habit as to make their classification by the foregoing scheme impossible.

The work concludes with an index of the more important literature of species of the genus *Bacterium*.

Bacteriological examination of drinking water, F. D. CHESTER (*Delaware Sta. Rpt. 1897*, pp. 42-53).—During the past year a considerable portion of the bacteriologist's time has been taken up with the examination of different samples of drinking water. The different methods of examination are reviewed and the method of Smith¹ is given in some detail. This method consists practically of the following manipulations: To each of a series of 10 fermentation tubes containing 1 per cent glucose bouillon, are added quantities of water varying from 0.1 to 1 cc., and are kept at 37 to 38° C. If after 3 or 4 days one or more of the tubes are found to contain from 40 to 60 per cent of gas, and if the reaction of the liquid is strongly acid, the presence of the colon bacillus is regarded as certain. In the author's experience this method is not wholly accurate, and details are given of several cultures showing that the appearance of the colon bacillus can only be certainly established by isolating the organism and by its cultural characteristics. The claim that the above-described method of treatment gives absolute results the author thinks should be qualified to mean the possible evidence of the presence of this particular germ.

A simple steam sterilizer, F. G. NOVY (*Jour. Appl. Micros.*, 1 (1898), No. 2, p. 33, fig. 1).

An atlas of bacteriology, C. SLATER and E. J. SPITTA (*London: Scientific Press, 1898*).

Laboratory methods in bacteriology: Detection of pathogenic organisms, F. G. NOVY (*Jour. Appl. Micros.*, 1 (1898), No. 10, pp. 175-178, figs. 2).

Laboratory directions for beginners in bacteriology, V. A. MOORE (*Ithaca, 1898*, pp. VI+89).

A practical guide to the bacteriological analysis of pus, blood, saliva, milk, urine, water, soil, etc., L. FELTZ (*Guide pratique pour les analyses de bacteriologie clinique, pus, sang, crachat, lait, urine, eau, sol, etc. Paris: J. B. Baillière, 1898*, pp. 282, figs. 111).

Technical mycology: The utilization of micro-organisms in the arts and manufactures, F. LAFAR. Transl. by C. I. C. SALTER (*Philadelphia: J. B. Lippincott Co., 1898*, Vol. I, pp. IX+405, pl. 1, figs. 90).—This valuable contribution is a practical handbook on fermentation and fermentative processes for the use of brewers, distillers, analysts, technical and agricultural chemists, pharmacists, and all interested in the industries dependent on fermentation. The first volume, the only one at hand, treats solely of schyzomycetic fermentation. The immense strides that mycology has made in the arts are seldom appreciated until such a work as the present volume is carefully examined.

¹Centbl. Bakt. u. Par., 1, Abt., 18 (1895), p. 494.

A few of the many topics discussed are distilling, brewing, wine making, manufacture of vinegar, dairying, preparation of folders of various kinds, tobacco and sugar manufacturing, fixation of free atmospheric nitrogen, nitrification, etc. The subjects have been treated from the botanical, technical, and chemical standpoints, particular stress being paid to the latter two. Special sections are devoted to the decomposition and transformation of organic nitrogenous compounds and on oxidizing fermentation, in which a large fund of information is given relative to the bacterial processes involved in the breaking up of various organic compounds.

The historical development of the subject is treated in a very interesting and complete manner and the account of the various systems of classification of bacteria is most valuable. The principles of sterilization and pure cultivation are rather briefly but very clearly stated.

Mechanically the book is well made, and the only serious fault to be found with it is the lack of an index, a serious omission we believe in any work. This will doubtless be given in the concluding volume, but in such a work its usefulness is greatly increased by making every volume, complete in itself. The same objection can be offered the system of references. A very complete table of contents will aid somewhat in overcoming the difficulties experienced by the lack of an index. In all probability this work will for sometime to come be the most elaborate and useful treatise in English on the subject.

ZOOLOGY.

Birds that injure grain, F. E. L. BEAL (*U. S. Dept. Agr. Yearbook 1897*, pp. 345-354).—According to the author the more important grain-eating birds in the United States are the crow, crow blackbird, red-winged blackbird, yellow-headed blackbird, rusty grackle, and cowbird. The food habits, breeding places, etc., of the different birds are noted as well as the causes which account for the increase of some of the birds. It is stated that apparently few birds willingly subsist exclusively upon any one kind of grain for a considerable time, and on the other hand they have a marked fondness for the seeds of certain useless plants. The ravages which they occasionally cause are explained on the ground of too many birds of the same or closely allied species within a limited area. An attempt to exterminate the species is regarded as ill advised and hopeless. It would doubtless be possible to diminish the number of birds when desirable.

“With the breeding places more restricted and an environment otherwise changed by increased population, the number of birds must surely decrease, and in time the proper equilibrium will be restored. In the meantime it behooves the farmer to apply such remedies as the exigencies of the case suggest, and where these gregarious species are over abundant it might be well to exempt them from the general protective laws, in order that each landholder may be free to protect himself as best he can.”

Further notes on the birds of Colorado, W. W. COOKE (*Colorado Sta. Bul. 44*, pp. 147-176).—This is considered as an appendix to Bulletin 37 of the station (E. S. R., 9, p. 229), and contains notes on the results of investigations made since the former bulletin was published. The total number of birds now known to occur in Colorado is 374, of which 236 breed there.

The white or barn owl (*Bd. Agr. [London] Leaflet No. 51*, pp. 4, fig. 1).—The white or barn owl (*Strix aluco* or *S. flammea*) is described, and information concerning its food habits, etc., quoted from a number of sources. The fact is pointed out that this bird is useful and that it should be protected. The wild birds' protection act, which applies to the white or barn owl, is cited.

On the systematic destruction of woodchucks, F. H. STORER (*Bul. Bussey Inst., 2 (1898), No. 7*, pp. 422-428).—The author discusses attempts to destroy woodchucks with vapor from volatile liquids, such as bisulphid of carbon, and by poisons. Experiments in smoking woodchucks in their burrows are reported. Earlier attempts were made with sulphur or touch paper, but the best results were obtained with a torch made of sodium nitrate 12 parts, sulphur 6 parts, mealed gunpowder 4 parts,

antimony sulphid 2 parts. The author also quotes a method of destroying wood-chucks by exploding cartridges of common blasting powder or dynamite in the burrows.

The determination and regulation of sex, SCHILLER (*Milch Ztg.*, 27 (1897), No. 37, pp. 580-582).—The author summarizes some of the principal investigations on the determination of sex in animals and compares it with recent work with men along the same lines.

Microtechnique of animal morphology; a critical description of microscopical experimental methods, APATHY (*Die Mikrotechnik der tierischen Morphologie. Eine kritische Darstellung der mikroskopischen Untersuchungsmethoden.* Braunschweig: H. Bruhn, 1896, pt. 1, pp. 320, figs. 10; rev. in *Centbl. Bakt. u. Par.*, 1. Abt., 24 (1898), No. 2-3, pp. 100, 101).

On a green leucocytosis in oysters associated with the presence of copper in the leucocytes, R. BOYCE and W. A. HERDMAN (*Proc. Roy. Soc. [London]*, 62 (1897), No. 379, pp. 30-38).—The authors report a number of experiments. Copper was found in green oysters in much larger quantity than in white oysters.

METEOROLOGY.

Report of the meteorologist, W. H. BISHOP (*Delaware Sta. Rpt.*, 1897, pp. 211-229).—Monthly summaries of observations at 6 different places in Delaware on temperature, atmospheric pressure, and precipitation during the year ending June 30, 1897, and a summary of observations on temperature and precipitation during the calendar year 1896 are given and the data briefly discussed.

The summary for 1896 is as follows:

Annual summary of meteorological observations in Delaware.

Locality.	Temperature.			Total rainfall.	No. days on which 0.01 in. or more of rain fell.
	Highest.	Lowest.	Mean.		
	Deg. F.	Deg. F.	Deg. F.	Inches.	
Newark	98	0	52.24	31.13	96
Middletown	100	2	53.20	36.55	83
Dover	98	6	54.11	41.85	83
Milford	98.5	9	56.02	46.48	88
Seaford	97	6.5	54.98	47.98	93
Millsboro	98	6	54.44	44.74	111

Rainfall of the crop season, A. J. HENRY (*U. S. Dept. Agr. Year-book* 1897, pp. 607-618, charts 5).—Tables and charts show the monthly and seasonal averages of rainfall, April to September, of the different States and Territories; the averages and least rainfall of the region east of the one hundredth meridian; variations in rainfall; and date of appearance of first and last killing frost. The data are briefly discussed.

The mean annual rainfall of the globe, R. DEC. WARD (*Science*, n. ser., 8 (1898), No. 198, pp. 507, 508).—This article briefly discusses Loomis and Supan's rainfall maps, Symon's report on "British rainfall in 1897," Todd's report on "Rainfall in South Australia and the Northern Territory, and that portion of the bibliographical number (for 1897) of *Annales de Geographie* which contains notes on climatology and meteorology.

Meteorology in Denmark, 1896-97, V. WILLAUME-JANTZEN (*Tidsskr. Landökon.*, 17 (1898), No. 1-2, pp. 88-101).

AIR—WATER—SOILS.

Some interesting soil problems, M. WHITNEY (*U. S. Dept. Agr. Yearbook 1897, pp. 129-140*).—This is a discussion of the peculiar physical properties of certain soils of the extreme West which “absorb moisture so readily, lose it through evaporation so slowly, and yet supply the needs of plants so regularly and abundantly that they can stand long periods of drought, during which the crops continue to grow without any signs of suffering for lack of water.”

Certain soils in the San Joaquin Valley, California, in the region of Tulare and Fresno, seem to have a remarkable power of transporting water for the use of crops. Less than 10 in. of rain falls during the year and none falls during the growing season, and standing water is probably 12 to 25 ft. below the surface; yet good crops are grown without irrigation provided the irrigation canals are allowed to run, the seepage apparently supplying in some unexplained way the water needed. “At . . . Chino, San Bernardino, Claremont, and Pomona there are certain soils upon which crops are grown without irrigation. There are on an average between 17 and 18 in. annual rainfall at these places, the most of which falls during the winter months. Less than an inch of rain falls on the average during the 5 months of the growing season, from May to September, inclusive.” This is an artesian district, but the surface wells are from 20 to 40 ft. deep.

Similar conditions have been noted elsewhere in the region of deficient rainfall, notably “in the great wheat areas in the northern part of the San Joaquin Valley of California, in the Palouse district around Pullman, Washington, and on the foothills at Wallawalla, Washington, and at Bozeman, Montana, where there are soils which produce fine crops of wheat without irrigation,” although the rainfall amounts to from 13 to 18 in. and most of it falls during the winter months, and ground water is from 30 to 40 ft. below the surface.

Soils of the Mohave desert with 3 in. annual rainfall, of which only 0.3 in. falls in the season from May to September, were examined about the middle of September, “at least 20 miles from the mountains, in the midst of a level plain.”

“Contrary to expectation, the soil at a depth of from 12 to 18 in. below the surface was still quite moist, in spite of the fact that no rain had fallen for at least 5½ months. The surface wells vary in depth from 6 to 30 ft., occasionally being 200 ft. deep. On certain parts of the desert it is the common practice to dig holes 6 to 10 ft. deep and allow them to fill up with water for the use of the stock. The distance to water varies according to the nature of the soil, just as it does in the humid portions of the country. The soils in which the water is close to the surface are, as a rule, impregnated with alkali. There is an artesian belt under a portion of the desert.

“Investigation showed the same conditions to exist on the Nevada and Utah deserts between Reno and Ogden. The annual rainfall is between 5 and 6 in., the seasonal rainfall about 1 or 2 in. on the average. It is stated that water can be found on these deserts about 30 ft. below the surface, although the water may be so strongly impregnated with salts that it is unfit for use. . . .

"A fact which makes more remarkable this extraordinary power of the soils to absorb and retain a sufficient quantity of water for the needs of crops for 5 or 6 months after the rain ceases is the very low relative humidity of the atmosphere. Records of the relative humidity have been taken from only a few of the places under consideration, and these are given in the following table:

Mean annual and seasonal relative humidity.

Locality.	Annual.	May to September.	July and August.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Tulare, Cal.....	58	42	35
Walla Walla, Wash.....	62	47	39
Miles City, Mont.....	65	52	46
Bismarck, N. Dak.....	72	67	65
Humboldt, Nev.....	48	36	31

"The mean relative humidity of New England for July and August, 1897, determined from the reports of 7 Weather Bureau stations, was 85 per cent. At Walla Walla the mean relative humidity from May to September was only 47 per cent and for July and August 39 per cent. It is hardly conceivable that under these extremely dry conditions the foothills soil could maintain sufficient water from the winter rains to supply the loss due to evaporation from the surface of the soil and to transpiration by the plant for months after the rain had ceased to fall. At Tulare the mean relative humidity during the growing season is 42 per cent and 35 per cent during the months of July and August—conditions which practically prevail at Fresno. Nevertheless, at Fresno, with nearly the same rainfall, and where crops must transpire great quantities of moisture into the dry atmosphere, the soil maintains an adequate supply of moisture for the plants, provided the water continues to run in the canals, although these may be as much as a mile apart. . . .

"At Humboldt, on the Nevada desert, the relative humidity from May to September is about 36 per cent and in July and August 31 per cent. The conditions over the Mohave desert are probably not dissimilar from those at Humboldt and Tulare."

These peculiar soil conditions suggest the importance of study of "the great power these soils have of retaining moisture and of supplying it rapidly and regularly to the crops as it is needed. If such power can be imparted to other soils of a droughty character, especially to our soils in the East, it will be of immense value to the farmer.

"The first question to solve is the distribution of the rainfall. It is important to determine the depth to standing water; that is, the average depth of wells. Then it is very important to know whether any portion of the rainfall passes down into this stratum and runs off into the drainage." The use of the electrical method for this purpose is explained.

It is important to know whether the annual rainfall in these soils descends low enough to form any connection with the underground drainage water, and if it does not, whether the small amounts of rainfall occurring during the winter months in these regions are "sufficient to maintain crops for 5 or 6 months of dry weather," with "a low relative humidity and often high temperature of the atmosphere, without any additional water supply from any source."

Tables give the mean annual and seasonal rainfall at 48 places in the regions referred to and mechanical analyses of 14 samples of soils from the same region. The composition of these soils is as follows:

Mechanical analyses of soils.

Locality.	Description.	Moisture in air-dry sample.		Organic matter.		Gravel (2-1 mm.).		Coarse sand (1-0.5 mm.).		Medium sand (0.5-0.25 mm.).		Fine sand (0.25-0.1 mm.).		Very fine sand (0.1-0.05 mm.).		Silt (0.05-0.01 mm.).		Fine silt (0.01-0.005 mm.).		Clay (0.005-0.0001 mm.).

Lavas and soils of the Hawaiian Islands, W. MAXWELL ET AL. (*Honolulu: Hawaiian Gazette Company, 1898, pp. 186, pls. 1, map 1*).—This is an account of investigations¹ by the Hawaiian Experiment Station and Laboratories published by order of the Hawaiian Sugar Planters' Association. The subjects studied were (1) origin and nature of Hawaiian soils and (2) availability and loss of the elements of plant food in Hawaiian soils.

Origin and nature of Hawaiian soils.—"The soils of these islands are derived from volcanic lavas. Among Hawaiian lavas are those which have been discharged from craters, flowing and cooling into rocks having the composition of normal basalts. Others, originally of the same composition, have undergone such alteration that they now compose masses having a radically different chemical composition and color appearance. This alteration took place at the time of ejection, and under the action of chemical causes, and previous to the later action of secondary causes of rock disintegration, such as weathering, which has apparently been the only agent of decomposition of certain of the normal lavas."

The results are reported of detailed chemical studies of the undecomposed lavas and of those which have undergone more or less change by weathering or under the influence of steam and sulphurous vapors. The processes of decomposition of lava under the influence of steam and sulphurous vapors were studied in the craters of Kilauea and other volcanoes. The changes which the lavas have undergone in the process of transformation into soils are shown by the following comparison of

¹ For account of previous investigations on soils see E. S. R., 7, p. 937.

the composition of unaltered lavas with the average of about 600 soils derived from them (calculated to the basis of mineral matter):

Average composition of Hawaiian lavas and soils.

	Silica.	Ferrous and ferric oxids.	Aluminum oxid.	Calcium oxid.	Magnesium oxid.	Sodium oxid.	Potassium oxid.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Hawaiian lavas.....	47.90	13.36	18.23	8.99	6.05	2.20	1.50
Hawaiian soils.....	27.54	36.45	22.64	.46	1.07	1.19	.62

On the basis of the studies made the soils of the islands are classified geologically as follows:

“(1) *Dark red soils* formed by the simple weathering of normal lavas, in climatic conditions of great heat and dryness.

“(2) *Yellow and light red soils* derived from lavas that underwent great alteration under the action of steam and sulphurous vapors at the time of or after emission from the craters.

“(3) *Sedimentary soils* derived from the decomposition of lavas at higher altitudes and removal and deposition by rainfall at lower levels.

“In addition to the classification based on geological differences in the lavas the soils have been further considered in classes dictated by the results of climatic conditions as follows:

“(1) *Upland soils* formed under lower temperatures and greater rainfall, and distinguished by a large content of organic matter and nitrogen and by a low content of the elements of plant food in an available state, these elements having been removed by rainfall.

“(2) *Lowland soils* formed under higher temperature and smaller rainfall, and characterized by a lower content of organic matter and nitrogen and by a higher content of the elements of plant food in a state of immediate availability, which is due in part to the receipt of some soluble constituents from the upper lands and to a smaller rainfall over the lower levels.”

The composition of some of these soils is shown in the following table, which gives the average of over 1,300 analyses. The mineral constituents reported were determined by digesting the soils in hydrochloric acid of 1.115 specific gravity for 10 hours in a boiling water bath.

Composition of different classes of Hawaiian soils.

	Dark-red soils.	Yellow and light-red soils.	Lowland soils.	Upland soils.

The following table compares the composition of two of the above soils with that of the lavas from which they were derived:

Comparison of lavas and soils.

	Silica.	Ferrie oxid.	Alumi- numoxid.	Calcium oxid.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Normal lavas (solid)	47.58	15.02	19.92	8.88
Normal lavas (weathering)	40.35	20.52	25.23	8.11
Dark-red soils	31.45	29.78	26.94	.57
Tufa lavas	32.84	33.92	29.11	1.74
Yellow and light-red soils	23.63	43.11	18.33	.37

The analyses show that Hawaiian soils are strongly basic. As a rule the dark-red soils and the sedimentary soils are distinguished by a greater and more permanent fertility than the yellow or light-red soils.

"A comparison of American rocks with Hawaiian lavas, and of the soils respectively derived from them, have shown that the soils of these islands are totally different in type from the soils of the United States, which is set forth by the great differences in physical properties and chemical composition. Relatively speaking, the soils of these islands are in their youth, and the soils of the United States and of Europe in a state of old age."

Availability and loss of the elements of plant food in Hawaiian soils.—For the purpose of ascertaining the availability of the fertilizing constituents in Hawaiian soils the solubility in water and in 1 per cent citric acid of the lime, potash, and phosphoric acid in samples of 30 typical soils was determined.

"In the estimation of elements soluble in water 200 gm. of the field sample (not fine earth) was put into a closed funnel, with a ground-glass cover, and treated with 1,000 cc. of water for 48 hours, the water percolating through slowly, and then returned upon the soil and continued for the time stated.

"In determining the elements soluble in 1 per cent citric acid solution 200 gm. of the field sample was put into a 2-liter bottle with 1,000 cc. of the 1 per cent citric acid solution; the bottle was gently shaken every 15 minutes during the day portion of 24 hours, and at the end of this time filtered off."

The average results in percentages and pounds per acre are as follows:

Solubility of soil constituents in water and in 1 per cent citric acid.

	Soluble in water.	Soluble in citric acid.
	<i>Per cent.</i>	<i>Per cent.</i>
Upland soil:		
Lime	0.0032	0.0940
Potash0031	.0250
Phosphoric acid0001	.0035
Lowland soil:		
Lime0054	.1330
Potash0047	.6380
Phosphoric acid0003	.0046

"By far the most striking result from the action of a 1 per cent solution of citric acid upon the soil is the enormous proportion of the lime and also of the potash dissolved."¹

¹ In connection with the tests of availability of the fertilizing constituents in the soils a series of observations was made on the relative sensibility of plants to acidity in soils, an account of which has already been given (E. S. R., 10, p. 128).

The conclusion was reached from this work that "the use of a 1 per cent solution of citric acid does not assist us very materially more than concentrated hydrochloric acid in actually reaching a duplication of the measure of solvent activity proceeding in nature, nor thus in estimating the proportion of the soil elements that are immediately available as plant food."

It was believed that the use of weaker solvents acting for longer periods would give more satisfactory results. After various preliminary tests the following method was adopted:

"Exactly 200 gm. of soil was put into the ordinary 2-liter acid bottles, having ground-glass stoppers, and 200 cc. of the solvent added. This volume was found to be just enough about to saturate and immerse the soil, without any great excess of the solvent solution being present, which was guarded against.

"Twenty bottles were taken and charged with 200 gm. of soil and 200 cc. of solvent, as already stated. Ten of these bottles were given to observations on upland (maka) soils, and the remaining 10 bottles to corresponding observations on lowland (makai) soils.

"Each series of 10 bottles was further divided into 2 groups of 5 bottles each. The one group was to furnish data setting forth the results of the continued action of a $\frac{1}{10}$ per cent solution of [citric] acid, and the second group of a $\frac{1}{50}$ per cent solution of acid upon the same soil. . . . One bottle from each of the 4 groups, containing 5 bottles each, was selected for testing and controlling the acidity of the bottles in the 4 groups. . . .

"The control of the acidity of the solutions was made by the use of a $\frac{1}{500}$ normal solution of sodic hydrate. Every fourth day 25 cc. of solution was drawn with a pipette from each of the 4 'test bottles' and the remaining acidity of the solution determined, when enough citric acid was added to restore the acidity of the solutions in each bottle in all the groups to the original strength."

The results obtained by this method are given in the following table:

Solubility of constituents of upland and lowland soils in water and in citric acid of different strengths.

"The most apparent result of the continued action of the dilute acid is seen in the effect upon the phosphoric acid, and more notably upon the iron."

"[In another series of experiments] the volume of water that the soils could absorb was determined. That volume known, enough citric acid was dissolved in it to make it exactly a $\frac{1}{10}$ per cent solution, and the solution was applied to known weights of the upland and lowland soils, respectively, as follows: Three hundred and ninety grams of water-free soil was put into beakers of 500 cc. capacity. . . . One-half of the solvent was applied through tubes [reaching to the bottom of the beakers], by which means the solution went to the bottom of the soil and rose upward by capillarity, and the other half was applied at the top, somewhat later, which descended by gravity to meet the rising volume, thus securing the most even distribution throughout the soil. The weight of each beaker was taken at the time of the first application, when exactly the volume of solution was added to saturate the soils. Every fourth day the weights of the beakers were retaken, the volume of water that had been evaporated ascertained, and a volume equal to that lost by evaporation was added to each beaker, and in this added water enough acid was dissolved to [restore the original acidity of the solution]. This was done at intervals of 4 days and continued for 120 days." The solvents used in these experiments were $\frac{1}{10}$ and 1 per cent solutions of citric acid and $\frac{1}{10}$ per cent solution of asparagin.

Similar experiments, lasting 130 days, were made with a different soil in galvanized iron pots holding 25 lbs. of soil. The results obtained in the latter experiments are summarized in the following table:

Solubility of soil constituents in water and in citric acid of different strengths.

	Calcium oxid.	Potas- sium oxid.	Phos- phoric acid.
Soluble in water:	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>

After treatment with 1 per cent acid.....	.5056	.0543	.1482

“Little change was wrought by the action of the solvents in the amounts of lime and potash soluble in water. . . . We see, however, that the amounts of lime and potash rendered soluble in 1 per cent citric acid are enormous, even in comparison with the large proportions soluble in that solvent in the natural soil. There are features in the behavior of the potash which attract special attention. It is seen that less potash is found soluble in 1 per cent citric acid after the action for 130 days of the 1 per cent solvent than where the $\frac{1}{10}$ per cent solvent was used. This behavior is also repeated in the beaker series of experiments with the lowland soil. Also the phosphoric acid gives peculiar results of the same nature. In every example the soils acted upon for 130 days by the stronger solvents showed less phosphoric acid soluble in 1 per cent citric acid after than before the action. These peculiar results are bound up with the question of resorption.”

To further study the question of resorption the following experiments were made:

“As a first test a given volume of a solution, which had been obtained by treating a soil with a dilute solution of citric acid, containing known amounts of given elements, was passed through a new quantity of the same soil. A second test consisted in passing another but a similar solution, which had been obtained by the action of a dilute citric acid solution upon the soil, through a totally different soil. . . .

“In the first test the result of passing the solution through the same soil was to increase its lime, to double its potash, and to reduce its phosphoric acid content. . . . In the second test, despite the very high potash content of the second soil, that soil took one-half of the potash out of the solution on its passing through; also the same soil, although its content of phosphoric acid was only one-fourth as large as that of the first soil, did not absorb any phosphoric acid from the passing solution.”

Similar experiments on mixed soil are reported which show—

“(1) That the result of continuing to pass the solution through the soil from which it had been obtained was merely to dissolve out more of the several elements, excepting phosphoric acid.

“(2) [When the extract was neutralized with sodium carbonate before being passed through the fresh soil there was] an emphatic absorption by the fresh soil of all elements, notably of the lime, silicic acid, and iron. This is in particular agreement with observations upon the action of dilute citric acid upon neutral soils in distinction from the action of the same solvent on acid soils.

“(3) In the absence of the carbonic acid, furnished by the carbonate of soda, the lime and also the potash continue to increase in the solution when it is passed through the fresh soil. But almost one-half of the silica and phosphoric acid are taken out of the solution by the fresh soil with a notable amount of iron and alumina bases.”

The average composition of the water of discharge of the Hawaiian Islands is given, and the losses from soils in drainage are discussed, it being claimed that it is erroneous to assume that “the composition of sea water represents the relative amounts of elements removed from the land and carried into the ocean by water.”

A study was made in this connection of the relative proportion of soil constituents soluble in 1 per cent solutions of different acids. The results are given in the following table:

Elements dissolved by the action of one per cent solutions of different acids in twenty-four hours.

Acids.	Calcium oxid.	Potas- sium oxid.	Phos- phoric acid.	Ferrie and aluminic oxids.	Silica.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>

Oxalic0170	.0226	.0106	.5430	.2330

A comparison of amounts of soil constituents soluble in dilute acids with those removed by crops and in drainage water "shows that the elements lime, potash, and phosphoric acid that are being lost to the land have been and are being removed by the waters of discharge and by cropping in the same relative proportions. . . . Aspartic acid acts upon and dissolves the constituent elements of the soil in almost the exact relative proportions that those elements are removed by cropping and the waters of discharge. . . .

"Analyses of the upland soils show that under the action of 20 years' cropping and cultivation, and during the time of the production of 10 crops of cane, 40.2 per cent of lime, 16.6 per cent of potash, and 2.02 per cent of phosphoric acid have been actually removed from the land. As a result of the action of a 1 per cent solution of aspartic acid upon the upland soils for a period of 24 hours there were removed 40.2 per cent of lime, 18.1 per cent of potash, and 2.02 per cent of phosphoric acid; which amounts of material are almost exactly equal to the amounts of the same materials removed from the same soils by 20 years of cropping and during the production of 10 crops of cane."

On the presence of sulphurous acid in the air of the Tharand forests, H. WISLICENUS (*Tharand. Forst. Jahrb.*, 48 (1898), pp. 173-184).

Tobacco soils, M. WHITNEY (*U. S. Dept. Agr., Farmers' Bul. 83*, pp. 23, fig. 1).—This bulletin discusses in a popular way "part of some preliminary work which has been done in the examination of the soils of the principal tobacco districts of the country." The topics treated are climate and distribution of tobacco; soils of the several districts, including northern cigar-tobacco soils (Connecticut Valley, Pennsylvania, Ohio, and Wisconsin); southern tobacco soils (western Florida and the Florida peninsula); bright-tobacco lands; manufacturing-tobacco lands on the Atlantic; white-burley lands of Kentucky and Ohio; export-tobacco lands of Kentucky and Tennessee; the water content of northern cigar-tobacco soils, Florida tobacco soils, soils of the manufacturing and export tobacco districts; and control of the water supply of the soil.

Report on the composition of the soils of Carmargue, G. CASTINE (*Bul. [Min. Agr. France]*, 16 (1897), No. 4, pp. 614-665; 5, pp. 798-838; *Ann. Sci. Agron.*, 1898, I, No. 2, pp. 240-320; 3, pp. 321-370).—This is an exhaustive study of the soils along the Rhone in this region, special attention being given to an investigation of the nature of the alkaline soils (including a note by E. W. Hilgard on the analysis of the efflorescences of alkali soils).

On the reduction of nitrates in arable soil, P. P. DEMÉRAIN (*Ann. Agron.*, 24 (1898), No. 3, pp. 130-134).—Experiments are reported in which the influence of different amounts of starch (1 and 2 per cent) and straw (1 per cent) on nitrification was determined in 2 soils. The nitrates uniformly decreased in the soil to which starch was added. With straw, however, the nitrates first decreased slightly and then gradually increased. The bearing of these results on the work of Wagner

¹ See also U. S. Dept. Agr., Division of Soils Bul. 11 (E. S. R., 9, p. 1035).

and Schneidewind (E. S. R., 8, pp. 761, 873; 9, p. 738) is discussed. It is claimed that the denitrifying action of manure and litter in the soil is insignificant unless these materials are applied in excessive amounts.

Soil bacteria with special reference to soil inoculation, R. S. MACDOUGALL (*Trans. Bot. Soc. Edinburgh, 1898, pp. 25-40*).

Some features of bacterial life in the soil, C. LOVÉN (*Landtmannen, 9 (1898), No. 24, pp. 380-383; 25, pp. 397-401*).

FERTILIZERS.

The home-mixing of fertilizers, C. E. THORNE (*Ohio Sta. Bul. 93, pp. 269-289*).—This bulletin discusses, in a popular manner, the following topics: The chemistry of fertilizers; carriers of nitrogen, phosphoric acid, and potash; the manufacture of fertilizers—the object of acidulation, the acidulation of tankage; the fertilizer trade; does home-mixing save only the cost of mixing; some objections to home-mixing; and the valuation of fertilizers. An account is also given of an experiment in which a comparison was made “of a few standard brands of factory-mixed fertilizers with home mixtures, made from tankage, acid phosphate, and muriate of potash, in such manner as to duplicate, as nearly as possible, the percentage composition in ammonia, available and total phosphoric acid, and potash claimed for the proprietary brands.”

“The experiment was located at the northeastern substation, the soil of which is the heavy, white clay of that region. . . . A tract of apparently uniform land was selected and divided into three sections of 20 plats each, . . . the plats containing one-twentieth acre each, and a rotation was planned to include the three crops—corn, wheat, and clover, to follow each other in a 3-year course. To start the rotation [the first and second], sections were planted in corn and [the third] section was sown in soja beans, in order to have a leguminous crop preceding the corn crop of the second year. [The first and second] sections were both fertilized according to plan, thus giving a duplicate test the first year. This proved to be the more important, as [the first] section was found to be in much poorer condition than [the second] section, the latter section having grown clover the previous season.”

While the season was unfavorable to the growth of corn, the results obtained “show as conclusively as a single season’s work can show that there is no superiority in the factory-mixed fertilizer over the home mixture of equivalent composition, while the cost of the fertilizer is largely reduced by home mixing.”

Bone superphosphate, F. POQUILLON (*Monit. Sci., 12 (1898), pp. 408, 409; abs. in Jour. Soc. Chem. Ind., 17 (1898), No. 7, pp. 679, 680*).—It is shown that the determination of nitrogen can not be relied upon to distinguish between bone superphosphate and mineral superphosphate in cases where the latter are combined with nitrogenous matter. The author found that when bones which had been treated with hot water, carbon bisulphid, or light petroleum were converted into superphosphate by treatment with acid an additional amount of fat was set free. In superphosphate made from bones treated with hot water the amount of fat was from 10 to 12 per cent and from bones treated with petroleum 6.5 per cent of the phosphoric acid. Fat determinations in the nitrogenous substances which are likely to be combined

with mineral superphosphate in mixed fertilizers showed that there was no practicable combination of them with the superphosphate which would give a product containing as high a percentage of fat as the bone superphosphate. The fat determination therefore offers a means of distinguishing between the two classes of superphosphates.

Permanency of effect of lupines as green manure, L. GRANDEAU (*Jour. Agr. Prat.*, 1898, II, No. 43, pp. 590, 591).—The author's experiments confirm those of Schultz-Lupitz in showing that lupines exert an effect on crops for at least 2 years after turning under.

On green manuring, RUMPER (*Ueber Gründüngung*. Schöneberg-Berlin: Stahel, 1898, pp. 48).

Contribution to the knowledge of the bacteria in barnyard manure which decompose nitrates, KRENZ and M. GERLACH (*Jahresber. Landw. Vers. Stat. Jersitz-bei-Posen*, 1897-98, pp. 13-20).

Molasses as a fertilizer, P. BÔNAME (*Rap. Ann. Sta. Agron. [Mauritius]*, 1897, pp. 10, 11).—The value of molasses as a fertilizer is briefly discussed and the results of 5 analyses are reported, from which the following table is calculated:

Fertilizing constituents per 100 gallons of molasses.

	Nitrogen.	Phosphoric acid.	Potash.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Sample 1	4.75	1.33	27.00
Sample 2	7.00	.58	22.00
Sample 3	7.83	.66	22.25
Sample 4	6.16	.75	22.06
Sample 5	5.25	.75	19.30

Investigations on the action of sulphate of ammonia and nitrate of soda, G. KLOEFFER (*Untersuchungen über die Wirkung des schwefelsauren Ammoniaks und des Chilisalpeters*. Essen: C. D. Baedeker, 1898, pp. 59, figs. 11).—Numerous experiments by the author and by other investigators with different crops on a variety of soils are cited to show that sulphate of ammonia is as effective on certain classes of soils and on the majority of crops as nitrate of soda. Sulphate of ammonia gives best results on basic soils and should be used on soils deficient in bases only in connection with lime in some form—marl, burnt lime, or Thomas slag. The desirability of more completely collecting the sulphate of ammonia produced by coke ovens, with a view to cheapening this valuable domestic source of nitrogen, is strongly urged.

The production and consumption of Thomas slag and superphosphate in the world, MAIZIÈRES (*L'Engrais*, 13 (1898), No. 43, pp. 1019, 1020).—It is estimated that the production of superphosphate in 1897 was 4,000,000 tons, of slag 1,400,000 tons. The average consumption per hectare of slag in different countries is given as follows: Austria 2.41, Russia 3, Italy 7.85, France 12.80, Germany 29.57, England 40.25, and Belgium 101.87 kg.

Ground limestone in agriculture, N. HEILBRAN (*Das Kalksteinmehl im Dienste der Landwirtschaft*. 1898, The Author; rev. in *Ztschr. Fleisch u. Milchhyg.*, 9 (1898), No. 2, p. 37).

FIELD CROPS.

Field experiments at the experiment farm at Lauchstädt in 1895 and 1896, M. MAERCKER (*Landw. Jahrb.*, 27 (1898), No. 1-2, pp. 82-174).—This work consisted of fertilizer experiments on meadows and with sugar beets, barley, and alfalfa; variety tests of different field

crops; a test of legumes as catch crops on loam soils; a comparison of different methods of harvesting alfalfa and clover; a test of growing sugar beets after alfalfa; and a study of the influence of different crops on the moisture content of the soil. The cultivation of the crops and meteorological conditions of the seasons are described in detail and the results given in tabular form.

Experiments with sugar beets (pp. 82-94).—The object of these experiments was to compare a number of varieties and ascertain whether a top-dressing of sodium nitrate would have an injurious effect on the sugar content of the beets and whether certain varieties were more sensitive to this treatment than others. The field on which the experiments were conducted contained 11.19 acres and was divided into 6 plats, which were fertilized as follows: Plat 1 received 35.68 lbs. soluble phosphoric acid and 356.84 lbs. nitrate of potash per acre at planting time (April 27); plat 2, 35.68 lbs. soluble phosphoric acid and 178.42 lbs. nitrate of potash per acre at planting time; plat 3 received no fertilizer; plat 4, 178.42 lbs. nitrate of potash per acre on June 29, but no phosphoric acid; plat 5 (a check plat) was fertilized the same as plat 1; and plat 6 received 35.68 lbs. soluble phosphoric acid and 133.81 lbs. nitrate of potash at planting time and the same amount of nitrate of potash as a top-dressing on June 25. Owing to abnormal conditions, the variety test was abandoned. The smallest amount of leaves produced by any variety was 8,653 lbs. per acre and the largest amount 12,266 lbs. There was no discernible relation between the yield of leaves and the yield of beets, but there seemed to be a connection, although not quite regular, between the amount of leaves and the sugar content of the beets. Some of the more important varieties, averaging 11,874 lbs. of leaves per acre, contained on an average 17.52 per cent of sugar in the beet, and two varieties yielding 9,867 lbs. of leaves per acre had an average sugar content of 16.84 per cent, while the varieties producing only 8,653 lbs. of leaves per acre contained only 14.8 per cent of sugar in the beet. The entire structure of the plant and the amount of chlorophyll and its condition are considered equally important with the leaf surface; and as the sugar content of the beet depends on the amount of carbon dioxid assimilated, other things being equal, the amount of leaf surface would influence the sugar content. The sugar content of the beets was very satisfactory, although the season was wet and there was but little sunshine. During the months of April to October, inclusive, the rainfall was 404.6 mm. (nearly 16 in.) and the amount of sunshine for the months of May to October, inclusive, aggregated only 696 hours and 43 minutes. The amount of sunshine during August and September was especially low, aggregating only 128 hours 3 minutes. The longest time the sun shone on any September day was 4 hours 10 minutes. The average temperature during April to October, inclusive, was 57.6° F.; the highest average temperature for any month, 68.74°, was reached in

June. The author believes the high sugar content obtained was due to the continuous and regular growth of the beets during the entire season, and that a regular distribution of temperature and rainfall is more conducive to the production of an extremely high sugar content than a larger amount of heat.

The results of the fertilizer experiment showed that the application of 35.68 lbs. soluble phosphoric acid per acre did not increase the yield of beets and had no effect on the sugar content. The results with nitrogenous fertilizers were as follows: No nitrogen, 15.625 tons of beets per acre with a sugar content of 17 per cent; 178.42 lbs. potassium nitrate, 18.221 tons per acre with a sugar content of 17.1 per cent; and 356.84 lbs. potassium nitrate, 19.318 tons per acre with a sugar content of 16.63 per cent. The results did not show that the top-dressing had any influence on the sugar content of the beets.

Fertilizer experiments and variety tests with barley (pp. 94-119).—The field contained 11.18 acres. A test was made of 2 varieties of Hanna barley (Original and Benkendorfer) and 4 varieties of Chevalier (Trotha Saale, Heine Improved Chevalier, Heine Golden Melon, and Richardson Chevalier). The Benkendorfer Hanna barley is the original Hanna grown at Benkendorf for a number of years. The original Hanna produced the largest yield of grain, 64.52 bu., being 4.44 bu. per acre more than the average yield of the Chevalier varieties; while the Benkendorfer Hanna yielded only 1.02 bu. per acre more. The Chevalier varieties were about equally productive. The average yield of straw of the Chevalier varieties was 4,044 lbs. per acre and of the Hanna varieties 3,637 lbs. Taking the yield of grain and straw into consideration, the author believes Heine Improved Chevalier barley one of the best standard varieties. It is thought the Hanna varieties, like most varieties producing small amounts of straw, possess the advantage of requiring smaller amounts of moisture and plant food, and will be adapted to soils on which the profitable culture of the heavier straw-producing varieties is doubtful. These varieties are also 5 or 6 days earlier in maturing than the Chevalier. The following table shows some points of comparison between the two kinds of barley:

Comparison of the crops of Hanna and Chevalier varieties of barley.

	Protein content.	Weight of 1,000 kernels.	Weight per bushel.	Mealy grains.
	<i>Per cent.</i>	<i>Grams.</i>	<i>Pounds.</i>	<i>Per cent.</i>
Hanna barley (average of 2 varieties).....	7.71	44.0	49.299	59
Chevalier barley (average of 4 varieties).....	8.01	42.2	49.010	52

The fertilizer tests were made with applications of 535.26 lbs. kainit, 89.21 and 178.42 lbs. nitrate of soda, and 26.76 lbs. nitrogen in the form of crude Peruvian guano per acre. The object was to observe the effect of potash and nitrogen. On some plats the nitrogenous fertilizers

were applied in conjunction with kainit while in others no potash fertilizer was used. The soil contained approximately 0.25 per cent of potash. Some of the results obtained are as follows:

Average increase in yield of grain per acre of fertilized over unfertilized plats of barley.

Kainit, 535.26 lbs. per acre:	Pounds.
Hanna, average of 2 varieties.....	53.52
Chevalier, average of 4 varieties.....	405.90
Kainit, 535.26 lbs., sodium nitrate, 89.21 lbs. per acre:	
Hanna, average of 2 varieties.....	401.44
Chevalier, average of 4 varieties.....	112.73
Kainit, 535.26 lbs., sodium nitrate 178.42 lbs. per acre:	
Hanna, average of 2 varieties.....	292.60
Chevalier, average of 4 varieties.....	33.00

It is shown by these and other experiments that kainit, when applied with nitrogenous materials, not only increased the yield, but also improved the grain, the starch content and weight of the grain, and increased the percentage of mealy grains. Both applications of sodium nitrate were found profitable. The protein content was not increased and the quality of the grain was not impaired.

Results obtained from applications of nitrate of soda.

Fertilizer per acre.	Yield per acre.		Increase per acre over unfertilized plats.		Protein content.	
	Grain.	Straw.	Grain.	Straw.	Without kainit.	With 535.26 lbs. kainit per acre.
	<i>Bushels.</i>	<i>Pounds.</i>	<i>Bushels.</i>	<i>Pounds.</i>	<i>Per cent.</i>	<i>Per cent.</i>
No nitrogen	49.28	3,025.73			8.42	7.41
Sodium nitrate, 89.21 lbs.....	59.93	3,914.53	10.67	888.79	8.45	8.10
Sodium nitrate, 178.42 lbs.....	64.16	4,358.17	14.97	1,332.44	8.04	7.83

The plats fertilized with Peruvian guano yielded on an average 44 lbs. of grain and 308 lbs. of straw less than the plats which received the nitrate of soda, but the grain from the guano plats was heavier and contained less protein, more starch, a larger percentage of mealy grains, and better kernels. Each application furnished 26.76 lbs. of nitrogen per acre. Potash applied in conjunction with guano had no influence either on the yield or quality of the grain.

Variety tests (pp. 119-150).—Comparative tests were made with varieties of wheat, rye, oats, barley, peas, fodder beets, and potatoes. The preparation of the soil is described and the results obtained are given in tables.

Sixteen varieties of winter wheat, including 8 square head and 2 bearded varieties, were tested. One of the varieties classed with the square head sorts, a cross between a square head variety and an early maturing American variety, and known as Rimpau Bastard wheat, produced the largest yield of grain and was, with Mold Red Prolific, the earliest maturing variety in the experiment. The periods

of growth of the different varieties varied from 294 to 316 days. The square head variety grown in the vicinity of the experiment farm for a number of years yielded 8.89 bu. of grain and 996 lbs. of straw per acre less than the recently improved varieties of square-head wheat. The protein content of the square-head varieties was found to be quite low, being 9.21 per cent in the grain, 1.22 per cent in the straw, and 2.47 per cent in the chaff. The total amount of the protein obtained from equal areas was smallest in the square-head varieties. The author states that modern breeding has not yet produced a variety of square-head wheat which produces large yields and also has a high gluten content.

Of winter rye 7 varieties were grown. The best yielding varieties were Heine Improved Zeelander and Petkuser, yielding 52.09 and 51.61 bu. per acre, respectively. The Zeelander variety ripened in 282 and the Petkuser in 277 days. The average number of haulms per plant varied from 5.7 to 6.8 among the different varieties, being 6.3 for Heine Improved Zeelander, 6.4 for Petkuser, and 6.8 for the Göttinger variety. The Heine Zeelander and Petkuser varieties contained 8.75 and 8.22 per cent of crude protein, respectively. The author states that modern improvement of varieties seems to increase the yield by increasing the size of the grain and consequently the starch content, and that, as a result, the new varieties are poor in protein.

A comparative test was made of 7 varieties of spring wheat grown after sugar beets and alfalfa. The plats were fertilized at the rate of 26.76 lbs. of soluble phosphoric acid and 178.42 lbs. potassium nitrate per acre. The wheat was sown in drills March 27 at the rate of 2.02 bu. per acre. The yields are given in the following table:

Comparative yields of varieties of spring wheat.

Varieties.	Grown after sugar beets.				Grown after alfalfa.			
	Grow- ing period.	Yield per acre.		Ratio of grain to straw.	Grow- ing period.	Yield per acre.		Ratio of grain to straw.
		Grain.	Straw.			Grain.	Straw.	
	<i>Days.</i>	<i>Bus.</i>	<i>Lbs.</i>		<i>Days.</i>	<i>Bus.</i>	<i>Lbs.</i>	
Bordeaux.....	141	41.39	3,969.8	1:1.60	141	47.07	4,506.8	1:1.60
Nöe.....	138	40.64	4,126.8	1:1.69	137	47.42	4,952.9	1:1.74

The wheat grown after alfalfa gave the best yields, but the grain did not fill as well as that grown after sugar beets.

A four-rowed variety of summer barley, grown on land which was in sugar beets the year previous, yielded 53.84 bu. of grain and 3,761 lbs. of straw per acre, but the grain produced was of poor quality.

Six varieties of field beets, a yellow and red sort each of the Oberndorfer, Eckendorfer, and Leutewitzer varieties, were grown after

alfalfa. The plants were fertilized with 356.84 lbs. of nitrate of soda per acre, and some plats received phosphoric acid at the rate of 53.52 lbs. per acre in addition. One-half of the nitrate of soda was applied as a top-dressing. The results showed that the application of phosphoric acid increased the protein content of the beets, and that the red sorts gave greater yields than the yellow. The data for the different varieties are given in the following table:

Composition and yield per acre of different varieties of sugar beets.

Varieties.	Yield per acre.		Composition of the beets.			Food material per acre in the beets.		
	Beets.	Leaves.	Dry matter.	Crude protein.	Nitrogen-free extract.	Dry matter.	Crude protein.	Nitrogen-free extract.
	<i>Tons.</i>	<i>Tons.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Red Eckendorfer	44.167	2.337	10.54	0.89	8.80	9,310.8	785.9	7,773.7
Yellow Eckendorfer	38.792	3.192	10.83	.98	8.99	8,112.7	734.1	6,975.3
Red Lentewitzer	35.685	5.275	14.38	1.05	12.40	10,263.6	749.3	8,849.6
Yellow Lentewitzer	34.589	5.319	14.45	1.06	12.47	10,012.0	734.1	8,626.6
Red Oberendorfer	35.007	4.926	13.08	1.12	11.43	9,158.2	784.1	8,003.0
Yellow Oberendorfer	34.245	4.003	13.08	1.12	11.43	8,958.0	767.2	7,828.1

Two early and 7 late varieties of oats were tested, and the results are discussed and tabulated. The plats received 89.21 lbs. potassium nitrate per acre, one-fifth being applied as a top-dressing. The results obtained are given in the following table:

Results of variety tests with oats.

Varieties.	Growing period.	Yield per acre.	
		Grain.	Straw.
	<i>Days.</i>	<i>Bushels.</i>	<i>Pounds.</i>
Early varieties:			
Milton	123	102.18	4,580
Duppauer	120	93.84	3,791
Late varieties:			
Trauben	123	104.09	4,510
Heine ertragreichster	126	101.93	4,228
Strube Schlanstedter	127	115.25	4,755
Beseler	127	106.09	5,254
Anderbecker von Rimpau	127	107.66	4,782
Bestehorn Überfluss	129	101.93	4,307
Lentewitzer Gelbhafer	129	110.56	4,387

In protein content the varieties differed immaterially, but Lentewitzer Yellow contained 5.12 per cent of fat, being nearly 1 per cent more than found in any other variety.

Among 16 varieties of potatoes, Professor Maercker produced the largest yield of tubers and starch, being 458.4 bu. of tubers and 5,225.9 lbs. of starch per acre. Next in order of productiveness was the variety Geheimrat Thiel with a yield of 427.8 bu. of tubers and 4,877 lbs. of starch per acre.

Growing sugar beets after alfalfa (p. 151).—Sugar beets on plats which had grown alfalfa the year previous were not only less productive, but

also lower in sugar content than beets grown on plats used for sugar beets the year before.

Fertilizer experiments on meadows (pp. 151-155).—A swampy meadow was drained and divided into 5 plats, 1 of which was left unfertilized, while 2 were fertilized with kainit and 2 with kainit and ground Thomas slag. No effect of the application was noticeable during the first year. It was found that on the plat which had received potash and phosphoric acid there was a greater admixture of leguminous plants, and consequently the protein content of the hay was increased.

A fertilizer experiment with alfalfa (pp. 155-157).—A field on which alfalfa had been grown for four years in succession was divided into three equal plats. One plat was left unfertilized, one received an application of 535 lbs. per acre of ground Thomas slag, and the other an application of 892 lbs. per acre of kainit and 535 lbs. of ground Thomas slag. The results do not show that the fertilization was very effective, but the following year the effect of the fertilizers was shown in the growing crop, the results of which will be reported later.

Experiments with legumes as catch crops on clay soils (pp. 157-163).—A barley field, after the crop had been removed, was divided into plats and sown with 6 different mixtures of legumes. The seed on some of the plats was inoculated with Nitragin.

The mixtures of beans, peas, and vetch and beans, and sand vetch and vetch made a good growth. The mixtures containing lupines made a less satisfactory growth, and the mixture of lupines, Victoria peas, and Lathyrus made a very poor growth. On the Nitragin plats many well-developed plants of lupine with normal nodule formations on the roots were found, but on the uninoculated plats normal plants of lupines with well-developed nodules were very few. The largest amount of nitrogen gathered per acre was by the mixture of beans, Victoria peas, and vetch, 137.76 lbs., which is equal to the amount contained in 892 lbs. of nitrate of soda, and the amount of organic matter produced equaled the amount furnished in 25.35 tons of stable manure. The results in 5 cases are but slightly in favor of inoculation with Nitragin, while in one case the inoculation produced no effect whatever. An oat crop grown after legumes made a remarkable growth, but the results have not yet been reported.

Methods of curing clover and alfalfa (pp. 163-170).—The report of this work has been abstracted from another source (E. S. R., 9, p. 439).

Influence of different crops on moisture content of the soil (pp. 170-174).—An experiment was conducted to ascertain the influence of different crops on the moisture content of the soil. The moisture content of fields of sugar beets, peas, winter wheat, potato, and oats was determined twice per week throughout the season from May 21. Sugar beets and potatoes lowered the moisture content comparatively little during the early part of the season, while with winter wheat and oats there was a much greater decrease in the percentage of moisture.

Throughout the experiment it was shown that the moisture requirement of peas was not as great as for the other crops. When the crops of peas and wheat had been removed the wheat-stubble field contained only 9.41 per cent of moisture to 14.9 per cent in the pea-stubble field. The moisture requirements for oats and alfalfa appeared to be greater than for potatoes.

Corn culture in the South, S. M. TRACY (*U. S. Dept. Agr., Farmers' Bul. 81, p. 21*).—The author discusses the soil and its preparation, crop rotations, fertilizers, varieties, the planting, cultivating, harvesting, and storing of the crop, and saving the seed. The results of experimental work with corn at various Southern experiment stations are given in connection with the discussion of the different operations and practices. In the discussion of varieties for the South it is advised that when corn is grown for ordinary purposes it should be a dent variety of local origin, ripening in from 150 to 170 days; the stalks should have well-developed roots, and average nearly two ears each of uniform diameter throughout, well filled at both ends and pointing downward when ripe; the cobs should be small in proportion to the size of the ear, and the individual grains should be long and so broad at the upper end as to leave only a slight depression between the rows.

“White varieties will usually make a heavier yield than colored varieties, though many colored varieties are more vigorous and hardy than some of the more prolific white varieties.

“It is as important to take seed from the best stalks as from the best ears, and whatever variety may be preferred, every ear which is selected for seed should be taken from a stalk which in size, habit of growth, and number of ears approaches closely to what is the desired form for that variety.”

The cost of the production of corn and oats in Illinois in 1896 (*Illinois Sta. Bul. 50, pp. 53-76*).—The results presented in this bulletin were obtained from an investigation of the expense of raising the corn and oat crops of 1896 in Illinois. The estimate of the cost of production of these crops received from farmers throughout the State are tabulated.

Of 900 circulars distributed to obtain the necessary data 316 were returned with answers. Of these 274 and 170 were used in calculating the cost of producing the crops of corn and oats, respectively. The average yield of corn per acre on the farms taken into consideration was 54 bu. and of oats 34 bu. The yield of corn was somewhat above the average, while that of oats was considerably below the average yield. The cost of production as determined here “is the average sum of the expenditures on all the processes involved in production, from the preparation of the soil to the delivery at the elevator, including the wages of the farmer himself, whether owner or renter. A proper allowance is made for time lost and for maintenance of team during idleness, interest on investment, including rent and allowance for depreciation of tools and machinery.” On this basis the calculated cost of production of corn was 19.5 cts. per bushel and \$10.59 per acre, and the cost of production of oats 21 cts. per bushel and \$7.76 per acre.

A report on flax culture for seed and fiber in Europe and America, C. R. DODGE (*U. S. Dept. Agr., Office of Fiber Investigations Rpt. No. 10, pp. 80, figs. 5, pls. 1*).—This report describes the different kinds of flax and the methods of flax growing practiced in Belgium, France, Poland, Ireland, and Russia, and reviews in general the work in the United States. The Loppens de Swarte system of retting and its advantages are pointed out. In considering flax culture in the United States, the author reviews the experiments made at the experiment stations and elsewhere and gives cultural directions, including selection and preparation of the soil, use of fertilizers, rotation of crops, sowing, harvesting, retting, and cleaning.

An experiment in flax culture made in 1895 in the vicinity of Puget Sound, Washington, is reported. The flax was grown from Riga seed, the 4 plats containing about 5 acres. The seed was sown too late and drought interfered with the growth of the crop, especially on sandy soil. Plat 1, containing $1\frac{1}{4}$ acres of sandy clay loam river bottom land, was sown at the rate of 2 bu. of imported Riga flax on May 18. No fertilizers were applied. The yield was at the rate of 3,865 lbs. of clean straw and 17 bu. of clean seed per acre. The conditions on plat 2 were identical with those on plat 1, but the flax was sown at the rate of $1\frac{1}{2}$ bu. per acre. The yield on this plat was at the rate of 3,557 lbs. of clean straw and 16.8 bu. of clean seed per acre.

In 1896 about 1 ton of flax straw grown in the Puget Sound region was sent to the Hilden Thread Works, Lisbon, Ireland, and there retted and scutched. The work was done under the direction of Mr. Frank Barbour, who reported the results in detail. In his report he says, "If the flax is grown and manipulated under proper conditions and by people who thoroughly understand the business in Puget Sound, we are convinced that the cultivation of it will be of greatest importance and in a short time would rival the great Belgium district of Courtraie."

Present status of flax culture in the United States, C. R. DODGE (*U. S. Dept. Agr. Yearbook 1897, pp. 471-486*).—This article contains a historical sketch of flax culture, a popular description of the more important species of flax, a discussion of European methods of culture, a comparison of the conditions of the industry in the United States and Europe, and suggestions for developing the industry of flax culture and manufacture in this country.

A report upon the grasses and forage plants and forage conditions of the Eastern Rocky Mountain region, T. A. WILLIAMS (*U. S. Dept. Agr., Division of Agrostology Bul. 12, pp. 78, figs. 30*).—This bulletin discusses the topographical features of the Eastern Rocky Mountain region, with a special consideration of the soil and the water supply. Detailed accounts of the cultivated grasses and forage plants and the more important plants native to the region are presented, the present prospect of the forage problem of the region is discussed, and methods for the improvement of ranges are suggested. An index to both common and botanical names is given.

The cultivated grasses most commonly found in the meadows and pastures of this region are timothy, redbtop, Kentucky blue grass, smooth or Hungarian brome grass, meadow fescue, and orchard grass.

"The millets and the various small grains are quite generally grown for summer forage and for hay and grain, and the sorghums, both saccharine and non-saccharine varieties, are occasionally grown for fodder. Nearly all the common clovers are successfully grown in some part of the region, alfalfa and red clover being in most general cultivation. . . . Almost without exception they are irrigated, at least for a portion of the season. . . . There are about 270 species and varieties of grasses known to be indigenous to this region. . . . The most valuable species are quite widely distributed, although occasionally a species of but local occurrence may be of considerable importance in its particular locality, as is the case with some of those occurring in the mountains."

Besides the grasses a number of native clovers, vetches, lupines, rushes, sedges, sages, and other forage plants are discussed. The native meadow and hay grasses are considered under two groups: Those growing on low-land meadows and mountain meadows, and the native pasture grasses, as those growing on the plains and on the foothills and mountains.

Leguminous forage crops, J. G. SMITH (*U. S. Dept. Agr. Yearbook 1897, pp. 487-508, figs. 8, pl. 1*).—This article gives a short historical sketch of the cultivation of leguminous crops and discusses their value for feeding and fertilizing. Red clover, alfalfa, cowpeas, soja beans, crimson clover, Florida beggar weed, field peas, Dakota vetch (*Lotus americanus*), ground plum (*Astragalus crassicaarpus*), Metcalfe bean, (*Phaseolus retusus*), and the Stolley vetch are considered at some length with reference to their culture and value.

Some Irish potato experiments, C. L. NEWMAN (*Arkansas Sta. Bul. 50, pp. 21-34*).—These experiments consisted of culture and variety tests of potatoes and the use of second-crop potatoes for seed.

For 3 years experiments were carried on with second-crop potatoes for seed and with northern-grown seed of the same varieties. The first year 2 varieties were grown, the second year 4, and the third year 7. The varieties planted for these trials were Beauty of Hebron, Bliss Triumph, Crown Jewel, Early Rose, Freeman, Puritan, Wood Earliest, and Peerless. Each set of plats contained the same number of plants. The results for each year are given in tables. The average results give northern seed the advantage in yield and earliness. The following table gives the average of each year's average for the entire series of experiments:

Second-crop seed compared with northern-grown seed—average of 3 years.

Character of seed.	Yield of mer- chantable potatoes.	Yield of culls per acre.	Total yield per acre.	Number of days from planting to maturity.
	<i>Bushels.</i>	<i>Bushels.</i>	<i>Bushels.</i>	
Northern-grown seed.....	94.91	11.19	106.10	108.54
Second-crop seed	81.29	16.04	97.34	111.67
Difference	13.62	4.85	8.76	3.13
Percentage difference.....	16.75	43.34	9.00

With but 2 exceptions the northern-grown seed proved to be superior. In 1896 Early Rose second-crop seed gave a better yield than northern seed, and Crown Jewel from second-crop seed ripened 3 days earlier than from northern seed. In general, second-crop seed was slow and irregular in starting and produced vines inferior in vigor and appearance. It was also found that potatoes from northern seed gave a better yield at different stages of growth than potatoes from second-crop seed. In 1896 the average yield of the 7 varieties from northern and second-crop seed on May 20 was 80.39 and 69.14 bu. per acre, respectively, and on June 1 89.35 and 82.75 bu. per acre.

Four plats were planted with large and small second-crop seed to compare the yields. Perfect whole tubers 2 to 3 in. in diameter were planted on plats 1 and 3, and whole tubers from $\frac{3}{4}$ to $1\frac{1}{4}$ in. in diameter on plats 2 and 4. Plats 3 and 4 were planted with cut tubers of the same size as those used on plats 1 and 2, respectively. Large whole potatoes yielded 18 per cent more than whole small seed, and the large cut tubers 15.8 per cent more than the small cut tubers.

The results of a series of culture tests were in favor of level as against ridge culture. The results are considered due largely to the drought and the sandy character of the soil. The rows were ridged 2, 4, 8, and 12 in. high and each increase in the height of the ridges resulted in a decrease in the yield.

Of 20 varieties tested, Ohio Jr., Crown Jewel, Early Six-Weeks Market, World's Fair, and Wood Earliest gave the best results.

An outlay of \$2 per acre for spraying or dusting Paris green on the plants to destroy the potato beetles resulted in an increase of 11 bu. or 13.6 per cent per acre.

Sugar beets, H. SNYDER and A. BOSS (*Minnesota Sta. Bul. 56*, pp. 377-416, figs. 4).—This bulletin gives a summary of the sugar-beet investigations in Minnesota from 1888 to 1898, a report on the work for 1897, and an outline of the proposed experiments for 1898.

From 1888 to 1898, 1,351 samples of sugar beets from different parts of the State were analyzed. The average sugar content of these samples was 14.22 per cent, with 81.2 purity.

Average results of culture experiments with sugar beets, 1888 to 1897.

	1888.	1890.	1891.	1892.	1893.	1894.	1895.	1896.	1897.
Average sugar content (per cent) ..	13.4	12.9	14.1	15.0	15.2	17.2	15.6	13.7	15.0
Average purity coefficient	83.1	79.5	80.1	84.6	84.4	86.6	85.6	81.0	83.1
Highest sugar content (per cent)...	20.3	17.9	20.4	19.1	18.4	19.4	20.6	18.2	18.3
Number of samples tested	111	55	465	185	15	14	22	25	303

The conditions which affect the sugar content of the crop are discussed at some length. In 1897 culture experiments were made at the station and by farmers throughout the State. The results are given in tables. The results obtained from sugar beets in different parts of the State under poor conditions of cultivation are reported separately.

Beets obtained in cooperative experiments carried on by 100 farmers in the vicinity of Albert Lea averaged 13.8 per cent of sugar, with a purity of 82. An experiment in seeding beets at different dates gave the following results:

Results of seeding beets at different dates.

Date seeded.	September 21.		October 28.		Average weight.
	Sugar in juice.	Purity.	Sugar in juice.	Purity.	
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	
May 15	14.0	81.9	16.5	86.0	12.8
May 15	13.9	86.9	16.5	86.4	11.2
May 27	13.7	85.6	16.6	84.3	15.2
May 27	13.1	87.3	17.7	86.0	10.0
June 5	14.2	88.8	18.2	87.0	11.6
June 5	13.8	85.2	17.9	86.0	10.8

An experiment was made by the station to ascertain the best distance at which sugar beets should be grown. The following table gives the average results of two trials:

Results of sugar beets grown at different distances.

Distance.	Sugar content.		Coefficient of purity.	Yield per acre.	Value per acre.
	In the row.	Between rows.			
	<i>Inches.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Tons.</i>	
4 inches	14	17.3	85.4	17.2	\$68.80
6 inches	14	17.7	87.6	16.2	64.80
8 inches	14	16.1	85.7	16.9	67.60
10 inches	14	15.6	84.2	16.9	67.60
4 inches	18	18.0	89.8	16.2	64.80
6 inches	18	16.8	86.8	16.6	66.40
8 inches	18	16.2	87.9	17.6	70.40
10 inches	18	16.0	84.0	17.1	68.40
4 inches	24	16.5	85.1	15.2	60.80
6 inches	24	15.7	88.6	16.3	65.20
8 inches	24	16.3	87.1	16.1	64.40
10 inches	24	16.8	87.1	15.9	63.60
4 inches	30	15.9	83.7	16.5	66.00
6 inches	30	16.0	86.9	16.5	65.20
8 inches	30	15.4	88.1	17.5	70.00
10 inches	30	14.9	80.7	15.7	62.80

There was practically no difference in the average results from the rows which were 14 and 18 in. apart, and these distances gave the best returns. There was little difference in the average results from plats on which the beets were grown 2, 4, 6, and 8 in. apart in the row. "Economy of labor would dictate that for our conditions we plant the rows 18 in. apart and thin the beets to 5 to 7 in. apart in the row."

Sugar-beet investigations of 1897, G. W. SHAW (*Oregon Sta. Bul.* 53, pp. 36, figs 14, *diagms.* 3).—Cooperative culture experiments with sugar beets in 1897 were limited to the counties of the State which seemed best adapted to the production of sugar beets and the manufacture of sugar. The results of analyses of beets from each county are given in tables and the climatic conditions of the season are compared with the normal conditions of the region and those of France and Ger-

many. The culture of the sugar beet and the conditions for manufacturing are discussed at some length.

The average results for the different counties where experiments were conducted on a considerable scale are given in the following table:

Average results of sugar-beet experiments in 4 counties in Oregon in 1897.

Counties.	Sugar in juice.	Purity.	Yield per acre.	Cost per acre.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Tons.</i>	
Union	18.5	88.5	23.7	\$11.20
Jackson	15.5	81.0	15.8
Washington	16.1	86.7	15.7	24.00
Clackamas	13.7	83.4	17.8	26.00

The average for the entire State (216 analyses) was found to be 15.24 per cent sugar in the juice, with a purity of 84.36 and an average yield of 18.54 tons per acre.

Irrigation experiments in sugar-beet culture in the Yakima Valley, E. FULMER (*Washington Sta. Bul. 31, pp. 30, fig. 1, pl. 1, map 1*).—In this bulletin the work with sugar beets at the station is reviewed and sugar-beet culture with irrigation discussed. The results of cooperative irrigation experiments with sugar beets are given in tables. A geographical and geological description of the Yakima Valley and the amount of land there reclaimed by means of artesian wells are given. Chemical analyses of soils from irrigated districts are summarized.

The averages of 68 samples from the irrigation experiments with sugar-beet culture were as follows: Sugar in the juice, 17.6 per cent; sugar in the beet, 16.7 per cent; purity, 85.2 per cent. The varieties grown were Kleinwanzlebener and Vilmorin.

Cultivation of tobacco in Sumatra, E. MULDER (*U. S. Dept. Agr., Cultivation of Tobacco in Sumatra, pp. 39, figs. 3, map 1*).—This publication is a paper on the method of cultivation of the tobacco crop of Sumatra and the physical features of the district in which the tobacco is grown. Statistics on the production and trade of Sumatra tobacco are given. The mean temperature and rainfall for each month for a number of years at Penang and Singapore and the results of mechanical analyses of Sumatra tobacco soils are given in tables. The physical features of the island, the introduction of tobacco, and the laying out and management of tobacco estates, with directions for building drying sheds and other buildings are discussed, and descriptive notes on the prevailing diseases of tobacco and the various operations in planting, cultivating, curing, and preparing the crop for market are given. The cost of growing tobacco in Sumatra is considered. The author states that a very good type of Sumatra tobacco is successfully grown in some parts of Florida, and that if special attention be given to the qualities which characterize Sumatra tobacco, namely, fine texture of the leaf and uniformity in color and length, there will be a large increase in the demand for the home-grown product.

Report of the agriculturist, W. H. BISHOP (*Delaware Sta. Rpt.* 1897, pp. 211-213).—A report is given of fertilizer experiments on rotation plats, with tabulated results. The applications of fertilizers consisted of 160 lbs. nitrate of soda, 400 lbs. acid phosphate, and 160 lbs. muriate of potash per acre. These different fertilizers were applied alone and in combinations of twos and threes, the application being made each year. On account of the poor condition of the soil, the application was doubled the first year of the experiment. Sweet corn, crimson clover, cowpeas, oats, and red clover, in the order given, have thus far entered into the rotation. The results from red-clover plats in 1897 indicated that muriate of potash is a suitable fertilizer for clover on that soil. The mixture of muriate of potash and acid phosphate was found a desirable fertilizer for cowpeas. The experiment is to be continued.

On the production of beet seed, J. F. LUNDBERG (*Laudtm. Månadsbl.*, 1898, No. 9, pp. 129-131).

Corn and its uses in America, G. ROSSATI (*Movimento Agricolo*, 4 (1898), No. 44, p. 485).

In the land of ginger—Jamaica, F. B. KILMER (*Amer. Jour. Pharm.*, 70 (1898), No. 2, pp. 65-85, figs. 6; *abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 3, p. 365).—A popular article describing the methods of cultivating and preparing ginger for the market in Jamaica and giving statistics of the crop.

Fodder and forage plants (exclusive of grasses) (*West Australian Settler's Guide and Farmer's Handbook*, 1897, pt. 3, pp. 432-491, figs. 40).—Illustrated descriptive notes are given of numerous fodder and forage plants, the bulk of the information being taken from Bulletin 2 of the Division of Agrostology, U. S. Department of Agriculture.

Cultivation of orris root in Italy (*Rpt. of Schinmel & Co.*, 1897, Oct., p. 38; *abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 1, p. 68).—A description of methods of culture and preparation for the market.

West Australian saltbushes, F. TURNER (*West Australian Settler's Guide and Farmer's Handbook*, 1897, pt. 3, pp. 418-431, figs. 9).—Notes are given on some of the native species of saltbushes and illustrated descriptions of the following: *Atriplex cinerea*, *A. halimoides*, *A. semibaccata*, *A. stipitata*, *A. vesicaria*, *Koehia planifolia*, *K. villosa*, *Rhagodia billardieri*, and *R. nutans*.

Saltbushes and their cultivation, A. MORRISON (*Producers' Gaz. and Settlers' Rec.* [*West. Australia*], 5 (1898), No. 5, pp. 359, 360).—Brief notes are given on the value of saltbushes and on methods for their propagation.

Notes on the selection of sugar cane, P. BÔNAME (*Rap. An. Sta. Agron.* [*Mauritius*], 1897, pp. 49-55).—Several experiments in selecting canes for propagating purposes are reported. In some cases canes high in sugar content produced canes richer in sugar than canes with low sugar content, while in one instance the reverse was the case. In several of the tests the progeny of the canes high and low in sugar content showed but little difference in quality. It was also shown by experiments that canes propagated from cuttings taken from the upper part of the stalk are not necessarily inferior. The canes grown from such cuttings had in some cases a higher and in others a lower sugar content than canes grown from cuttings taken from the body of the stalk. In all cases the yield was in favor of cuttings taken from the upper part of the stalk, owing, it is stated, to the fact that these cuttings make the best growth.

Composition and yield of different varieties of sugar cane, P. BÔNAME (*Rap. An. Sta. Agron.* [*Mauritius*], 1897, pp. 24-44).—The results of analyses of 61 varieties of sugar cane at different stages of growth and of a large number of seed canes are given in tables. The crop and weather conditions are briefly noted. Similar work has been previously noted (E. S. R., 9, p. 638).

Fertilizer experiments on sugar cane. P. BONAUME (*Rep. An. Sta. Agron. [Mauritius], 1897, pp. 45-48*).—Experiments on commercial fertilizers applied singly and in combination were made on 20 plats and the results obtained are here reported in tables. Nitrogenous fertilizers, dried blood, ammonium sulphate, and sodium nitrate, were most effective when applied in combination. Potash in the form of chlorid gave a larger increase in yield than when applied in the form of nitrate or sulphate.

Experiments with Nitragin during the summer of 1897. J. E. PALMER (*Tidsskr. Landtman, 19 (1898), No. 10, pp. 175-179*).—Practical testimony, on the whole favorable.

Nitragin (*Pennsylvania Dept. Agr. Bul. 31, pp. 53-56*).—Brief popular notes are given concerning this preparation and quotations are given from the publications of several who have made experiments with the substance.

The culture of tobacco. O. C. BUTTERWECK (*U. S. Dept. Agr., Farmers' Bul. 82, pp. 24*).—This bulletin gives complete directions for the culture of tobacco, discussing the following points: Selecting, saving, and sowing the seed; preparing the seed bed; and planting, cultivating, fertilizing, topping, and cutting the plants. A note on the destruction of insect pests injurious to tobacco is given.

Progress in tobacco culture. R. KISSLING (*Chem. Ztg., 22 (1898), No. 52, pp. 524, 525*).—A review of recent experiments on tobacco in different countries. The work is described in abstract form and comprises a study of a nematode disease of tobacco and fertilizer and culture experiments carried on to determine the effect upon the quality of the crop, especially its fire-holding capacity.

Wheat experiments. D. BEVERIDGE (*Agr. Gaz. Tasmania, 6 (1898), No. 1, p. 15*).—Results of a test of 14 varieties of wheat are given in a table. Smith Nonpareil and Blount Limbrigg were free from rust and The Blount and Square Head were most productive.

Winter and summer pasture in Mississippi. E. R. LLOYD (*Mississippi Bul. 50, pp. 12*).—This bulletin contains directions for the preparation of the soil for permanent pasture and notes on Bermuda grass, carpet grass, lespedeza, melilotus, hairy vetch, turf or winter oats, redtop, alsike clover, and pasture grasses. Grass mixtures suitable for pine-woods soils, yellow and brown loams, and prairie soils are suggested. The water supply of pastures is considered in a short note.

Plant culture in Denmark during 1897. K. HANSEN (*Tidsskr. Landökon., 17 (1898), No. 1-2, pp. 5-25*).

HORTICULTURE.

Horticulture: Results for 1896-97. W. C. STUBBS, F. H. BURNETTE, and E. WATSON (*Louisiana Stas. Bul. 52, 2, ser., pp. 285-332*).—This bulletin contains remarks on the seasons of 1896 and 1897, and notes and tabulated data on the following crops grown at the stations during these two years:

Vegetables.—Chinese cabbage (*Pe Tsai*), asparagus, beans, beets, Brussels sprouts, cabbages, cauliflowers, carrots, celery, sweet corn, cress, cucumbers, cantaloupes, eggplant, endive, kohlrabi, lettuce, leeks, watermelons, mustard, okra, onions, peas, parsley, peppers, Irish potatoes, sweet potatoes, pumpkins, radishes, spinach, tomatoes, squashes, and turnips. **Fruits.**—Apples, figs, pears, peaches, plums, Japan persimmons, grapes, cherries, almonds, apricots, nectarines, pomegranates, medlars, goumi, strawberries, raspberries, blackberries, dewberries, nuts, and citrus fruits.

In comparative tests of northern with home-grown seeds, the seeds grown upon the grounds of the stations gave equally good or better

results in the case of cucumbers, cantaloupes, lettuce, peppers, Irish potatoes, pumpkins, radishes, and tomatoes. The results in many of the other crops are not indicated. Tabulated data are given on fertilizer tests with cabbages, cantaloupes, eggplants, watermelons, Irish potatoes, sweet potatoes, and tomatoes, and an experiment in growing cucumbers under glass is described. The comparative ability of the crops to endure the drought is reported. Mention is made of the striped cucumber beetle (*Diabrotica vittata*) and the 12-spotted beetle (*Diabrotica 12-punctata*), and a mixture of 12 qt. of air-slaked lime and 1 pt. of coal oil applied with a hand bellows or powder gun is recommended for keeping them in check.

Winter forcing of asparagus in the open field, J. C. WHITTEN (*Missouri Sta. Bul. 43, pp. 54-62, figs. 2*).—Various methods of forcing asparagus are noted and a method of forcing a crop in the field is described. Forcing asparagus in the field has two advantages over removing the roots to a forcing house. It avoids the trouble and expense of transplanting them and it saves the plants from being ruined by the forcing process, as in the case of plants removed to forcing houses. The method used at the station is as follows: Trenches are made between the rows by running a double furrow, throwing the soil in the rows of plants, and then making the trenches uniform with a spade. When finished they are 3 or 4 in. lower than the crowns of the plants. They are then covered with 12-in. boards resting on 4-in. blocks on either side of the trenches, thus forming tunnels between the rows. The boards are covered with 2 or 3 in. of soil and then the whole bed is covered with 5 or 6 in. of horse manure. Steam is carried from the boiler to the central tunnel by a steam pipe and from there forced into the tunnels through steam hose. The steam penetrates the soil of the beds, warming it to the desired temperature.

This method was tested at the station in the winter of 1896. The field used had been planted to asparagus some 10 years previous to the experiment. Six rows 4 ft. apart and 50 ft. long were prepared for forcing. Steam was first applied November 14. It was discharged in each tunnel for not over 5 minutes at a time, about 1 hour being required to heat the bed to a temperature of 60° F. After the first day the bed was steamed on an average of twice in 3 days, and only for 5 minutes for each tunnel. The first asparagus was cut 10 days after steaming was begun. It was as large as that ordinarily produced in spring and much more crisp. Cuttings were made almost daily for a month, when the growth became weak. The second test was begun December 16 and carried out as in the first test. The bed prepared for forcing was 25 by 75 ft. The first cutting was made 2 weeks after the first steaming. The time of cutting was more irregular than in the first test, and was prolonged about 2 months. The weather being colder, somewhat more steam was required than in the first test. The plants forced were allowed to grow without cutting during the summer of 1897, and the spring growth of

1898 showed that one season's growth after forcing was sufficient for the plants to regain their normal vigor. In the winter of 1897-98 a test was made with a bed 25 ft. square, to determine the amount of coal necessary to force a given area of asparagus and the value of the product. The steam was first used December 29, the first asparagus was cut January 12, and cutting was continued until February 25. Steam was forced into the tunnels a total of 60½ hours; 2,308 lbs. of coal, valued at \$1.82, were used in heating the bed. The yield was 162 bunches (80 lbs.), valued at from 10 to 20 cts. per bunch.

It was found that about 5 minutes at a time was as long as steam could be forced into a tunnel without danger of overheating the asparagus. In regard to the advantage of allowing the steam to come in direct contact with the soil, the author says:

"The steam, coming in direct contact with the soil, readily penetrates it, heating the whole bed uniformly; whereas if the tunnels are heated by inclosed steam or hot-water pipes, the soil becomes too hot and dry close to the tunnels, while it is too cold midway between them. Forcing steam into the tunnels keeps the soil moist and maintains more continuous fermentation of the manure mulch, thus promoting steady heat."

The bulletin concludes with general remarks and suggestions on the culture of asparagus in Missouri.

Improvement of the wild carrot by grafting it on the cultivated carrot, L. DANIEL (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 2, pp. 133-135).—The author reports the results of grafting the wild carrot upon a well-known variety of cultivated carrot having red roots. The stock exerted an influence not only upon the scion itself, but also upon the seedlings of the scion. The seedlings presented anomalies in the number and form of the cotyledons, the young plants from the grafted wild carrot were larger, greener, and less villous than those from the ungrafted wild carrot—i. e., in general intermediate between the wild and cultivated carrot. As the plants became older some of them followed the spreading habit of the wild carrot and others the erect habit of the cultivated carrot. The roots were white, like those of the wild carrot, but with a diameter from 2 to 3 times that of the latter and from one-fourth to one-third that of the cultivated carrot. Out of 30 plants from the grafted carrot 8 ran to seed the first season, an occurrence which, though fairly common in the cultivated carrot, is very rare in the wild carrot. The author believes that these results demonstrate the possibility of improving wild plants by grafting, followed by an intelligent selection of the offspring of the scion.

The fruit industry and substitution of domestic for foreign-grown fruits, W. A. TAYLOR (*U. S. Dept. Agr. Yearbook 1897*, pp. 305-344, pls. 5).—This article treats of the history of the development of the fruit industry in the United States and of the importation and exportation of fruits, and notes briefly the possibility of substitution of domestic for foreign-grown fruits. Numerous tables are given showing

the statistics of imports of fruits and fruit products by decades from 1830 to 1890 and by years from 1891 to 1897. Imports of many classes of fruits have decreased noticeably in the last few years, owing to the increased home production of these fruits and of others which have been substituted for them. Exports of such fruits as are exported, notably the apple, has steadily increased. Exports of canned and dried fruits of various kinds are becoming very important. In 1897 the total exports of fruits, fruit products, and nuts were valued at \$7,828,572, as against similar imports to the value of \$20,962,782.

A report on damage to fruit trees caused by the severe freeze of November 26-28, 1896, J. A. BALMER (*Washington Sta. Bul.* 30, pp. 20).—In a preliminary note the use of the nomenclature recommended and adopted by the American Pomological Society is urged. During the summer of 1897 the author visited the fruit-growing regions in the Wallawalla, Yakima, and Snake River valleys, and a large number of orchards in the Palouse country and in western Washington, and has reported in this bulletin the information gathered here concerning the damage done to fruit trees by the unusual cold period of the previous November. Several peculiar effects of the cold were brought out by the study. Of trees under apparently the same conditions one may have been severely affected while another of the same variety 25 ft. distant escaped uninjured. The trunks of some Agen prune trees were burst wide open, while others near by were left apparently in good order. Certain branches of a tree would be entirely killed while others were scarcely damaged. Detailed reports of 13 orchards in the Wallawalla Valley, 13 in the Yakima Valley, and 3 in the Palouse country including that of the station are given, also tables showing the percentage of dead and damaged trees in the Wallawalla and Yakima valleys. The conclusions reached are summarized in substance as follows:

“On low damp ground the damage to trees was very great, while trees of the same age and variety on drier grounds came through uninjured. Trees with high exposed trunks, especially those leaning from the afternoon sun or from the southwest, were greatly damaged in trunk, while in many cases the limbs and young growth were not affected. Agen prune is tenderer than Italian, Golden Drop, or Pond. Napoleon cherry is one of the tenderest varieties grown in the State. It suffered everywhere in the eastern part of the State, except possibly in the Snake River Valley. Of the popular varieties of apples, Yellow Newtown, Esopus, Yellow Bellflower, and Fall Pippin proved most tender. The hardier varieties are Ben Davis, Blue Pearmain, Jefferis, Fameuse, Twenty Ounce, Red June, Red Astrachan, Gloria Mundi, Missouri, Yellow Transparent, Limber Twig, and Waxen. Seedling peaches proved much harder than budded trees. Amsden, Elberta, and Foster proved as hardy as any in their class. Alexander proved very tender. The damage was greatest where the land was lowest and where the cold air was held in pockets. In most instances late summer irrigation proved injurious, causing the trees to grow too late in the fall, leaving them in a very tender condition to go into winter quarters. Late cultivation has a similar effect on fruit trees as has late irrigation. It is not safe to cultivate much later than the middle of July. Where orchards were weedy and little cared for, the damage by frost was light; this, however, is no plea for weeds, but goes to show that if trees are encouraged to mature their wood early in the fall they will be

in better condition to endure the rigors of winter. While the author is firmly of the opinion that fall and winter irrigation is absolutely necessary, yet it seems to him to be a mistake to keep up irrigation or even cultivation during the weeks in the fall when trees naturally mature their wood; better to have a few weeds than to have a lot of immature wood and late growth. After the leaves are well down and growth has ceased is a good time to apply water; this is nature's way."

Lawns and lawn making, F. LAMSON-Scribner (*U. S. Dept. Agr. Yearbook 1897*, pp. 355-372, pls. 7).—The article gives suggestions for the establishment and care of lawns, based upon replies to a circular of inquiry addressed to superintendents of parks in various parts of the United States and upon the experience of the author. A number of replies to the circular are quoted. In regard to the selection of lawn grasses the author says:

"The varieties suited to temperate climates, not subject to excessive drought or where water may be employed, are Kentucky blue grass, Rhode Island bent, and creeping bent. For shaded streets and parks, hard fescue and various leafed fescue, especially the latter, may be used to advantage, and in northern latitudes woodland meadow grass is a desirable variety for shaded situations. In the warmer portions of the South, Bermuda and the variety known as St. Lucie grass stand first, and when the soil is somewhat moist or very sandy St. Augustine grass may be substituted. Curly mesquite is recommended for trial in the warmer regions of the Southwest too dry for the successful cultivation of Bermuda."

The turf formed by various grasses is illustrated from photographs. Thorough preparation and constant care are considered essential to success with lawns. By way of summary the author says:

"A perfect lawn consists of the growth of a single variety of grass, with a smooth even surface, uniform color, and an elastic turf which has become, through constant care, so fine and so close in texture as to exclude weeds, which, appearing, should be at once removed. Briefly, such a lawn may be secured by thorough preparation of the soil and the application of suitable fertilizers; by seeding with pure seed of the highest quality; by proper attention to irrigation and the maintenance of fertility; by the prompt removal of weeds, and, finally, by the frequent and intelligent use of the roller and lawn mower."

Cultivation of the sweet potato, J. A. Frye (*Jour. Jamaica Agr. Soc.*, 2 (1898), No. 11, pp. 475, 476).—Popular notes.

Some edible and poisonous fungi, W. G. Farlow (*U. S. Dept. Agr. Yearbook, 1897*, pp. 453-470, pls. 10).—The paper gives in a popular way the characteristics of a few of the most common edible and poisonous fungi. The forms considered are *Agaricus campestris*, *A. arvensis*, *Amanita phalloides*, *Hypholoma appendiculatum*, *Coprinus comatus*, *C. atramentarius*, *C. micaceous*, *Lepiota procera*, *Cantharellus cibarius*, *Marasmius oreades*, *Lactarius deliciosus*, *Pleurotus ostreatus*, *Boletus subtentus*, *Fistulina hepatica*, *Hydnum imbricatum*, *H. repandum*, *Morchella esculenta*, *Lycoperdon giganteum*, *L. cyathiforme*, and *Scleroderma vulgare*. These are illustrated by plates. A number of rules are given to aid the collector in determining edible fungi.

Some edible and poisonous fungi, W. G. Farlow (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 15*, pp. 453-470, pls. 10).—This is a reprint from the Yearbook of this Department for 1897 (see above).

Edible agarics, M. R. (*Jour. Hyg.*, 23 (1898), No. 1141, pp. 361-363).—A general description of the cultivation of mushrooms in Paris, condensed from an article in *Science Française*.

Cherry culture, G. H. Powell (*Delaware Sta. Rpt. 1897*, pp. 175-197, figs. 9).—A reprint of Bulletin 35 of the station (E. S. R., 9, p. 834).

Strawberries, F. S. EARLE (*Alabama College Sta. Bul.* 24, pp. 139-154).—A popular bulletin on growing and marketing strawberries. "In the opinion of the writer the strawberry acreage of the State could be largely increased with profit, and with less chance of loss than with most other horticultural crops." Directions are given for the selection of soils, use of fertilizers, preparation of soil, planting, cultivation, and mulching. Insects and diseases affecting strawberries are briefly considered, and notes are given on picking, packing, and shipping the fruit. From tests of 35 varieties grown for 2 seasons under rather unfavorable conditions, the author thinks the following can safely be recommended for general planting in all parts of Alabama: Michel, Lady Thompson, Brandywine, and Glenn Mary. Gardner and Meeks produced the most vigorous vines and hardest foliage.

Pruning, O. E. ORPET (*Amer. Gard.*, 19 (1898), No. 193, p. 619).—The gist of the article is given in the author's summary, as follows: "Summer pruning tends to direct the vigor of the trees into legitimate channels making spring pruning a very small matter when the former has been followed up from the time of planting the trees. Spring pruning is necessary when the trees have been neglected for a time. It will not check vigorous growth, rather increase it indeed, but in summer see that this vigor is so placed as to form good fruit bud bearing wood by summer pinching of the strongest growths. . . . All flowering shrubs should be pruned after flowering; then a good display is secured, and the efforts of the shrub are directed toward making wood to flower next season."

The fruit industry and substitution of domestic for foreign-grown fruits, W. A. TAYLOR (*U. S. Dept. Agr., Division of Pomology Bul.* 7, pp. 305-362, pls. 5).—This is a reprint from the Yearbook of this Department for 1897 (see p. 549), with the addition of a discussion of fruit exports and notes on 10 varieties of apples suitable for the export trade as follows: Baldwin, Ben Davis, Jonathan, Northern Spy, Rhode Island, Roxbury, Tompkins King, Winesap, Yellow Newton, and York Imperial.

The reciprocal action of scion and stock (*Gard. Chron.*, 3, ser., 24 (1898), No. 616, p. 288).—A brief review of Daniel's work with carrots (see p. 549) is given, with a note on the physiology of the interaction of stock and scion.

The effect of stock on scion, and vice versa (*Wiener Illus. Gart. Ztg.*, 23 (1898), Nos. 8-9, pp. 299, 300).—A brief review of Daniel's work (*E. S. R.*, 5, p. 1089; 9, p. 945; 10, p. 549).

The effect of the graft on the flavor of the fruit (*Gard. Chron.*, 3, ser., 24 (1898), No. 614, p. 246).—Notes on the work of Daniel and other authorities (see p. 549).

The principles and practice of bulb growing, W. C. WORSDELL (*Gard. Chron.*, 3, ser., 24 (1898), No. 624, p. 422).—One of a series of articles on this subject.

Bulb growing in America, W. F. MASSEY (*Amer. Florist*, 14 (1898), No. 544, p. 400).—The successful growing of bulbs of Dutch and Roman hyacinths, narcissi, and *Lilium candidum* in North Carolina is reported. The author believes that with experience Bermuda lily bulbs can also be grown successfully.

Italian cannas in 1898, E. ANDRÉ (*Rev. Hort.*, 70 (1898), No. 21, pp. 497-500, fig. 1).—Notes on new Italian cannas.

Cannas in 1898, J. S. WILSON (*Amer. Florist*, 14 (1898), No. 551, pp. 625-628, fig. 1).—Brief notes on a considerable number of varieties of cannas grown at Western Springs, Illinois, in 1898.

The cyclamen, W. W. GORDON (*Amer. Gard.*, 19 (1898), No. 203, pp. 773, 774, fig. 1).—The article gives a method of culture by which cyclamens are carried over two years instead of being allowed a resting period at the end of one year's growth.

Economic use of bamboos, A. B. FREEMAN-METFORD (*Gard. Chron.*, 3, ser., 24 (1898), No. 605, p. 92).—A brief synopsis is given of a lecture delivered by the author before the Royal Horticultural Society at its meeting July 19, 1898.

The shrubby St. John's worts, W. J. BEAN (*Garden*, 54 (1898), No. 1413, pp. 490-492, figs. 3, pl. 1).—Notes upon the adaptability of the genus *Hypericum* for garden planting, together with descriptive and cultural notes on certain species.

How to make a lawn, H. A. SURFACE (*Amer. Gard.*, 19 (1898), No. 205, pp. 805, 806).—Directions are given for making and caring for lawns. To sow an acre the author recommends a mixture as follows: June grass 10 lbs., redtop 10 lbs., perennial rye grass 10 lbs., rough meadow grass 5 lbs., timothy 5 lbs., sweet vernal grass 5 lbs., and white clover 5 lbs.

Notes on watering, F. CRANFIELD (*Amer. Florist*, 14 (1898), No. 545, pp. 434, 435, fig. 1).—The article gives a few notes on the use of warm and cold water for both greenhouse and outdoor plants, the notes being supplemental to those given in a previous issue (E. S. R., 9, p. 1053).

SEEDS—WEEDS.

Wind distribution of seeds, E. M. HUSSONG (*Proc. Nebraska Acad. Sci.* 1896, pp. 253-257).—Under the author's direction experiments were carried on for 4 years to ascertain the effect of wind as a distributing agent of weed seeds. In order to secure the data desired, deep tin cans were anchored in a number of different exposures in such a way as to collect seeds and other debris carried by the air. The collection made in September for 4 years is tabulated, which shows the following percentages:

Weed seeds distributed by winds.

Orders.	Per cent.	Orders.	Per cent.
Portulacaceæ.....	14.6	Cyperaceæ.....	4.2
Compositæ.....	12.7	Onagraceæ.....	4.1
Amarantaceæ.....	12.3	Crucifereæ.....	3.8
Chenopodiaceæ.....	9.8	Leguminosæ.....	3.7
Plantaginaceæ.....	7.5	Polygonaceæ.....	2.5
Asclepiadaceæ.....	7.2	Convolvulaceæ.....	1.5
Gramineæ.....	6.7	Unknown.....	4.1
Solanaceæ.....	4.5		

It appears that of these seeds 16.1 per cent were distributed by breezes, 17.8 per cent by local winds, 36.3 per cent by high winds, and 26.6 per cent by continued gales. Naturally the ones distributed by the lighter winds were those which were provided with pappus or some other special arrangement for distribution, while the heavier seeds are scattered only by the high and continuous winds.

In October 20 per cent more Compositæ, 8 per cent more of milk-weeds, and from 1 to 3 per cent more grasses, amaranths, and chenopods were collected. In November the collections were notable for a very great increase in the percentages of amaranths and chenopods. During December, January, February, and March, on account of the ground being covered with snow or frozen, but slight movements of seeds were observed. In April the spring winds produced quite a marked effect on the distribution, and at this time seeds of the common purslane, tansy mustard, black mustard, wild pea, and winged dock were very abundant in their distribution.

These experiments only show data relative to the horizontal distribution of seeds, it being generally believed that the distribution of weed

seeds takes place within the stratum of air that lies about 30 or 40 ft. from the earth's surface. The desirability of investigations as to vertical distribution is pointed out.

An investigation of various germination media, B. JONSSON (*Report Lund Seed-Control Station for 1897*, pp. 7-12, 28, 29).—The general practice adopted in Scandinavian seed-control stations is to germinate the seed between pieces of moist paper or cloth. The medium in which the seed is placed differs greatly among the Swedish stations. The author collected over 30 different kinds of paper or cloth used for this purpose in Swedish stations, and subjected them to a critical examination. A number of samples were tested to study which kinds were especially adapted for the purpose in view, and determinations made of weight, ash content, porosity, hygroscopicity, and rapidity of evaporation from the surface of the paper or cloth. The samples examined were grouped as filter paper, blotting paper, brown paper, felt, moleskin, and linen. The following table shows the average data obtained for these groups of media:

Examination of germination media.

Medium.	Number of samples.	Weight of 19.76 sq. cm.		Ash content.	Height to which water rose, during 3 min.	Amount of moisture taken up in saturated atmosphere during 24 hours.		Evaporation during 4 hours—	
		Grams.	Per cent.			mm.	Per cent.	Grams.	Per cent.
Filter paper (white).....	11	0.17	0.46		2.90	25.5	2.695	69.0	
Blotting paper (white or colored).....	12	.37	a. 47		31.0	16.0	1.806	62.0	
Brown paper.....	9	.25	2.06		13.0	24.0	1.777	58.5	
Felt.....	2	.70		3.5	19.5	.483	9.0	
Moleskin.....	1	1.02	.10		68.0	11.9	.315	11.0	
Linen.....	1		21.0	62.5	

a Average for 6 samples.

In order to be adapted for use in germination tests, the paper should be pure, free from injurious components or coloring matter, and as far as possible free from fungi and bacteria. It should therefore be kept and handled carefully, and preferably sterilized. It should be soft and pliable and of good keeping quality. Its ash content should be as low as possible, since a high ash makes the paper hard, and may interfere with the germination by the ash components being dissolved in the water of the germination bed. Porosity is essential, to permit of circulation of air; for this reason heavily sized paper is objectionable. In the author's opinion a paper fulfilling the preceding demands is preferable to either clay or terra-cotta dishes, sand, or soil beds.—F. W. WOLL.

Report of Swedish seed-control stations for 1896 (*Meddel. K. Landtbr. Styr., 1897, No. 42, pp. 314-382*).—The report includes the average data, with extremes, of 9,913 seed analyses made at the 18 Swedish

State seed-control stations, of which 3,588 analyses were made for farmers, 5,548 for seedsmen, and 777 in investigational work conducted by the stations. Of the analyses made, 25.1 per cent were made at the Lund Station, 12.9 per cent at Stockholm Station, 11.7 per cent at Örebro Station, and the rest divided among the remaining 15 seed-control stations.

While the quality of most kinds of seed examined was very good, considerable variations were found, as shown below:

Variations in percentage of pure viable seed.

Kind of seed.	Number of samples.	Pure viable seed.		
		Average.	Maximum.	Minimum.
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Winter rye	308	90.1	99.7	18.8
Two-rowed barley	296	95.8	99.9	14.7
Six-rowed barley	200	96.1	100	13
White oats	414	91.7	100	8
Red clover	1,296	88.1	98.7	1.4
Kidney vetch	29	87.5	98.8	5.8
Timothy	615	86.1	99.2	36.2
Swedish turnip	100	95.5	99.9	27.5
Carrot	59	60.9	92.5	18.8
Parsnip	10	53	87.1	1
Fir (<i>Abies excelsa</i>)	76	80.1	98.9	10.7
Norway pine (<i>Pinus sylvestris</i>)	78	83.8	97.9	9.7

Determinations of the viability of weed seeds made at the Jönköping Station showed the following results: *Centaurea cyanus* 88.3 per cent, *Anthemis tinctoria* 57.5 per cent, *Cerastium vulgatum* 89 per cent, *Cuscuta trifolii* 19.5 per cent, *Bromus secalinus* 94.3 per cent, *Pruella vulgaris* 67.8 per cent, *Stellaria media* 72 per cent, and *Cirsium arvense* 1.5 per cent.—F. W. WOLL.

Additional notes on seed testing, G. H. HICKS and S. KEY (*U. S. Dept. Agr. Yearbook 1897*, pp. 441-452, figs. 3).—In continuation of previous papers published in the Yearbooks of this Department on pure-seed investigation, the authors in the present paper treat mainly of the special apparatus, methods, and expedients which have been adopted in the regular work of the Seed Laboratory of this Department. Attention is also called to the importance of field tests, which are too frequently neglected in ordinary seed-testing work.

Some methods in the study of mature seed, L. H. PAMMEL (*Jour. Appl. Micros.*, 1 (1898), No. 3, pp. 37-39, figs. 6).

The choice of seed, G. BATTANCHON (*Prog. Agr. et Vit.*, 30 (1898), No. 44, pp. 527-531).—The author in a semipopular article points out the value of good seed and the necessity for their selection.

On the selection of seed by their specific weight, L. DEGRULLY (*Prog. Agr. et Vit.*, 30 (1898), No. 42, pp. 453-455).—The author states the general advantage accruing from the use of heavy seed and cites examples in which there was an increased yield of oats of 260 kg. grain and 360 kg. straw per hectare from the heavier seed. In the case of maize a gain of 33½ per cent was due to the use of heavy seed. Report of the seed-control station at Lund (Sweden) for 1897, B. Jonsson (Malmö, 1898, pp. 29).

Dodder, R. HELMS (*Producers' Gaz. and Settlers' Rec. [West. Australia]*, 5 (1898), No. 5, pp. 394-396, fig. 1).—Notes are given on *Cuscuta trifolii*, which is parasitic on alfalfa. Spraying infested plants with a solution of iron sulphate (1 lb. dissolved in 10 gal. water), burning, mowing, and covering the affected plants several inches thick with stable manure, and thus thoroughly smothering the weed, are among the methods suggested for its eradication.

Upon the destruction of Equisetums (*Ztschr. Pflanzenkrankh.*, 8 (1898), No. 3, pp. 175-178).—Notes are given on the occurrence of *Equisetum patustre*, with suggestions for its eradication.

Two phanerogamous parasites of red clover, B. D. HALSTED (*Bul. Torrey Bot. Club*, 25 (1898), No. 7, pp. 395-397, fig. 1).—Notes are given on the parasitism of *Cuscuta epithymum* and *Orobanche minor* on red clover.

Orobanche speciosa, G. HENSLOW (*Gard. Chron.*, 3. ser., 24 (1898), No. 607, p. 89).—The author reports having observed a field of beans just outside of Cairo, Egypt, which was seriously attacked by this parasitic plant.

Weeds which afford protection to noxious insects, A. M. LEA (*Producers' Gaz. and Settlers' Rec. [W. Australia]*, 5 (1898), No. 4, pp. 286, 287).—The author enumerates a number of weeds which serve as food plants for noxious insects and suggests a destruction of these weeds wherever abundant.

Noxious weeds, R. HELMS (*West Australian Settler's Guide and Farmer's Handbook*, 1897, pt. 3, pp. 532-563, figs. 14).—Descriptive notes are given of 68 of the more troublesome weeds, with suggestions for their eradication.

DISEASES OF PLANTS.

Peach yellows in nursery stock, G. H. POWELL (*Delaware Sta. Rpt.* 1897, pp. 168-174, figs. 5).—The author states that while inspecting nurseries in October, 1896, it was noticed that small, yellowish, willow-like shoots occurred from the buds of a considerable portion of the trees budded during the season. The general appearance of these indicated that the nursery stock was attacked by peach yellows and specimens submitted to the Division of Vegetable Physiology and Pathology of this Department confirmed the supposition. The author, however, became convinced that the general appearance was not due to peach yellows, but that its origin was to be found in the constriction caused by the inserted bud, the hot, dry weather during the budding season, and the subsequent warm rains in September, which caused a secondary growth of the wood. In four nurseries budded late in the summer and fall 32, 34, 49, and 86 per cent of the trees presented the sprouted appearance. In the nursery where 86 per cent showed this growth two buddings had been performed, as the hot, dry weather seriously interfered with the first budding. Investigations made to determine the influence of crowding, air, light, and root-foraging extent seem to indicate that the outside rows, which were subjected to greater drought on account of lack of shade, suffered the most.

When a comparison of the willow shoots from the nursery trees was made during the month of October with those of similar size from trees known to be affected with peach yellows, several striking differences were observed. The shoots from trees with yellows were more slender, paler in color, with drooping leaves, and they had continued growing at

the tip until checked by frost, while those from the nursery stock were upright and green with a true but undeveloped terminal bud. The suspected trees were allowed to grow during the spring of 1897 and watched closely during the summer months, and in no case did any sign of yellows appear.

“The origin of the yellows-like shoots on the bodies of nursery trees that were budded in 1896 is clearly ascribed, primarily, to the partial girdle formed by the inserted bud and then to the subsequent climatic conditions which pushed forth a fall growth from the dormant buds around the constriction. Buds that start early in the season grow rapidly into normal, healthy shoots, but the growing activity of the tree is greatly reduced in the fall, and the buds starting at that time develop slowly and form shoots with short nodes and small, undeveloped, light-colored leaves. These small shoots, in all probability, would have grown into strong, healthy branches had they begun their development in the summer months.

“It should be said that a similar condition prevails in recently budded nursery stock, to a greater or less extent, every fall, and whenever the climatic conditions are such as to induce a fall growth in fruit trees the shoots on recently budded nursery stock will be more abundantly developed. The same phenomena may be seen in pear, plum, and apple stocks, and it is more marked in those varieties which naturally have a tendency to sucker. It can be induced by checking the growth in rapidly growing trees in a variety of ways, such as by budding, grafting, pruning, girdling, bending a branch, or by tying a string around it.”

An outline plan is given of the experiments which were conducted with a view of preventing tomato diseases, but the results were so inconclusive that they are not published.

A preliminary report upon the diseases of the peach; experiments in spraying peach trees, A. D. SELBY (*Ohio Sta. Bul.* 92, pp. 179-268, pls. 12, figs. 12).—*Diseases of the peach* (pp. 179-236).—After briefly discussing the peach industry in Ohio, the author gives a report on the diseases to which the peach is subject, dividing them under the following 5 heads: Those due to mechanical agencies or unfavorable soil conditions; injury due to atmospheric conditions; diseases referred to unknown or doubtful causes; fungus diseases of the peach, and those caused by animal organisms and insects.

Among the disease due to mechanical and soil conditions, the author mentions wounds, resulting in exudation of gum, and diseased conditions caused by underdrained soil.

The injuries due to atmospheric conditions mentioned are freezing and wind storms, hail, etc.

Of the diseases referred to unknown or doubtful causes, the author mentions peach yellows, peach rosette, a twig disease accompanied with gum flow, dropsical swellings of twigs and branches, twig spots, and crown gall.

Suggestions are given for the prevention of these various diseases. Among the means for the prevention of the yellows the author recommends the destruction of all affected trees and care that tools used in digging up and destroying the diseased trees should be thoroughly sterilized so as not to communicate the disease to others. The peach

rosette, while briefly described, has so far not been demonstrated to exist in Ohio. The twig disease described, which is accompanied by an exudation of gum, affects the twigs, branches, and even the trunks of the trees. There are no evidences of previous perforations of the bark as when attacked by some bark beetle. A sectional examination of diseased branches shows a dead or injured area. The author enumerates various hypotheses as to the possible cause of this disease, but does not believe that the true cause is known. He believes, however, that some impairment of vigor or interference of normal life activities is a partial, if not complete, explanation of the cause. The disease is of a progressive nature and ultimately destroys the trees, and on this account infected ones should be quickly destroyed.

Dropsical swellings of the twigs and branches and twig spots are briefly described. No fungus or other organism has so far been found which is the probable cause of these affections. The nature and cause of crown gall does not admit of precise statements. The growth of the galls are usually soft, corky, or spongy upon the various parts of the tree. Below ground they are renewed on the peach each season, the old galls falling away and decaying, while the new ones are formed. By many authors the chief cause of these galls has been attributed to nematodes, but the author thinks this hypothesis is hardly warranted by the facts as observed. Experiments with lime, sulphur, and wood ashes have failed to cure any trees affected by crown gall, and the author suggests that any tree showing rough gall growths should be thrown out and burned.

Among the fungus diseases of the peach described are the peach rot, peach scab, brown or pustular spot, anthracnose, peach mildew, leaf curl, leaf spots, a constriction disease of the stem and branch, which is said to be due to *Phoma persica*, twig blight, twig spots, and a root rot. These diseases are more or less briefly characterized and so far as known remedies are suggested.

The diseases due to animal organisms, as nematodes, root borers, and root lice are briefly described.

Experiments in spraying peach trees (pp. 237-260).—The author reports a series of experiments which have been carried on for 3 years in the commercial spraying of peach orchards. These experiments are said to have fully demonstrated the practicability of spraying peach trees with Bordeaux mixture for the prevention of leaf curl, scab, and pustular spot diseases. In spraying for the prevention of leaf curl the application seemed to have a cumulative effect. The disease on trees sprayed in 1897 which had been sprayed the two previous seasons amounted only to 8 per cent.

Three applications of the fungicide reduced the amount of spotted peaches to 1 per cent, and 2 sprayings reduced the pustular spot disease to $2\frac{1}{2}$ per cent, while unsprayed trees bore 16 per cent of affected peaches. For the early spraying of trees the author recommends a

strength of solution double that which the trees would stand during the later period of the season. The cost of spraying peach trees, when conducted on as large a scale as these experiments, amounted to 1½ cts. per tree for each application. The author states that four applications can be made on fairly level orchards for less than 6 cts. per tree, this estimate covering the cost of both labor and spray materials.

Smuts and rusts of grain in Idaho and the most approved methods of dealing with them, L. F. HENDERSON (*Idaho Sta. Bul.* 11, pp. 31, figs. 15).—The author has given descriptive notes, largely compiled, of the stinking and loose smut of wheat, loose smut of oats and barley, and corn smuts, together with notes on the rusts of various cereals. For the prevention of the smut of wheat, in 1895 and 1896 experiments were conducted with different strengths of copper sulphate and the hot-water treatment. Deductions are drawn from the experiments of the first year, no record having been kept of the yield of grain and straw in the second year's tests. The plats seeded with untreated grain averaged about 86 per cent smutted grain, while those treated with different strengths of copper sulphate and those given the hot-water treatment showed that both methods were very effective in suppressing the stinking smut of wheat.

After a general discussion of the rusts of cereals the author suggests the fallowing of wheat fields as a possible method of keeping down the attacks, the fallow lands being closely pastured before plowing. Where one crop of cereals follows another the stubble and all infected straw should be burned. While all varieties of wheat seem to suffer from rusts the early ripening varieties are least affected, and those varieties with straight stiff leaves are less affected than those having weaker foliage. It is thought that the red wheats are less affected than the white varieties, notably the Velvet Chaff, which is extremely subject to attack. Poor drainage and an excess of nitrogen in the soil seems to aggravate the disease.

Concerning the red rust of the currant, J. ERIKSSON (*K. Landt. Akad. Handl. Tidskr.* 37 (1898), No. 3, pp. 194-201, pl. 1).—The author studied the rust (*Puccinia ribis*) found on the fruit and foliage of red currants. The investigations disclosed the fact that this rust is a true micropuccinia, producing only teliospores, which do not become viable until the spring after they have been formed. A so-called specialization is found also in case of this rust, which attacks red and white currants (*Ribes rubrum*), but not black currants (*R. nigrum*) or gooseberries (*R. grossularia*). The disease reappears in the spring through infection from wintered spores, after an incubation period of 29 to 39 days.

The precautions to be observed in case of an appearance of this disease are given as follows: In the fall, carefully gather, remove, and burn leaves and berries which from time to time fall from diseased bushes; in the spring, when the currant bushes are about to leaf, one

or more thorough sprayings with Bordeaux mixture are made, not only on the bushes, but on the ground under and around them.—F. W. WOLL.

The effect of benzolin and sulfurin on potato plants, R. THIELE (*Ztschr. Pflanzenkrank.*, 8 (1898), No. 3, pp. 143-146).—On account of the reputed fungicidal value of these insecticides the author investigated, in the summer of 1897, the effect of spraying benzolin and sulfurin on potato plants for the prevention of the potato blights. Fruit trees and *Vicia faba* were likewise sprayed.

Fifty varieties of potatoes were sprayed with these substances and it was found that the effect on the different varieties varied considerably, some plants being seriously injured, the leaves being more or less destroyed and the plants reduced in size, while others were of normal growth. Comparing the results as tabulated, it appears that while the amount of disease was somewhat reduced by the use of the fungicides, there was little difference in the action of the two, and in general the tubers from the treated plats were smaller than those from the checks.

Danger of introducing a Central American coffee disease into Hawaii, W. T. SWINGLE (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Circ. 16, pp. 4*).—The author calls attention to the presence of a very serious coffee disease in Central America, which is due to the fungus *Stilbum flavidum*. This disease attacks the plant, producing round or oval dingy yellowish gray spots on the branches, fruits, and especially on the foliage. The necessity for the inspection of all importations of plants from infested regions is pointed out.

Notes are also given on the coffee-leaf disease due to *Hemileia vastatrix*, which has about completely destroyed the coffee plantations of Ceylon, and also a disease due to nematodes, which is known in Brazil.

Phytopathological notes, F. SITENSKY (*Abs. in Ztschr. Pflanzenkrank.*, 8 (1898), No. 3, pp. 148, 149).—The author gives notes on the abnormal growth and condition of a number of plants, some of the most striking of which are herewith mentioned.

The effect of lightning on an alfalfa field is shown, in which a field in full bloom showed the day after having been struck with lightning a circle about 5 meters in diameter, where the plants were completely wilted. The effect on a pear tree, a poplar, and a larch is also given.

The occurrence of potato tubers in the axils of the leaves above ground is mentioned; wherever abundant there were no tubers found below ground.

Especial mention is given of abnormally swollen sugar and fodder beets which were found in a field the soil of which was unusually dry. The sugar content of the beets was in every case much lower than that of the mother beets.

Infection experiments were conducted with *Plasmodiophora brassicae*, in which various species of Brassica, as well as *Cheiranthus cheiri*, *Raphanus sativus*, *Eruca sativa*, and *Erysimum crepidifolium* were successfully inoculated. The use of lime in the soil was found a good means for the prevention of this disease.

The appearance of a bacterial disease of beets is mentioned, and also experiments for the inoculation of potato blights.

Some notes are given on the occurrence of various smuts and rusts on cereals, and it is stated that spores of *Ustilago maydis*, *U. cruenta*, *U. crameri*, *Tilletia caries*, and *T. lavis* retained their power to germinate for, at the most, two or three years.

Fungi on the wheat plant, D. McALPINE (*Agr. Gaz. New South Wales*, 9 (1898), No. 9, pp. 1009-1015, pl. 1).—Notes several species, some of which are new to science.

Notes on the variation of the teleutospores of Puccinia windsoriæ, J. A. WARREN (*Amer. Nat.*, 32 (1898), No. 382, pp. 779-781, pl. 1).—The author reports collecting this fungus on *Muhlenbergia racemosa*, and examinations of the material showed the teleutospores as having 1 to 4 cells instead of the normal 2 cells. Other variations are noted.

Cracking of pears and apples (*Gard. Chron.*, 3. ser., 14 (1898), No. 619, p. 641, figs. 3).—Descriptive notes are given of the injury due to *Fusicladium dendriticum*, and 2 or 3 applications of Bordeaux mixture are recommended as a preventive treatment.

Potato scab, W. G. SMITH (*Gard. Chron.*, 3. ser., 24 (1898), No. 621, p. 372).—In a paper read before the Royal Horticultural Society the author described the potato scab and commented upon the various assigned causes and the use of corrosive sublimate, sulphur, and kainit as preventive measures.

The gooseberry fungus, H. T. SOPPITT (*Gard. Chron.*, 3. ser., 24 (1898), No. 608, p. 145, fig. 1).—The author describes *Ecidium grossulariæ* and mentions the discovery of Klebahn, that the uredospore and teliospore forms occur on *Carex acuta* and *C. goodenorii*, the fungus being designated as *Puccinia pringsheimiana*. The author reports experiments in which the spores were transferred from the gooseberry to various species of *Carex* and, while no results were obtained on either *Carex hirta* or *C. leporina*, the infected plants of *C. goodenorii* produced a promising crop of teliospores.

A peony disease, G. MASSEE (*Gard. Chron.*, 3. ser., 24 (1898), No. 607, pp. 124, 125, fig. 1).—The author describes a disease caused by *Botrytis* sp., and as preventive measures recommends the following:

“Remove and burn all drooping stems the moment the first symptoms are observed. Where the disease has previously existed, or better, under any circumstances, remove the surface soil early in spring, and replace with fresh soil mixed with quicklime. Do not use green manure as a top-dressing. The mycelium of the fungus is not perennial in the root of the peony, so that it starts life perfectly free from its enemy each year, and can only become diseased through inoculation from sclerotia lying in the soil, from germs contained in manure, or from floating summer spores borne from some diseased plant grown in the neighborhood.”

Stem rot of carnations, W. E. BRITTON (*Amer. Florist*, 14 (1898), No. 545, pp. 431, 432).—Brief notes are given of an attack of *Fusarium* sp. on the stems of carnations, causing their rotting. The disease is not prevented by Bordeaux mixture and seems liable to attack snapdragons and antirrhinums. The author for the present recommends destroying all diseased plants and propagating only from healthy stock.

A disease of phlox, P. NYPELS (*Bul. Soc. Belge Micros.*, 24 (1897-98), pp. 123, 124).—Reports the occurrence of *Tylenchus devastatrix*.

A disease of the La France rose, H. C. HAAS (*Rosen Ztg.*, 13 (1898), No. 5, pp. 80, 81).—A brief report is given upon a disease which has been noted for at least four years on the La France rose. The author claims to have made a thorough examination of the roots of the plant and found them sound, and thinks that the disease is probably due to some fungus. The principal point of attack seems to be at the crown of the plant.

A monograph of the Peronosporaceæ, A. N. BERLESE (*Riv. Pat. Veg.*, 7 (1898), No. 1-4, pp. 19-37).—This is in continuation of a previous paper, and treats of the life history of the mildews, means of combating them, systematic arrangement, etc.

Infectious diseases of cultivated plants according to strict bacteriological methods, E. HALLER (*Die Pestkrankheiten der Kulturgewächse. Stuttgart: E. Nägele, 1898, 2. ed.*).

The bacteria of sorghum blight, F. F. BRUYNING (*Arch. Neerland. Sci. Exact. et Nat., 2. ser., 1 (1898), pp. 297-330, pls. 2; abs. in Jour. Roy. Micros. Soc., 1898, No. 5, p. 581*).—Two new species of bacteria are described from blighted sorghum. They are *Bacillus ruber oratus* and *Micrococcus aurantiacus sorghi*.

Notes of some plant diseases, G. POLLACCI (*Atti R. Univ. Pavia, 2. ser., 5 (1897), pp. 8; abs. in Ztschr. Pflanzenkrank., 8 (1898), No. 3, p. 171*).—The author notes the occurrence in the botanical garden of Pavia of the following parasitic diseases: *Macrosporium violæ*, on the leaves of violets. *Helminthosporium iberidis* on the leaves of *Iberis* sp., *Leptothyrium parasiticum* on the stems of the *Cereus stellatus* and *C. triangularis*, *Cytoporella cerci* on *Cereus* sp., *Pirostoma farnetianum* on *Pandanus utilis*, *Phyllosticta dammaræ* on the leaves of the *Dammara moori*, and *Helminthosporium lunaria* on the leaves of *Lunaria biennis*. The last-named fungus causes the total destruction of the fundamental parenchyma of the leaves, causing them to fall.

The principal nematodes found on agricultural crops, E. HENNING (*K. Landt. Akad. Handl. Tidskr., 37 (1898), No. 4, pp. 247-265, ill.*).

On the occurrence of *Heterodera schachtii* and *H. radicicola* in Russia, J. TARNANI (*Centbl. Bakt. u. Par., 2. Abt., 4 (1898), No. 2, p. 87; abs. in Ztschr. Pflanzenkrank., 8 (1898), No. 3, p. 165*).—The author reports the presence of *Heterodera schachtii* upon beets and also *Sinapis nigra*, *Poa annua*, *Trifolium repens*, *Medicago lupulina*, *Stellaria media*, *Solanum nigrum*, *Chenopodium polyspermum*, *Triticum repens* and *Sonchus oleraceus*. Of the last three plants their use as catch crops for beet nematodes can hardly be further recommended.

Upon the sugar beet the author found also *Heterodera radicicola*, *Dorylaimus* sp., and *Enechytraus* sp.

Heterodera radicicola has been reported in a number of places in different governments of Russia as occurring on sugar beets and *Oxalis stricta*, *Sonchus arvensis*, *Galinsoga parviflora*, *Papaver rhoeas*, and *Polygonum* sp.

Protection of fruit against parasitic fungi, A. TSCHOKKE (*Landw. Jahrb. Schweiz, 11, p. 153; abs. in Gard. Chron., 3. ser., 24 (1898), No. 621, p. 370*).—It is stated that pomaceous fruits are protected against invasions of such fungi as *Monilia fructigena*, *Penicillium glaucum*, *P. olivaceum*, *Mucor pyriformis*, and *M. stolonifer* by the transformation of the stomata into lenticles and by the presence of tannic and malic acids in the peripheral layers of cells.

A remedy for *Gloeosporium læticolor*, W. BUTTON (*Gard. Chron., 3. ser., 24 (1898), No. 603, p. 53*).—The author states that spraying grapes with methyl alcohol has proved successful in the destruction of this fungus. Care must be taken that the alcohol is not sprayed on the grapes so as to form drops on the berries, or it will produce decay. It is advised that the application be made either during a dull day, with little air stirring, or when the sun is not shining on the vines.

Treatment of plant diseases in 1896, F. D. CHESTER (*Delaware Sta. Rpt. 1897, pp. 20-38, figs. 4, dym. 5*).—This is a reprint of Bulletin 34 of the station (E. S. R., 9, p. 147).

Instructions for spraying, J. H. PANTON (*Rept. Agr. New Brunswick, 1897, pp. 209-222, figs. 13*).—Formulas for fungicides and insecticides are given and a number of injurious insects and fungus diseases are described.

On the contamination with copper through pressing of sprayed grapes, H. HOFFMANN (*Centbl. Bakt. u. Par., 2. Abt., 4 (1898), No. 9, pp. 369-376; 10, pp. 422-427*).

ENTOMOLOGY.

Preliminary notes on the codling moth, T. D. A. COCKERELL (*New Mexico Sta. Bul., 25, pp. 47-68*).—The bulletin gives the results of one year's observations on the codling moth in New Mexico. The life history of the insect at Mesilla is as follows: Moths appear toward the end

of April and lay their eggs on or near the small apples. A few small worms are found the second week of May and are numerous the latter half of May, some maturing by the last of the month. By the middle of June most of the first brood have left the apples, and by the last of the month some appear as moths. By July 10 the second brood of worms are working in full force. The third brood of worms are working by the second week of August, and by the third week some have pupated. By this time the broods are scarcely separable, since the late worms of the second brood are scarcely ahead of the early worms of the third. In September a partial fourth brood of worms appears, but the large proportion of the third brood winter as larvæ.

From observations with different varieties of apples the author believes it is still an open question whether the codling moth prefers one variety to another. In some cases there were great differences between individuals of one variety, old trees with rough bark being more affected than young smooth trees.

The insects pupate beneath the bark or in cracks on the trunks and limbs. A small proportion of the summer larva pupate in depressions on the fruit or between adjacent fruits.

The natural enemies of the codling moth are discussed. Among birds the most destructive to the insect are thought to be the 2 woodpeckers *Colaptes cafer* and *Picus scalaris*. Bats are thought to catch many of the moths. Hymenopterous parasites of the codling moth have not been found in the locality of the station, and have only rarely been found in other places in the State. The larva of a beetle, thought to be *Cymatodera cylindricollis*, is found in moderate numbers and preys on the codling worms after they hide under the bark of the trees. Several cases of a parasitic fungus similar to the chinch-bug fungus (*Sporotrichum globuliferum*) were found. On the whole, the author believes that only a limited amount of relief from the ravages of the codling moth is to be expected from its natural enemies.

The object of remedies in New Mexico is to prevent injury to the late apple crop, since the early crop is never seriously injured. Putting Paris green under bands on the trees in an attempt to poison the larvæ after they leave the fruit resulted in no success. Searching after worms on the trees in early spring gave fair results. Many of the worms were found, not under the bark, but in cracks in the partly dead wood of the trees, where they were safe from the attacks of birds. The author recommends, therefore, that all dead wood be cleared away and the cracks that remain be filled with wax or other suitable substance. He also emphasizes the importance of destroying worms in the storage house, and notes the case of a single cellar used as storage for apples in which over 5,000 worms were killed. Picking off and destroying wormy apples in the early summer was thought beneficial, but did not save the late crop. Trapping the larvæ under bands of paper placed about the tree trunks proved quite successful. Of 220 worms found on trees July 20, 204 were under bands. Pasturing hogs in the orchard to eat

the wormy windfalls is recommended. Spraying as ordinarily recommended is thought to be ineffectual. The author discusses the plan of destroying a year's fruit crop with the idea of exterminating the insect. In the locality of the station there were found no wild food plants on which the worms could subsist. The fact is noted that the early fruit, including all kinds of apricots, many peaches, plums, and cherries, and some apples would not have to be destroyed. This remedy would result in little good unless it were undertaken by all fruit growers.

A new orchard pest—the fringed-wing apple-bud moth, J. M. STEDMAN (*Missouri Sta. Bul.* 42, pp. 36-53, figs. 10).—The author reports the discovery of a new bud moth, which Mary E. Murtfeldt has referred provisionally to the genus *Nothris* and given the specific name *maligenmella*. The egg is oval, 0.6 mm. long and 0.35 mm. broad, of a uniform light yellow color, with the surface thrown into small shallow depressions and elevations which become larger and deeper at one end, in the center of which there is a protuberance or very short peduncle." The larvæ at first has a light-yellow color with shining black head and seal brown shield on the dorsal part of the first thoracic segment. The body is sparsely clothed with light-colored hairs. The true legs are brown and the five pairs of pro-legs are light yellow and are borne by the sixth, seventh, eighth, ninth, and last segments. When older the larvæ becomes light-greenish yellow in color with the shield on the dorsal part of the first thoracic segment shining black. When full grown it is about 8 mm. long and the color of the true legs, head, and shield become lighter until they are light yellow like the body. The pupa, inclosed in a thin, white, silken cocoon, "is 5.5 mm. in length and 2 mm. in width, of a uniform brown color and with a row of small, almost round depressions along each side of the sutures between the last five abdominal segments, and with indications of depressions in the form of markings along the sides of the other abdominal sutures." The moth is described by Mary E. Murtfeldt as follows:

"Alar expanse 14 to 15 mm. General color, satiny brownish buff with slight opalescence, and more or less leaden shading on thorax, wings, and body. Head buff, densely and somewhat shaggily scaled. Eyes prominent, purple black. Antennæ two-thirds as long as wings; basal joint conspicuously long and stout; second joint also long with the inner side peculiarly excavated. Palpi (labial) long recurved with short almost concealed basal joint, long slightly thickened second joint and slender tapering terminal. Thorax broad; patagia rather large, all anteriorly bordered with leaden gray. Forewings varying in color from almost clear buff to buff, so interspersed with the darker scales as to produce a 'smudged' effect; a small but distinct black discal dot and a group of five smaller, less clearly defined ones at the base of the terminal third constitute the ornamentation. Hind wings rather broad, somewhat paler and more lustrous than the primaries. Fringes concolorous with wing surface, also varying in intensity of the dark shadings. Body yellowish gray with bright-buff anal tuft. Legs agreeing in color with under surface, tibia, especially of hinder pair, densely clothed with long but oppressed hairs "

[The author says:]

"The moth is increasing rapidly and infesting new areas, but thus far it has been found in the western part of this State only, although it will, no doubt, soon become

general throughout Missouri and eastern Kansas. It accomplishes its injury in the spring by the larvæ eating into both the leaf and flower buds while they are unfolding, and ultimately causing them to drop at about the time, or shortly after, the flowers (petals) fall."

The following directions are given for combating the insect:

"Although this pest is a difficult one to combat owing to its habits of feeding within the young developing and unopened leaves, we were successful in holding it in check and in preventing the greater percentage of the fruit buds from being destroyed by early, thorough, and frequent applications of Paris green. The mixture to be used for this insect is: One pound of pure Paris green, 3 lbs. of fresh lime, and 150 gal. of water. The mixture must be constantly stirred while spraying, and the work done thoroughly on both sides of the tree. The first application is to be made as soon as the buds open and the green leaves first appear sufficiently to give the tree a green tinge, the second application about 5 days later, and the third at the time the first flower buds are about to open."

A new breeding cage used in the study of the fringed-wing apple-bud moth is described and illustrated.

The peach-twig borer, C. L. MARLATT (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 7-20, figs. 5*).—This article discusses the origin and distribution of the peach-twig borer (*Anarsia lineatella*), its characteristics, life history, and habits, natural parasites, remedies to be used against it, etc. It is pointed out that the strawberry-crown miner, which has been supposed to be identical with the peach-twig borer, is a distinct insect.

As a remedy the author recommends winter treatment with kerosene emulsion, resin wash, or some similar oily preparation which will penetrate the burrows and kill the young larvæ. The use of arsenical sprays in spring and fall is noted, but the operator is cautioned to use only weak sprays—1 lb. of the poison with an equal amount of lime in 200 gal. of water—to prevent scalding the very sensitive peach foliage. Removal and burning of withering infested tips of the trees in the spring as soon as injury is noted is thought to be often impracticable or even of doubtful utility.

A bibliography of the principal writings on the peach-twig borer is given.

The quince curculio, M. V. SLINGERLAND (*New York Cornell Sta. Bul. 118, pp. 695-715, figs. 10*).—The quince curculio (*Conotrachelus crataegi*) is considered the most serious enemy of the quince in New York. "During the past few years this quince curculio has caused a greater monetary loss to some of the larger quince growers in western New York than all the other insect foes and fungus diseases of the quince combined." The history, distribution, food, life history, habits, appearance, and natural enemies of the insect are given. It breeds in the wild haws and often attacks pears, but has a special liking for quinces. It is not known to breed in apples. Picking off and destroying infested fruit is impracticable, since it is often difficult without mutilating the fruit to determine whether it is infested. "The experience of some of our largest and most successful quince growers who

have cultivated their orchards thoroughly, both in the fall and spring, for several years proves quite conclusively that cultivation has but little, if any, effect in reducing the numbers of the curculio." Tests in an insectary indicated that the unsuccessful cultivation is due to the fact that the grubs bore back into the soil however often they may be disturbed. The chances of poisoning the insect by spraying are small. The egg is deposited in the flesh so that the larvæ can not be reached. The beetle can be poisoned only during the week or more spent in feeding on the fruit at the egg-laying period, and it gets most of its food in the flesh, eating only a minute hole through the skin. In the case of an orchard at Lockport, New York, hogs seemed to keep the insect in check. The author recommends the jarring method commonly used against the plum curculio as the most successful remedy known at present. A curculio catcher, especially adapted to the low-growing habit of the quince, is illustrated.

The San José scale in Missouri, J. M. STEDMAN (*Missouri Sta. Bul. 11, pp. 17-35, figs. 8*).—An inspection of the principal nurseries and some of the larger commercial orchards of Missouri is reported. The San José scale was not found in any nursery, but was present in twenty orchards, some of which are already completely ruined. In most cases the scale was introduced 7 years ago, one infection however occurring only 2 years ago. The distribution of the scale in Missouri as at present known is shown by a map. The scale is described and figured. As a remedy for the scale in orchards whale-oil soap, applied two or three times after the trees have been severely pruned, is strongly recommended.

Digestion in the larvæ of the gypsy moth, A. H. KIRKLAND and F. J. SMITH (*Agr. Massachusetts, 1897, pp. 391-401*).—The article notes the food materials of the gypsy moth, describes the moth's digestive system, and discusses its digestive processes.

"Microscopic examinations of the contents of different parts of the alimentary canal show that the greater part of the food retains much of its original physical character. The fibrous elements pass through the system practically unchanged. The softer tissues undergo a partial disintegration, but in general the cellular structure can be recognized. In the contents of the cells, however, there is a great change; in food removed from the anterior stomach the cell contents showed only a partial destruction, while in samples from near the intestine the protoplasm had nearly disappeared, only the chlorophyll granules remaining. From these examinations it appears that the process of digestion in this larva is practically one of solution or extraction; the digestive fluids dissolve the soluble proteids, carbohydrates, fats, salts, etc., while the insoluble parts are eventually ejected."

The alkalinity of the digestive fluids of the gypsy moth larvæ is ascribed to the presence of tri-potassium phosphate. Analyses of the alimentary canals of a number of lepidopterous larvæ showed that "phosphate of potash, although varying in amount, is a constant ingredient of the digestive fluids of leaf-eating Lepidoptera." The author believes that the function of this compound is "to aid in the osmosis of albuminoids through the walls of the alimentary canal into

the blood." Some lines of experiments with insecticides based on the presence of potassium phosphate in the digestive fluids of the gypsy moth larvæ are suggested.

Arsenate of lead: Its manufacture and chemical composition, F. J. SMITH (*Agr. Massachusetts, 1897, pp. 357-369*).—Arsenate of lead suitable for spraying is prepared from commercial grades of arsenate of soda and either acetate of lead or nitrate of lead. The proportions and properties of these ingredients are described. The lead oxid content was found to vary from 58.81 per cent to 66.795 per cent in 8 samples of acetate of lead, and from 66.37 per cent to 68.37 per cent in 3 samples of nitrate of lead. Four samples of arsenate of soda showed a variation of 36.77 per cent to 47.8 per cent in arsenic pentoxid. It also varied in percentages of chlorin and other foreign substances. The chemical composition and properties of arsenate of lead and the chemical actions involved in the preparation are given in detail. Formulas are given for computing the quantities of acetate of lead and arsenate of soda required to prepare a given quantity of arsenate of lead.

Danger from the use of arsenate of lead, A. H. KIRKLAND (*Agr. Massachusetts, 1897, pp. 390-393*).—Analyses were made of the urine of men engaged in extensive spraying operations against the gypsy moth.

"The results of these analyses show conclusively that in some cases men engaged in spraying acquire dangerous amounts of arsenic. That actual sickness resulting from this work is rare is shown by the fact that but few of our many employees lost time from this cause. . . . It may be stated, in general terms, that while an occasional person may become poisoned during extensive spraying operations with arsenate of lead, premonitory symptoms appear in ample time for a change of work to be arranged; and since the conditions existing in the work against the gypsy moth are exceptional, the farmer or fruit grower may use this insecticide with less fear of danger from poisoning than is the case where Paris green or London purple is used. In all cases proper care must be taken in handling the poison and in preventing the exposure of the skin to the spray."

Concerning the direct combating of phylloxera on stock, C. MOHR (*Ztschr. Pflanzenkrankh., 8 (1898), No. 2, pp. 69, 70*).—The author recommends the use of 0.5 liter benzolin in 100 liters of water, to be made neutral to litmus paper with sulphuric acid. This mixture is to be poured about the roots of the infected plants, 10 to 15 liters being used for each plant. It is further stated that this solution can be used with benefit for destroying various forms of plant lice on many other plants.

Experiments with insecticides, A. H. KIRKLAND and A. F. BURGESS (*Agr. Massachusetts, 1897, pp. 370-389*).—Both indoor and outdoor tests of the relative value of various insecticides in killing gypsy moth larvæ are reported. The data obtained are reported in tabular form. Some of the conclusions are as follows:

"While arsenic seems slightly superior to Paris green so far as killing effects are concerned, its high specific gravity renders it difficult of suspension in water, and hence it can not be applied evenly to the foliage. . . . Experiments with chemically

pure arsenite of lead *v.* arsenate of lead mixture (containing in reality only about 50 per cent chemically pure arsenate of lead) show the relative superiority of the latter. The specific gravity of the arsenite of lead is much greater than that of the arsenate, and for this reason it can not be so evenly applied to the foliage. . . . The experiments with barium arsenate in 1896 gave so good results that we were hopeful that this insecticide would prove superior to lead arsenate. Its killing effects on larvae in confinement are certainly superior to those of arsenate of lead. In the field spraying operations it was found that the poison did not adhere to the foliage for a sufficiently long time to kill the larvae. With the lessening of the cost of arsenate of lead we have now effected, barium arsenate can not compete with it."

Phenolate of lead had no effect on larvae or foliage. Di-plumbic arsenate seemed equal if not superior to tri-plumbic arsenate.

Some spraying mixtures, G. W. CAVANAUGH (*New York Cornell Sta. Bul.* 149, pp. 719-721).—Chemical examination of 5 samples of Paris green showed from 54.32 to 55.32 per cent of arsenic, and an analysis of English purple showed 36.75 per cent of arsenic and 5.36 per cent of arsenic soluble in water. Two samples of Paris purple gave a total of 34.1 and 47.05 per cent of arsenic and 13.88 and 11.86 per cent of arsenic soluble in water.

An analysis of laurel green gave 10 per cent copper and 7.75 per cent arsenic (As_2O_3). Several analyses of Bug Death are given, which show that it contains no arsenic, but is made up of zinc 76.5 per cent, lead 9.8, and iron oxids 7.8 per cent, a very small amount of phosphoric acid and potash (2 per cent). The last 2 constituents give Bug Death a slight fertilizing value.

Animal parasites, R. HELM (*Producers' Gaz. and Settlers' Rec.* [West Australia], 5 (1898), No. 3, pp. 189-194, figs. 7).—A description and life history is given of bot flies of cattle (*Hypoderma bovis* and *Hypoderma lineata*) and camel bot (*Cephalomyia maculata*).

The evolution of *Hypoderma bovis*, according to new investigations, L. GEDDELST (*Rev. Gén. Agron.*, 7 (1898), No. 11, pp. 494-496).

The life history of *Hypoderma bovis*, SCHNEIDTEMÜHL (*Centbl. Bakt. u. Par.*, 1. Abt., 24 (1898), No. 1, pp. 30, 31).

The Buffalo gnats, or black flies, of the United States, D. W. COQUILLET (*U. S. Dept. Agr., Division of Entomology Bul.* 10, n. ser., pp. 66-69, figs. 2).—Descriptions and synopsis of the family Simuliidae.

Further notes on the house fly, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Bul.* 10, n. ser., pp. 63-65).—Experiments in mixing various substances with horse manure in order to prevent the breeding of house flies in it are reported. It was found that nothing was to be gained by the use of air-slaked lime, land plaster, or gas lime. Both chlorid of lime and kerosene were successfully used, and the author expresses the belief that the latter is an easy and cheap method of treating manure piles to prevent the breeding of house flies.

The cecidomyiids of cereals and their parasites, P. MARCHAL (*Ann. Soc. Ent. France*, 66 (1898), No. 1, pp. 1-105, pls. 8, figs. 9; *abs. in Zool. Centbl.*, 5 (1898), No. 18-19, pp. 618-620).—Studies were made of *Mayetiola* (*Oligotrophus*) *destructor*, *M. avenae*, *Cecidomyia cerealis*, *C. culmicola*, *C. frumentaria*, *Diplosis tritici*, *D. mosellana*, *D. equestris*, *D. marginata*, *D. flava*, *D. cerealis*, *Lasioptera cerealis*, and *Epidosis cerealis*; the most of the studies being made on the first species.

Among the parasites mentioned are: *Trialeis remulus*, *Polygnotus minutus*, *P. zozini*, *Eupelmus atropurpureus*, *Merisus destructor*, and *Homoporus laniger*.

The Hessian fly in Sweden (*Cecidomyia tritici*), H. TEDIN (*Landtmannen*, 9 (1898), No. 35, pp. 559-561).

Insects injurious to the cranberry and other fruits, C. H. FERNALD (*Agr. Massachusetts*, 1897, pp. 144-162).—The greater part of the damage to cranberries in Massachusetts is caused by the following 3 insects: The vine worm (*Rhopobota vacciniana*), the fruit worm (*Mincola vaccinii*), and the cranberry spanworm (*Ematurga faronii*). The habits of these insects are discussed and remedies for them suggested. A few other cranberry insects of less importance are noted. The author also discusses plant lice and the San José scale and suggests treatment.

Two Japanese insects injurious to fruit, M. MATSUMURA (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 36-40, figs. 2*).—The apple-fruit borer (*Laverna herellera*) and the pear-fruit borer (*Nephoptyx rubizonella*) are described and notes are given on remedies.

The peach-twig borer, C. L. MARLATT (*U. S. Dept. Agr., Farmers' Bul. 80, pp. 15, figs. 5*).—This is a revised reprint from U. S. Dept. Agr., Division of Entomology, Bulletin 10, new series (see p. 565).

Three shade-tree insects, A. H. KIRKLAND (*Agr. Massachusetts*, 1897, pp. 238-247, figs. 5).—The author discusses the sugar-maple borer (*Plagionotus speciosus*), the oak pruner (*Elaphidion villosum*), and the imported elm-bark louse (*Gossyparia ulmi*), considering such points as life history, injury, natural enemies, remedies, etc.

Notes on the strawberry weevil: Its injuries and bibliography, F. H. CHITTENDEN (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 82-87*).

The fig eater, or green June beetle, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 20-26, fig. 1*).—This gives notes on the characteristics and habits of the green June beetle (*Allorhina nitida*). It is shown, contrary to the general belief, that the normal food of the larvæ of this beetle is the vegetable mold of rich soils and that in its larval stage it is not a crop pest.

Scale insects, A. M. LVA (*Producers' Gaz. and Settlers' Rec. [West. Australia] 5 (1898), No. 6, pp. 465-483, pls. 3, figs. 15*).—Notes are given on the San José scale (*Aspidiotus perniciosus*), red scale (*A. aurantii*), greedy scale (*A. rapar*), black aspidiotus (*A. rossi*), mussel scale (*Mytilaspis pomorum*), mussel scale of citrus fruits (*M. citricola*), black scale (*Lecanium olea*), broad or soft scale (*L. hesperidum*), cottony-cushion or fluted scale (*Icerya purchasi*), mealy bugs (*Dactylopius* spp.), etc.

The subject of parasitism of scale insects is discussed at some length and various remedies suggested for the destruction of the scales by means of washes and emulsions.

Monograph of the genus Aspidiotus, G. LEONARDI (*Riv. Patol. Veg.*, 7 (1898), No. 1-4, pp. 38-86, figs. 18).

American scale insects as a menace to European fruit culture, A. BERLESE and G. LEONARDI (*Riv. Patol. Veg.*, 6 (1898), No. 11-12, pp. 321-352, figs. 21).

Scale insects on cacti, KÜHLGATZ (*Monatsschr. Kakteenkunde*, 8 (1898), No. 11, pp. 106-170, pl. 1).—One of a series of articles on scale insects, together with a description of *Rhizococcus multispinosus* nov. spec.

Destructive locusts in 1897, W. D. HUNTER (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 40-53*).—This is a report of observations made in an exploration of the territory within the limits of the permanent breeding ground of the Rocky Mountain locust and adjoining territory. The activity of the Rocky Mountain locust throughout the entire breeding region was greater than for many years. The species was present in northwestern Wyoming, the larger part of South Dakota, and the northern half and western third of Nebraska, the situation being serious in some of these places, especially South Dakota. The nonmigratory locust was unusually abundant in South Dakota, Nebraska, and parts of Oregon and Washington.

The tobacco flea-beetle, F. H. CHITTENDEN (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 79-82, fig. 1*).—This gives recent observations on the larval habits

of the tobacco flea-beetle (*Epitrix parvula*), a description of the larvæ and pupa and notes on the published habits and injuries of this insect.

On the habits of the **Oscinidæ** and **Agromyzidæ** reared at the **United States Department of Agriculture**, D. W. COQUILLET (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 70-79*).

Notes on cucumber beetles, F. H. CHITTENDEN (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 26-31, figs. 2*).—The striped cucumber beetle (*Diabrotica vittata*) and the twelve-spotted cucumber beetle (*D. 12-punctata*) are described and notes are given on their life history and habits.

Insects that affect asparagus, F. H. CHITTENDEN (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 54-62, fig. 1*).—This consists of brief notes on numerous species of lepidoptera and hemiptera found on asparagus and more extended notes on the common asparagus beetle (*Crioceris asparagi*) and twelve-spotted asparagus beetle (*C. 12-punctata*).

The sugar-cane borers of Java, L. ZEHNTNER (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 32-36, figs. 4*).—This is a résumé of the results of studies made at the experiment station at Paseroean, Java, during the past few years. The results were published in the *Mededeelingen van het Proefstation Oost Java*.

The following borers are considered: *Diatraea striatalis*, *Scirpophaga intacta*, *Chilo infuscatellus*, and *Grapholitha schistaceana*.

The pine geometer moth (Fidorcia pinaria), S. MACDOUGALL (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 9 (1897), pp. 106-123, figs. 3*).—Description, life history, and food habits of this insect are given and remedial measures are suggested.

Two parasites of sugar cane, E. BORDAGE (*Rev. Agr. Reunion, 2 (1898), No. 4, pp. 400-403*).—Notes the occurrence of larvæ of *Dendroneura sacchari* and *Grapholitha schistaceana* in cane.

Report of the State Board of Agriculture on the work of extermination of the gypsy moth (Agr. Massachusetts, 1897, pp. 307-350, pls. 4).—This contains the reports of the financial agent, the entomologist, and the field agent of the Board of Agriculture of Massachusetts. The article reports what has been done in the work of extermination of the gypsy moth and describes the present conditions of the infected regions.

Notes on predaceous beetles, A. F. BURGESS (*Agr. Massachusetts, 1897, pp. 402-411*).—Notes are given on the life history and habits of several beetles which prey upon the larvæ of the gypsy moth.

The species of Podisus occurring in the United States, A. H. KIRKLAND (*Agr. Massachusetts, 1897, pp. 412-419, pl. 1*).—Descriptions of the species *Podisus* occurring in the United States and notes on their habits are given, together with a synopsis of the species, synonymy, etc.

Danger of importing insect pests, L. O. HOWARD (*U. S. Dept. Agr. Yearbook 1897, pp. 529-552, figs. 19*).—Of the 73 species of insects most injurious in the United States 37 have been undoubtedly introduced from foreign countries. The great majority of introduced species have come from Europe. The author regards nursery stock as the most dangerous means of importation of insect pests. Foreign insects liable to be imported are figured and discussed.

Notes from correspondence (U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 97-99).—Brief miscellaneous notes, taken from correspondence, on the following subjects: *Datana angusii* injuring pecans in Mississippi; abundance of *Catocala lacrymosa* at Brookhaven, Mississippi; the pear-tree borer in Mississippi; remedy for cabbage worms; the rice grub beetle at electric lights in New Orleans; injury by the bark beetle (*Dendroctonus rufipennis*); injuriousness of *Pieris protodice*; injury by the silver-pine tortricid to Douglas spruce in Oregon; *Heterocampa mauteo* on oak; the malodorous carabid (*Nomius pygmaeus*) in Oregon; voracity of *Hippodamia glacialis*; injury to chrysanthemums by *Corythuca irrorata*; a psyllid (*Trioza diospyri*) injuring Chinese persimmons; plant-lice injury to tomato; parasites of goats; the house crab spider as a destroyer of flies, and a wasp parasite.

General notes (*U. S. Dept. Agr., Division of Entomology Bul. 10, n. ser., pp. 87-97, fig. 1*).—A peculiar damage to the fruit of the apple from an unknown species of leaf miner is noted. A new case of an insect boring into lead is reported. Notes are given on *Icerya purchasi* in Portugal and the Azores; a little-known tineid moth of indoor habits; a moth likely to be mistaken for *Tinea granella*; parasites of bean and cowpea weevils; injury by the western flea-beetle, *Phyllotreta pusilla*, the wind-row remedy for blister beetles; white grubs of *Allorhina nitida* invading a cellar; reported damage by the green plant-bug, *Lioderma uhleri*; on the food habits of the harlequin cabbage bug; food plants of the "cotton stainer;" collecting locust eggs in Morocco; poisoning grasshoppers in Natal, and collecting grasshoppers in New Hampshire.

Report of the director of the Entomological Institute of Sweden for 1897, S. LAMPA (*Meddel. K. Landtbr. Styrs., 1898, No. 46, pp. 48, figs. 9*).

Report of the entomologist, G. H. POWELL (*Delaware Sta. Rpt. 1897, pp. 198-210*).—A brief note is given on the study of the strawberry root-louse (*Aphis forbesi*) and Bulletin 33 of the station is reprinted (*E. S. R., 9, p. 73*) with the addition of some data collected since its publication.

Insecticides, KITCHEN (*Florists' Exchange, 10 (1898), No. 52, p. 1258*).—A discussion of methods of applying various insecticides and of their action on the insects and plants treated and on the operator.

FOODS—ANIMAL PRODUCTION.

Fresh and refrigerated meats, A. GAUTIER (*Rev. Hyg., 19 (1897), pp. 289-303; 391-415*).—On the basis of statistics of the amount of food brought into Paris between the years 1880 and 1890 the daily amount consumed per man is calculated. A study is reported of fresh and refrigerated or frozen beef and mutton. The preserved mutton and beef came from the Argentine Republic, and had been frozen from five to six months. The samples analyzed were freed as far as possible from tendon and visible fat. The results follow:

Composition of fresh and refrigerated beef and mutton.

	Mutton (shoulder and neck), fresh.	Beef (rump steak), fresh.	Refrigerated mutton.	Refrigerated beef.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Water.....	74.92	74.75	73.66	73.96
Globulin (with a little albumen) in the portion of meat soluble in water.....	3.32	3.06	2.14	2.69
Pre-existent peptones.....	1.33	2.24	1.29	2.56
Myosin.....	8.31	10.96	10.33	9.29
Myostroin.....	4.49	4.30	4.94	6.41
Indigestible matter (elastin, keratin, etc.).....	.86	.24	.75	.94
Extractive materials (ferments, leucomaines, etc.).....	.49	.97	.95	1.01
Glycogen.....	.40	.38	.03	.16
Fat and cholesterin.....	5.23	1.97	5.38	2.04
Soluble salts.....	.60	.65	.53	.47
Insoluble salts.....	.65	.44	.44	.44
Total.....	100.52	99.96	100.24	100.02

In addition, the author made the following determinations in the same samples of meat:

Constituents of fresh and refrigerated beef and mutton.

	Mutton (fresh).	Beef (fresh).	Mutton (refrig- erated).	Beef (refrig- erated).
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Dry matter in material soluble in cold water.....	5.84	6.92	5.34	6.99
Dry matter in material soluble in cold water after removal of albumen and globulin by coagulation by heat.	2.523	3.86	3.20	4.50
Dry matter in bouillon obtained by boiling chopped meat in an excess of water.....	3.37	3.98	3.62	5.17
Reducing substance calculated as glycoses.....	.191	.24	.17	.11
Gelatine obtained by heating portions insoluble in water 6 hours at 115°.....	2.72	2.56	2.69	2.15
Nucleinic acid.....	.56	.44	.59	.66
Acidity of aqueous extract of 100 gm. meat calculated as sulphuric acid.....			.38	.40

The different constituents of the samples are discussed in some detail. According to the author, the mineral matter in the fresh mutton and beef had the following composition:

Composition of ash of fresh mutton and beef.

	Mutton.	Beef.
	<i>Per cent.</i>	<i>Per cent.</i>
Soluble portion:		
Potassium chlorid.....	0.103	0.112
Sodium chlorid.....	.021	.023
Potassium sulphate.....	.050	.055
Potassium phosphate (PO ₄ K ₂ H).....	.383	.409
Calcium phosphate.....	.010	.018
Magnesium phosphate.....	.033	.036
Insoluble portion:		
Calcium phosphate.....	.650	.440
Magnesium phosphate.....		
Total	1.250	1.093

A kilogram of beef was boiled for a long time in 2,500 cc. of water. One liter of beef bouillon contained 18.4 gm. dry matter, made up as follows:

	Grams.
Peptones and propeptones.....	5.3
Gelatinoids.....	2.6
Creatin and similar bases.....	1.8
Other bases.....	.2
Inosit and glycogen.....	1.4
Various extractives.....	2.6
Mineral salts.....	1.5
Total	18.4

The juice which exuded from fresh and frozen meat when it was allowed to stand was also studied in some detail. More juice was obtained from beef than from mutton. Thus, when a kilogram of beef was exposed to the air three days at a temperature of 13-14° C., 33 cc. of juice was obtained; from refrigerated beef 113 cc., and from refriger-

ated mutton 58 cc. This meat juice has the following percentage composition:

	Per cent.
Globulins precipitated by an excess of a saturated solution of ammonium sulphate.....	4.23
Albumin coagulable at 100° after removal of the globulins.....	1.20
Peptones.....	3.47
Collagen, coagulable at about 37°.....	.49
Other organic materials, ferments, etc.....	.45
Soluble salts.....	1.29
Insoluble salts.....	.06
Water.....	88.81
Total.....	100.00

Somewhat extended experiments by methods of artificial digestion are also reported with the different sorts of meat. From the investigation as a whole the author's principal conclusion is that the importation of refrigerated meat should be increased, since such meat is of satisfactory composition, is easily digestible, and may be kept for an indefinite time. The economic importance of refrigerated meat is discussed at some length.

Nutrition investigations in New Mexico in 1897, A. GOSS (*U. S. Dept. Agr., Office of Experiment Stations Bul. 54, pp. 20, pl. 1, dgm. 1*).—This is a continuation of work previously reported (*E. S. R.*, 9, p. 264). A detailed study was made of the composition of a side of beef taken from a steer representing as nearly as possible the average animal raised upon New Mexico cattle ranges. A dietary study was also made with one of the families previously studied. The usual methods were followed. The nutrients consumed per man per day were protein 85 gm., fat 71 gm., and carbohydrates 563 gm., with a fuel value of 3,320 calories. The cost was 7.1 cts. The total expenditure for food during 14 days of the dietary study was \$2.78. Of this only 21 cts. was expended for food accessories, coffee being the only such article purchased. The waste was estimated to cost but 4 cts. It is noted that the diet falls below the commonly accepted standard in both protein and energy.

Deep stalls and ordinary stalls for steers, together with feeding experiments with molasses peat and molasses bran, F. ALBERT (*Landw. Jahrb.*, 27 (1898), Nos. 1-2, pp. 174-188).—General statements are made concerning the animals fed at the experiment farm at Lauchstädt, and a number of feeding experiments are reported. A test, beginning June 29, 1896, and covering two periods of 49 and 66 days, was made with 24 steers, divided into 2 equal lots. One steer was dropped from each lot before the close of the test. The average weight of the steers was 400 to 500 kg. They were purchased at some distance from the station, and lost 44.23 kg. each during transportation. Lot 1 was kept in deep stalls (see p. 574) and lot 2 in ordinary stalls. During the preliminary period of 14 days the steers were fed a ration of hay and

beet chips, with wheat bran in addition, the amount being increased from 2 to 4 kg. per 1,000 kg. live weight.

During the first period both lots were fed a ration consisting of 5 kg. alfalfa hay, 8 kg. straw and hay, 8 kg. dried-beet chips, 8 kg. molasses bran, and $3\frac{1}{3}$ kg. cotton-seed meal per 1,000 kg. live weight. This was calculated to furnish 3.01 kg. nitrogenous material and 14.97 kg. digestible nitrogen-free material, including fat. The daily average gain of lot 1 was 1.49 kg. and of lot 2, 1.265 kg. The loss of weight during transportation was made good in 37 days.

During the second period the steers were fed a basal ration of 5 kg. alfalfa hay, 8 kg. straw and chaff, 8 kg. dried beet chips, and 3 kg. cotton-seed meal per 1,000 kg. live weight. In addition, 6 animals in lot 1 and 5 in lot 2 were fed 6 kg. of molasses peat and 6 kg. of molasses bran. Five animals in lot 1 and 6 in lot 2 were given 12 kg. of molasses bran. It was calculated that both rations furnished 3.08 kg. digestible nitrogenous material and 17.28 kg. nitrogen-free material.

The variations in weight of each steer are recorded. The steers in deep stalls fed molasses peat made an average daily gain of 0.88 kg. and those fed molasses bran 7.27 kg. Those kept in ordinary stalls fed molasses peat made an average gain of 1.121 kg. and those fed molasses bran of 1.303 kg. The two molasses feeds were about equal. In the first period the deep stalls seemed superior and in the second period the reverse was true.

At the close of the test the steers were sold and slaughtered. The weight of the carcass and organs is recorded for 3 steers. Body measurements were also taken.

The financial statement is based on alfalfa hay at \$1.20, chaff and straw at 48 cts., beet chips at \$1.83, peat molasses at 96 cts., cotton-seed meal at \$2.92, wheat bran at \$2.26, and molasses bran at \$1.51 per 100 kg. The steers were purchased at 15.8 cts. and sold at 16.8 cts. per kilogram. Without taking account of the manure it was calculated that the steers gave a profit of \$177.24. The value of the manure is discussed.

Feeding experiment No. 2 with steers, F. ALBERT (*Landw. Jahrb.*, 27 (1898), No. 1-2, pp. 203-208).—In continuation of work reported above, a test was made with 14 steers $2\frac{1}{2}$ to 3 years old fed in deep stalls until they were fit for market. The test began November 6, 1896, and covered 197 days. The first 14 days were regarded as a preliminary period. During this time the steers were fed per 1,000 kg. live weight, 60 kg. fodder beets, 5 kg. alfalfa hay, 3 kg. meadow hay, 8 kg. barley straw, 1 kg. cotton-seed meal, and 2 kg. wheat bran. This was calculated to furnish 1.977 kg. digestible protein and 12.545 kg. digestible nitrogen-free material. During the feeding experiment proper the ration per 1,000 kg. live weight consisted of 60 kg. fodder beets, 5 kg. alfalfa hay, 2.5 kg. meadow hay, 8 kg. barley straw, 3 kg. cotton-seed meal, and 8 kg. molasses bran (molasses and bran 1:1). This furnished 3.123 kg. digestible protein and 17.149 kg. nitrogen-free material. During transportation to the station the steers lost 54.8 kg.

each. This was made good in 47 days. The gains in weight of the different steers are recorded. The daily gain per steer during the test was 0.727 to 0.882 kg.

The financial statement is based on fodder beets at \$1.92, beet chips at \$1.68, alfalfa hay at \$1.20, meadow hay at \$1.20, barley straw at 48 cts., cotton-seed meal at \$2.92, wheat bran at \$2.25, and molasses bran at \$1.51 per 100 kg. The steers were purchased at 16.3 cts. and sold at 17.3 cts. per kilogram. Without taking into account the manure the steers gave a profit of \$177.24.

Fattening lambs in winter, T. SHAW (*Minnesota Sta. Bul.* 57, pp. 416-167, figs. 1).—This is a continuation of previous work of the station (E. S. R., 8, p. 251).

Fattening Minnesota lambs (pp. 417-434).—A test was made with 100 lambs to compare combinations of coarse grains grown in the State and to compare limited and unlimited rations. Five of the lambs were home-grown; the rest were purchased in Minnesota at 3½ and 4 cts. per pound. After the lambs were received at the station they were pastured and given some oats in addition until the beginning of the test. The test, which was preceded by a preliminary period of 7 days, began December 30, 1895, and covered 77 days. The lambs were divided into 5 lots of 20 each. Lot 1 was fed unlimited amounts of linseed cake, corn, and oats 1:3:6. Lot 2 was fed all they would eat up clean of the same ration. Lot 3 was fed a like amount of linseed cake, barley, and oats 1:3:6. The same ration was fed to lot 4 for the first 6 weeks of the experiment, but during the last 5 weeks the proportion of the different feeding stuffs was changed to 2:3:5. During the first 6 weeks of the test lot 5 was fed all they would eat up clean of linseed cake and oats 1:9. In the latter part of the experiment the proportion was changed to 2:8. During the first 6 weeks of the test all the lots were fed native hay which was of poor quality. During the last six weeks of the test, hay of good quality, consisting almost entirely of clover, was fed. The linseed cake was fed in pieces about the size of a pea. The hay was fed whole and the grain was unground. About 21 days were required to get the lambs onto full feed. The financial statement is based on linseed cake at \$14 per ton; corn, 18 cts. per bushel of 56 lbs.; barley, 16 cts. per bushel of 48 lbs.; oats, 14 cts. per bushel of 32 lbs.; and native hay at \$3 and clover hay at \$3.50 per ton. The results of the test are summarized in the following table:

Summary of results of feeding Minnesota lambs.

	Total food consumed.		Average weight at beginning.	Average gain per lamb.	Profit per lot.
	Grain.	Hay.			
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	
Lot 1	3,821	900	96.4	31.6	\$5.90
Lot 2	3,710	1,459	99.6	31.3	11.60
Lot 3	3,645	1,355	96.9	30.2	10.91
Lot 4	3,655	1,361	99.1	31.8	11.74
Lot 5	3,695	1,236	99.2	30.2	9.08

Fattening range lambs (pp. 435-461).—A test was made with 120 Montana range lambs to learn whether such lambs could be profitably fattened under ordinary farm conditions. After a preliminary period of 6 days, the test proper began November 16, 1896, and covered 84 days. The lambs weighed on an average 57.2 lbs. and cost in Montana on an average \$1.25 per head. Lot 1 was fed linseed cake, wheat bran, corn, and oats 1:2:3:4; lot 2, oil cake, bran, barley, and oats in the same proportions; lot 3, bran, linseed cake, barley, and oats in the same proportions; lot 4, linseed cake and oats 1:9. All the lambs were given native hay in addition to the grain ration. They were fed in sheds with yards. The financial statement is the same as in the previous statement with the addition of bran at \$6.50 per ton. The principal results are shown in the following table:

Summary of results of feeding Montana range lambs.

	Total food consumed.		Average weight at beginning.	Average gain per lamb.	Profit per lot.
	Grain.	Hay.			
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	
Lot 1.....	5,127	1,208	58.1	19.0	\$30.16
Lot 2.....	4,974	1,200	57.0	18.5	29.37
Lot 3.....	5,127	1,196	57.0	22.7	32.98
Lot 4.....	4,771	902	57.2	18.9	28.35

A second test, under practically the same conditions as the preceding experiment, was made with 120 lambs divided into 4 lots of 30 each. The test, which was preceded by a preliminary period of 7 days, began November 8, 1897, and covered 112 days. The lambs weighed on an average 55½ lbs. when purchased. Lot 1 was fed linseed cake, wheat bran, and oats 1:2:3:4; lot 2, linseed cake, bran, barley, and oats in the same proportion; lot 3, bran, oats, and barley 3:3:4; lot 4, oil cake, bran, and oats 1:2:7. In addition, all the lots were fed mixed hay, in which clover predominated, and sorghum silage. The financial statement is based on linseed cake at \$22 per ton, wheat bran \$7.50 per ton, corn 22 cts. per bushel of 56 lbs., barley 20 cts. per bushel of 48 lbs., oats 17 cts. per bushel of 32 lbs., mixed hay, clover, and timothy \$4, and sorghum silage \$1.20 per ton. The results are summarized in the following table:

Summary of results of feeding Montana range lambs.

	Total food consumed.			Average weight at beginning.	Average gain per lamb.	Profit per lot.
	Grain.	Hay.	Silage.			
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	
Lot 1.....	6,330	2,771	1,024	61.6	35.1	\$56.20
Lot 2.....	6,256	2,773	1,026	61.2	31.8	50.81
Lot 3.....	6,005	2,735	1,034	61.4	29.1	51.55
Lot 4.....	6,252	2,655	1,026	60.4	35.7	51.76

The author discusses the tests as a whole and draws the following general conclusions:

“(1) Both range lambs and home-grown lambs are well adapted for feeding.

“(2) The value of the increase made from feeding lambs in our State is more than the cost of the food used in making it.

“(3) The coarse cereals which Minnesota produces are well adapted to the fattening of lambs when suitably blended.

“(4) When lambs are being fattened, considerably superior gains will be obtained when the grain food contains at least 10 per cent of oil cake.

“(5) Oil cake, barley, and oats, suitably blended, with or without bran, makes an excellent grain food for fattening lambs.

“(6) While good gains may be secured by feeding oats and oil cake, suitably blended, the dearth of the mixture makes it too costly to furnish the highest profit.

“(7) Excellent gains can be secured when fattening lambs in our climate in the absence of field roots or silage.

“(8) Under the conditions which have prevailed during the past three years, an average of about \$1 per head could be secured from feeding lambs judiciously for about 100 days.”

Peanuts, cowpeas, and sweet potatoes as food for pigs, J. F. DUGGAR (*Alabama College Sta. Bul. 93, pp. 115-134*).—*Feeding experiments with peanuts* (pp. 117-121).—Immediately after weaning 6 Poland China pigs were hurdled on a field of Spanish peanuts and given some shelled corn in addition. The test began in September and covered 6 weeks. The peanuts were eaten readily from the first and as long as the vines remained green a considerable portion of the leaves was also eaten. The yield of peanuts was 62.6 bu. per acre. The 6 pigs weighed at the beginning of the test 184.3 lbs., and gained 196.4 lbs., consuming 373 lbs. of shelled corn, besides the peanuts and some foliage from 7,673 sq. feet. That is, 1.4 lbs. of peanuts and 1.9 lbs. of corn, together with an unknown quantity of peanut foliage, were consumed per pound of gain. Valuing the corn at 40 cts. per bushel and the pork at 3 cts. per pound, the profit from the peanuts was \$3.23 or at the rate of \$18.34 per acre. The author points out that this was poor sandy upland which would not have produced over 200 lbs. of lint cotton per acre worth \$10 to \$12. The expense of cultivating the peanuts was less than for a similar area of cotton and in addition the soil was benefited by the manure and the peanut vines.

To compare peanut pasturage and corn meal a second test was made with 6 Essex pigs of about the same age, divided into 2 lots. Lot 1 was hurdled on peanuts which were planted the last of June following wheat, and given as much corn in addition as the pigs would eat. Lot 2 was hurdled on peanuts but given no grain. After a preliminary period of a week the test began November 4 and continued 4 weeks. Lot 1 grazed over 2,025 sq. ft. of peanuts and gained 38.6 lbs., consuming 2.06 lbs. of corn per pound of gain in addition to the peanut forage. Valuing the corn and pork at the prices given above, the peanuts yielded a profit of \$10.94 cts. per acre. Lot 2 grazed over

3,517 sq. ft. of peanuts, making a gain of 21.1 lbs. This was equivalent to a profit of \$7.83 per acre. In the author's opinion, owing to an exceedingly dry summer, the yield of peanuts was only about half what it would have been under usual conditions. He believes that pigs under 100 lbs. weight would make pork worth from \$12 to \$20 on an acre of peanuts, provided they were fed a moderate allowance of corn or corn meal in addition.

In the third test unhulled peanuts and corn meal were compared. For 6 weeks the 2 lots of pigs used in the previous test and a third lot of the same age and breed were fed the following rations: Lot 1 unhulled peanuts and corn meal, equal parts; lot 2 peanuts alone, and lot 3 corn meal. The gains made by the 3 lots were 84, 59.5, and 8.6 lbs., respectively. The food consumed per pound of gain by the corresponding lots was 3.7, 2.8, and 10.7 lbs. The author calculates that when fed peanuts alone the young pigs were able to make a growth of 9 lbs. per bushel of peanuts, equivalent to a profit of 27 cts. per bushel. Although the addition of corn to the peanut ration increased the gains, they were produced at a greater cost. The pigs fed exclusively on corn gave very poor returns. In the author's opinion this test shows the bad effects of long-continued feeding of corn alone.

Feeding experiments with cowpeas (pp. 122-125).—Six Essex pigs of the same litter were divided into 2 lots of 3 each. Lot 1 was fed shelled corn *ad libitum*, and lot 2 was huddled on a field of cowpeas and given corn in addition. The test covered 6 weeks and was preceded by a preliminary period of 7 days. At the beginning of the test the leaves of the cowpeas were all green and only about half the peas seemed mature, although the others had attained full size. While the leaves remained green they were readily eaten. In the latter half of the experiment only the peas were eaten. Both lots of pigs received salt and wood ashes. The lots averaged about 150 lbs. at the beginning of the test. Lot 1 gained 45.2 lbs., consuming 263.8 lbs. of corn, or 5.86 lbs. per pound of gain; and lot 2 gained 122 lbs., consuming 374 lbs. of corn, or 3.07 lbs. per pound of gain. Lot 1 grazed over 7,280 sq. ft. On the basis of the yield from a similar field, this area would have produced 132 lbs. of cowpeas. In other words, 1.1 lbs. of cowpeas were consumed per pound of gain in addition to corn, or a total of 4.17 lbs. of corn and cowpeas. It was calculated that the cowpeas would return \$10.65 per acre in pork. This, in the author's opinion, is not a large return, but it should be borne in mind that the land was enriched by the cowpea vines and by the manure from the pigs.

To compare the value of ground cowpeas and corn with ground corn alone a further test was made with the same pigs. Lot 1 was continued on an exclusive corn ration and lot 2 was fed ground corn and ground cowpeas 1:1. The test covered 70 days and was preceded by a preliminary period of 7 days. Lot 1 gained 68 lbs., consuming 548.2 lbs. of corn, or 8.06 lbs. per pound of gain. Lot 2 gained 108 lbs., consuming

569.9 lbs. of corn meal and ground cowpeas, or 5.28 lbs. of the mixture per pound of gain. The nutritive ratio of the ration fed to lot 1 was 1:9.7 and of lot 2, 1:6.2.

It was planned to duplicate this test, comparing cowpea pasture with corn meal with 2 Essex sows with litters of 6 and 7 pigs, respectively. The test was discontinued after 3 weeks owing to the death of one of the sows. During this time the sow and 6 pigs fed corn in addition to cowpea pasturage gained 29.9 lbs., while the sow and 7 pigs fed corn alone lost 9 lbs.

Sweet potatoes vs. corn meal (pp. 126-129).—The 6 Poland-China pigs used in the first test recorded above were divided into 2 equal lots weighing 191.5 lbs. and 189.2 lbs., respectively. After a preliminary period of 1 week the test began November 4 and covered 2 periods of 28 days each. During the first period lot 1 was fed sweet potatoes and ground peas, 3:1, and lot 2 was fed corn meal and cowpeas 1:1. Both lots were given all they would eat. Owing to the different character of the rations it was not found possible to give them the same amount of dry matter. During the second period the rations were reversed. During the whole test the pigs fed sweet potatoes and cowpeas gained 65.8 lbs., consuming 877.7 lbs. of food, or 13.34 lbs. (equivalent to 6 lbs. dry matter) per pound of gain. The pigs fed corn meal and cowpeas gained 130.2 lbs., consuming 520.8 lbs. of food, or 4 lbs. (equivalent to 3.6 lbs. dry matter) per pound of gain. The author attributes the poor gains made on sweet potatoes to the fact that the pigs could not eat a sufficient amount of the bulky ration, and believes that more favorable returns would have been obtained with a ration of equal parts of sweet potatoes and cowpeas. It was calculated that the sweet potatoes returned only 13 cts. per bushel.

“This does not imply that sweet potatoes can not be profitably employed as food for hogs; but a profit is possible only by saving the expense of harvesting, the heaviest single item of expense in sweet-potato culture. If the hogs do the rooting, the sweet potato is doubtless a cheaper food than corn on some sandy soils that yield 10 to 15 times as many bushels of sweet potatoes as of corn. The vines are also valuable as food for hogs.

“The value of sweet potatoes will be enhanced by feeding with them a liberal allowance of cowpeas or peanuts, which supply the nitrogenous material in which the sweet potato is deficient.”

The pigs used in the various tests were slaughtered and the total dressed weight was recorded, as well as the ratio of the lungs, heart, liver, spleen, kidneys, etc., to the total weight.

The author discusses the effect of cowpeas and peanuts on the quality of pork. The average melting point of leaf and body lard from pigs fed corn meal and cowpeas was 45.3° C.; from pigs fed corn alone, 43.7°; from pigs fed peanuts and corn, 40.5°, and from pigs fed peanuts alone, 24.5°.

The author remarks that it is a common practice among farmers when pigs have been fed peanuts, sweet potatoes, and acorns to give them

corn alone for several weeks before slaughtering. This is done to harden the meat. With the view of obtaining information on this point, 1 pig each from the lots fed cowpeas and corn meal, peanuts alone, and peanuts and corn meal was fed corn only for a month before slaughtering. The melting point of the lard from the 3 pigs was 43°, 38.5°, and 37°, respectively. Cooking tests were made of the pork from the different pigs.

“Cowpeas fed with corn did not injuriously affect the quality of pork or lard. Peanuts when fed with corn greatly softened the pork and lard. The softening effect of peanuts was still greater when they constituted the sole food. This softening effect of peanuts was not corrected by feeding exclusively on corn for a month before the date of slaughtering. . . . Lard from exclusive peanut feeding solidified only during the coldest weather of February, at other times in February and March becoming almost a semiliquid. The low melting point or want of firmness of lard made from peanuts injures its sale. However, cooking tests fail to reveal any real inferiority.”

Some experiments with poultry, C. D. SMITH, C. S. BROOKS (*Michigan Sta. Bul. 158, pp. 329-341*).—The authors describe the station poultry house, discuss several trials with incubators, and report a number of feeding experiments with poultry. The chemical composition of eggs of different breeds and under different conditions of feeding is also given.

Coarsely cracked vs. finely ground grain for young chickens.—Eighty-six Barred Plymouth Rocks and 14 Golden Wyandotte chickens were divided into 2 equal lots 10 days after hatching. Lot 1 was fed coarsely cracked corn from which the meal was sifted and an equal weight of clean wheat screenings; lot 2 was fed corn and wheat in the same proportions, the grains being ground to a coarse flour. In addition both lots were given enough sweet skim milk to thoroughly moisten the grain, and the same amounts of oyster shells, finely cut green bone, lettuce, and cabbage.

At the beginning of the test, which lasted 7 weeks, lot 1 weighed 5.7 lbs. and lot 2 5.8 lbs. During the test 7 chickens in lot 1 and 6 in lot 2 died. At the close of the test lot 1 weighed 49.8 lbs. and had eaten 39.25 lbs. of wheat screenings and the same quantity of corn. Lot 2 weighed 59.5 lbs. and had consumed a pound more of each of the grains than lot 1. The conclusion is reached that there was a slight advantage in grinding the grain for young chickens.

Immediately after the close of this test a comparison of wheat and cracked corn was made with the same lots. The test was divided into 2 periods of 6 weeks each. Lot 1 was given whole wheat and lot 2 coarsely cracked corn, each lot being fed the same amounts of lettuce, cabbage, rhubarb, oyster shells, and green bone. In the first period lot 1 gained 51.7 lbs., consuming 2.8 lbs. of wheat per pound of gain. Lot 2 gained 117 lbs., consuming 2.77 lbs. of corn per pound of gain. During the second period lot 1 gained 72.5 lbs., consuming 2.62 lbs. of wheat per pound of gain, while lot 2 gained 83 lbs., consuming 2.5 lbs.

of corn per pound of gain. The amounts of lettuce, green bone, etc., consumed are recorded and were quite considerable.

In the author's opinion there was no great difference in the feeding value of the wheat and corn. "The gains made were satisfactory and again point to the advantage, if not the necessity, of variety in the ration of growing fowls."

The feeding of the 2 lots was continued to see if more food was required for a pound of gain as the chickens grew heavier. Both lots were fed oyster shells, green bone, sunflower seed, and turnip tops in addition to the grains. In 3 weeks lot 1 gained 21.8 lbs., consuming 6.56 lbs. of grain per pound of gain. Lot 2 gained 23.5, consuming 5.8 lbs. of corn per pound of gain. "These figures are significant and go far to show that one of the most common mistakes in poultry fattening is holding the chickens too long in the fall."

Relative gains of young ducks and chickens.—A lot of 39 ducks 2 weeks old at the beginning of the test was compared with an equal number of chickens of the same age in order to learn which could be more profitably fattened. The ducks were given middlings, corn meal, and bran, together with necessary grit and green food. They had the run of a small yard. The chickens were fed bran and relatively more corn meal than the ducks, but had no middlings. They were allowed the run of a small grass plat and were also given lettuce. At the beginning of the test the ducks weighed 13.25 lbs. and the chickens 7.5 lbs. In 5 weeks the ducks were nearly ready for the early market and had gained 108.75 lbs. They had eaten 41.3 lbs. of corn, 93.1 lbs. of middlings, 43.4 lbs. of bran, 59 lbs. of lettuce, and 88 lbs. of skim milk. The total cost of a pound of gain was 1.9 cts. In the same period the chickens had gained 30 lbs. and had consumed 52.2 lbs. of corn, 25.9 lbs. of bran, 46 lbs. of lettuce, and 44.3 lbs. of skim milk. The total cost of a pound of gain was 4.84 cts. The financial statement is based on corn and bran at \$14, and middlings at \$15 per ton, milk at 20 cents per hundred, and lettuce at 1 cent per pound. The ducks gained much more rapidly than the chickens and the gains were more economically made. The chickens were not large enough for market at the close of the test and the feeding was continued for some time before they were sold. The gains made and the cost of gain are briefly reported.

Feeding laying hens.—Three lots of hens, each made up of 4 Minorcas, 4 White Plymouth Rocks, 9 Barred Plymouth Rocks, 5 Light Brahmas, 8 grade Plymouth Rocks, and 5 crossbred Buff Wyandotte-Light Brahmas, were fed 6 months under the same conditions. Lot 1 laid 2,228 eggs; lot 2, 2,362, and lot 3, 2,288.

"While this difference is not large, had a change in condition, whether of feeding or some other item involved in the care been made between these pens, the difference would have been large enough to be considered somewhat significant. The fact that it occurred when all known conditions were alike teaches again the danger of drawing conclusions from the results of one experiment."

A comparison was also made with Golden Wyandottes, Single-Comb Brown Leghorns, and Barred Plymouth Rocks. The 3 lots received the same care and same rations. They were given a mixed diet containing as great a variety of food as possible, consisting of corn, oats, bran, wheat, and linseed meal. The test covered a year.

"The Wyandottes laid in the year 3,555 eggs, weighing 451.8 lbs.; the Leghorns laid 3,225 eggs, weighing 322.5 lbs., and the Plymouth Rocks 3,360, weighing 419.2 lbs. The hens were fed alike and consumed approximately the same quantity of food. The . . . record shows a marked difference of breeds in the number of eggs laid."

Winter feeding of capons.—A test to see whether feeding could be profitably carried on in winter was begun September 1 with 50 capons of a number of different breeds. During the test, which closed March 1, 9 capons died. The total food consumed was as follows: 743 lbs. corn, 236 lbs. table scraps, 120 lbs. wheat, 74 lbs. bran, 80 lbs. oats. The capons were worth at the beginning of the trial \$10.20; their average weight was 2.55 lbs. At the close of the test the average weight was 8.2 lbs. Rating corn at 70 cts., wheat at 65 cts., bran at 70 cts., and oats at 20 cts. per bushel, and table scraps at 2 cts. a pound, the total profit of feeding the capons was calculated to be \$5.22.

Chemical composition of eggs.—The chemical composition of eggs of a number of breeds was determined by L. A. Chittenden and reported by the authors. The eggs laid by the different breeds were found to have approximately the same composition. The effect of the character of the rations on the composition of eggs was also tested with two lots of Barred Plymouth Rocks, Wyandottes, and Brown Leghorn chickens. The test covered 6 weeks. Lot 1 was fed meat scraps, wheat, and linseed meal, 1:8:1. Lot 2 was fed corn, tallow, and rice meal, 7:1:2. Both lots were given lettuce and oyster shells in abundance. The composition of the eggs is reported in detail. No marked variation in the composition of the eggs due to different rations was observed, but the test is not regarded as conclusive, since it was of short duration.

On the composition and food value of native beans, BALLAND (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 15, pp. 532-534).—The maximum and minimum composition of French beans is reported.

Complete bread, A. CELLI (*Salute Pub.*, 11 (1898), No. 1, pp. 1-5).—A comparison of ordinary bread with that made by the "antispire" system.

The bread question, U. MILONE (*Reforma Chim.*, 1 (1897), pp. 419-429).—A discussion of the "antispire" system bread.

Wheat bread, TISON (*Jour. Hyg.*, 23 (1898), No. 1157, pp. 561-563).

Utilization of by-products of the dairy, H. E. ALVORD (*U. S. Dept. Agr. Yearbook 1897*, pp. 509-528).—The food value of skim milk, whey, and buttermilk is discussed. In addition to the value of these materials as food for animals, attention is called to their use for a number of manufactured products. The value of skim milk as a fertilizer is also noted.

The needs and requirements of a control of feeding stuffs, E. W. ALLEN (*U. S. Dept. Agr. Yearbook 1897*, pp. 421-428).—The variation in composition of concentrated feeding stuffs owing to changes in manufacture or adulteration is pointed out and

the need of State control similar to that of fertilizers is insisted upon. It is noted that in many cases inferior goods are sold under names which are delusive. So-called condimental feeding stuffs are also discussed. As shown by analysis, these materials have comparatively little feeding value as compared with their price. The medicinal substances which they contain are of doubtful value and, as shown by tests, they do not produce the improvement which is claimed for them.

Composition and nutritive value of millet, BALLAND (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 4, pp. 239, 240).—The maximum and minimum composition of African, French, Italian, and Turkish millet is reported.

On the quality of the so-called molasses feed, now found on the market, M. WEIBULL (*Tidskr. Landtmän*, 19 (1898), No. 24, pp. 413-426).—Ten samples of different origin were examined and analyzed, and only three samples were found of standard quality, made up of beet molasses, wheat bran, and palm-nut meal, in the proportions of 50:40:10.

Investigation of the milling products of rye which are used as feeding stuffs, B. SCHULZE (*Ztschr. Landw. Kammer Schlesien*, 1898; *abs. in Centbl. Agr. Chem.*, 27 (1898), No. 11, pp. 746-751).—A report of the examination of a large number of samples of rye bran, etc. The various causes which injure such feeding stuffs are pointed out.

Nutritive value of mushrooms, MARY H. ABEL (*Amer. Kitchen Mag.*, 9 (1898), No. 4, pp. 127, 128).—A general discussion of the subject. The author calls attention to the fact that the actual amount of nutriment in mushrooms is small.

Chicory: Its manufacture, sophistication, and adulteration, A. RUFFIN (*Bul. Assoc. Chim. Sacr. et Distill., France*, 16 (1898), No. 1, p. 107).—A note on a paper presented before the Société Chimique du Nord de la France, and also the Société industrielle du Nord de la France.

Preservation of eggs (*Jour. Soc. Arts*, 46 (1898), No. 2363, p. 370; *abs. in Jour. Soc. Chem. Ind.*, 17 (1898), No. 3, pp. 261, 262).—A brief account of experiments previously noted from another source (*E. S. R.*, 9, p. 981).

Foods, A. P. BRUBAKER (*Sci. Amer. Sup.*, 46 (1898), No. 1196, pp. 19179-19182).—A lecture delivered at the Drexel Institute, Philadelphia, and revised by the author for publication.

Food and feeding, SIR H. THOMPSON (*London: F. Warne & Co., 1898, 9 ed. rev. and enl.*, pp. 312).

The feeding of farm animals (*Rpt. Agr. New Brunswick*, 1897, pp. 183-208).—This is a reprint of U. S. Dept. Agr., Farmers' Bulletin 22.

The principles of stock feeding, W. J. SPILLMAN (*Washington Sta. Bul.*, 29, pp. 31).—A general treatise on the subject. Among the points covered are the composition of the animal body, uses of foods, constituents of feeding stuffs and the functions of each, compounding rations, feeding standards, and rearing calves. The amount of digestible nutrients in a number of feeding stuffs are shown and a number of feeding standards for various farm animals are quoted. Some of the points are discussed with special reference to conditions prevailing in the State.

Contributions to the comparative physiology of digestion. II, An enzyme in the liver secretion of Helix pomatice which dissolves cellulose, W. BIEDERMANN and P. MORITZ (*Arch. Physiol. [Pflüger]*, 73 (1898), No. 5-6, pp. 219-287).

Increase in body weight by transformation of fat into glycogen, C. BOUCHARD (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 14, pp. 464-469).—Experiments are reported in which a rabbit, a mouse, and dogs were fed fat. The conclusion was reached that under certain conditions sugar can be formed from fat.

Observations on the supposed transformation of fat into glycogen, M. BERTHELOT (*Compt. Rend. Acad. Sci. Paris*, 127 (1898), No. 15, pp. 491-496).—A discussion of the question of the formation of sugar from fat proposed by C. Bouchard. (See above.)

History of cattle and their rôle in civilization, CHESTER (*Histoire et rôle du bœuf dans la civilisation*. Paris: Schleicher Frères, 1898).—This is a volume of *Livres d'Or de la Science*: rev. in *Jour. Hyg.*, 23 (1898), No. 1154, pp. 517-521.

Studies of Bos (brachyceros) europæus, the wild form from which the domestic cattle of Europe are descended, L. ADAMETZ (*Jour. Landw.*, 46 (1898), No. 3, pp. 269-320, pls. 2).

Some deductions drawn from the weight of slaughtered cattle, P. FALK (*Ztschr. Fleisch u. Milchhyg.*, 8 (1898), No. 10, pp. 183-187).—The weight of the contents of the intestinal tract and of the blood and organs is reported in a number of cases.

Pork production, F. D. COBURN (*Kansas State Bd. Agr. Quart. Rpt. 1898, Sept.*, pp. 227, figs. 39).—Raising pigs in Kansas is discussed at considerable length. Many papers on raising pigs, pig feeding, diseases of pigs, and other general topics are quoted.

Eggs and poultry (*Rpt. Com. Agr. and Dairying Canada, 1897, pt. 8, pp. 33, figs. 12*).—Among other topics the number of eggs imported into Great Britain, the prices received, preservation of eggs, packing eggs, the value of poultry imported by Great Britain, and fattening of turkeys are discussed. Articles on eggs in winter and choice poultry, by A. G. Gilbert, are quoted.

Determining the age of poultry and game, W. NIEBEL (*Ztschr. Fleisch u. Milchhyg.*, 9 (1898), No. 2, pp. 21-27, figs. 7).—The methods discussed include difference in the wing feathers, spurs, etc., of birds of different ages.

A manual of hygiene and sanitation, S. EGBERT (*Philadelphia & New York: Lea Bros. & Co., 1898*: rev. in *Amer. Kitchen Mag.*, 10 (1898), No. 3, p. 112).

Abstract of a description of a respiration calorimeter furnished by Professors Atwater and Rosa, C. F. LANGWORTHY (*Jour. Amer. Chem. Soc.*, 20 (1898), No. 9, pp. 681-687).—A brief description of this apparatus (*E. S. R.*, 9, p. 863), with the results of a number of tests of its accuracy.

Dairy and food commission, J. E. BLACKBURN (*Ohio State Dairy and Food Com. Bul. 3, pp. 13*).—In addition to brief statements concerning adulterated butter, poisonous butter color, new vinegar law, and oleomargarine, and certain drugs and medicines, the bulletin contains an account of the proceedings instituted in Ohio against the manufacture of a well-known proprietary medicine. Brief statements are also made concerning samples procured in a number of cities for inspection.

Twelfth Annual Report of the Ohio Dairy and Food Commissioner (*Ohio State Dairy and Food Com. Rpt. 1898, pp. 232*).—Statements are made concerning the samples of oleomargarine, whisky, sugar, patent medicines, tea, baking powder, tainted meats, flavoring extracts, flour, candy, cheese, and vinegar examined, and court decisions are quoted. The report of the State Dairy and Food Commission chemists on a number of foods and drugs analyzed is given in detail, cases of the violation of law prosecuted are cited, and the expenditures in prosecuting the same.

DAIRY FARMING—DAIRYING.

Feeding experiments with cows at the experiment farm at Lauchstädt, F. ALBERT and M. MAERCKER (*Landw. Jahrb.*, 27 (1898), No. 1-2, pp. 188-203).—The object of this experiment was to study the effect on milk production of increasing the fat in the ration. Ten new milch cows were used, 5 Simmenthaler and 5 Altmärker. The experiment began early in February and lasted until the middle of June. The plan was to feed all of the cows alike, giving a constant basal ration of sugar beets, hay, and straw. To this was added in the preparatory period rape-seed cake, cotton-seed meal, and wheat bran, giving a total of 3 kg. of protein per 1,000 kg. live weight. The fat

content of the coarse fodder was left out of account, as this was constant in all the periods. It was 0.5 kg. in the preparatory period. In subsequent periods palm-nut cake and two kinds of cocoanut cake were substituted for a portion of the grain ration, so as to maintain the protein content exactly the same as in the preparatory period, and to increase the fat content of the ration up to 1.706 kg. per 1,000 kg. live weight. In the second and the last periods disemitted lupine was fed with the basal ration of coarse fodder and wheat bran, giving a ration relatively poor in fat. The changes from one ration to another were made gradually and were not accompanied by any apparent disturbance of the cows.

A summary of the average results with each cow is given in the following table:

Effect on milk of feeding rations rich and poor in fat.

Cow No.	Preparatory periods.						Ration rich in fat, I.			Ration poor in fat.		
	Averages from Feb. 10-12.			Normal ration; 0.504 kg. fat. Averages from Feb. 15-21.			Palm-nut cake; 0.937 kg. fat. Av. March 1-7.			Disemitted lupine; 0.297 kg. fat. Av. March 20-30.

Cows 655 to 3579 were of the Simmenthaler breed and 1 to 5 of the Altmärker.

The authors conclude that a one-sided increase of the fat content of the ration up to 1 kg. of fat per 1,000 kg. live weight had no influence

on the yield of milk, but that with a ration of 1.706 kg. of fat per 1,000 kg. live weight there was a marked decrease in the milk yield.

The effect of palm-nut cake and cocoanut cake in increasing the fat content of the milk the author regards as beyond question. As compared with the normal ration fed in the preparatory period, there was an increase in the fat content of the milk of 0.31 per cent with palm-nut cake, 0.28 per cent on the first cocoanut-cake ration, and 0.75 per cent on the second cocoanut-cake ration which was unusually rich in fat.

In regard to the total yield of butter fat, the conclusion is reached that "the increase of the fat content of the milk which can be brought about at will by feeding rations rich in fat is almost without effect on the total amount of fat, and may result in a financial loss. . . The use of large amounts of expensive feeding stuffs rich in fat should be avoided, since the possibility of a one-sided increase of the fat content of the milk may lead to a positive loss."

A consideration of the fluctuations in live weight shows that the 1 lb. of fat eaten daily by the cows on the ration richest in fat was not lost but was used for the production of body fat. The Simmenthaler cows were more sensitive to the fat in the ration than the others, as shown by the fact that they decreased 10 kg. per head in weight when palm-nut cake was replaced by disemulsified lupine, while the Altmärker lost only 4 kg. In the first cocoanut-cake period the Simmenthaler gained 13.5 kg. and the Altmärker 11.1 kg. each; and during the second cocoanut-cake period, on the ration richest in fat, the Simmenthaler gained 19.4 kg. and the Altmärker 23 kg. each. The feeding left the Simmenthaler cows overfat and unfit for anything except butchering. The author believes the results suggest a possible means for rapidly fattening dry cows.

Experiments on the question whether in feeding sesame cake there is a transmission of material to the butter which gives the Baudouin reaction, H. WEIGMANN (*Milch Ztg.*, 27 (1898), No. 34, pp. 529-532).—[This much discussed question arises out of the regulation of the German oleomargarine law, passed in 1897, which requires the addition of sesame oil to all oleomargarine, as a means of identifying it. This is spoken of as the "latent coloring" of margarine; and the finding of the sesame-oil reaction in butter is taken as evidence that it has been adulterated with margarine.]

An experiment was made with several cows in which a part of the grain ration of some of the cows was replaced by 3 kg. per head of sesame cake, an amount said to be three times as great as is commonly fed in practice. The milk from the sesame-cake feeding was creamed and churned separately and the butter tested for the characteristic rose color with furfural and hydrochloric acid. None of the samples of butter from the sesame-cake feeding gave a reaction immediately on mixing with hydrochloric acid and furfural, and therefore it is considered that none of the samples of butter gave the sesame-oil reaction. These samples and also samples of butter produced without sesame-cake

feeding gave the reaction after a time (about 30 minutes) under certain conditions of temperature, strength of reagents, etc. This delayed reaction is believed to be due to a decomposition of the furfurol, as the reaction appeared sooner when large quantities of furfurol were present and when the butter was heated with the reagent. This was also borne out by experiments made with hydrochloric acid alone.

These facts in regard to the reaction explain, the author believes, the finding of sesame-oil reaction in butter by other investigators when sesame cake was fed. Providing the reaction is made according to the prescribed method of the Imperial Health Office, the experiments indicate that no reaction due to the sesame-cake feeding will be found.

The sesame-oil reaction in natural butter, VIETH (*Milch Ztg.*, 27 (1898), No. 36, pp. 563, 564).—The author cites a number of instances, among others, some in his own laboratory, in which natural butter from cows which had been fed sesame cake gave the sesame-oil reaction. He considers, for this reason, that the determination of the adulteration of butter with margarin by the "latent coloring" of the latter with sesame oil can not be regarded as an easy and reliable means.

Experiments on the effect on milk production of feeding sugar beets and dried and ensiled diffusion residue, O. KELLNER and G. ANDRÄ (*Landw. Vers. Stat.*, 49 (1898), No. 6, pp. 402-418).—This experiment was made with 24 cows on a private estate, but was under the immediate supervision of the Mückern Station. The time of the experiment was divided into 4 periods of 20 days each, the first 8 days of each period being regarded as preparatory. The cows were all fed alike, receiving the same basal ration throughout and practically the same amounts of digestible nutrients in the different periods. The basal ration consisted of hay, straw, linseed meal, cotton-seed meal, peanut meal, and wheat bran, to which was added, per 1,000 kg. live weight, 50 kg. of sugar beets in the first and fourth periods, 8 kg. of dried diffusion residue from a sugar-beet factory in the second period, and 76 kg. of ensiled diffusion residue in the third period. The silo used was merely a hole in the ground, not walled up or plastered; the loss was 33 per cent in weight.

The cows were milked three times daily and the weight of milk, specific gravity, and fat content (the latter by the Gerber method) were determined. The total solids were calculated by Fleischmann's formula. The results are given below:

Results of feeding sugar beets and diffusion residue to cows.

Period.		Average milk yield per day.	Total solids.	Fat content.
		<i>Kg.</i>	<i>Per cent.</i>	<i>Per cent.</i>
1.....	Sugar beets.....	13.755	12.87	3.51
2.....	Dried diffusion residue.....	14.101	12.88	3.60
3.....	Ensiled diffusion residue.....	14.348	12.72	3.45
4.....	Sugar beets.....	12.107	12.92	3.45

The tables of composition do not indicate that the different rations had any noticeable effect on the composition of the milk. The conclusion is reached that both the dried and the ensiled diffusion residue were more favorable to milk production than sugar beets. Making allowance for the natural shrinkage in the yield, on the basis of the first and fourth periods, it is stated that as a result of the substitution of 4.4 kg. of dried diffusion residue in place of 27.5 kg. of sugar beets the milk yield increased 0.953 kg., and of substituting 41.8 kg. of ensiled diffusion residue for the above amount of beets it increased 1.721 kg. per cow (of 550 kg. live weight) without any particular change in the quality of the milk. In the second and third periods when diffusion residue was fed there was in general an increase in the live weight as compared with the first and fourth.

Experiments on the effect on milk production of some new feeding stuffs, with special reference to the fat content, E. RAMM and W. MINTROP (*Milch Ztg.*, 27 (1898), No. 33, pp. 513-519).—The object of this experiment was not only to compare certain new feeding stuffs, as cocoa-molasses, molasses-distillery-refuse, blood-molasses, and corn bran, but also to study the effect on the yield and composition of milk of rations furnishing different amounts of fat and protein. The cocoa-molasses was prepared by mixing hot molasses with finely ground cocoa shells. The molasses-distillery-refuse was the residue from the manufacture of alcohol from beet molasses. The blood-molasses was a mixture of blood, molasses, and refuse of cereals.

The experiment began November 5, 1897, and closed May 8, 1898, the time being divided into 10 periods of unequal duration, and the last 5 days of each period being considered. Five cows were used, but owing to the condition of the cows, as subsequently developed, 2 had to be discarded in making up the averages. A basal ration of hay, cut straw, and sugar beets was fed throughout. The rations fed per 1,000 kg. live weight and the yield and fat content of the milk are shown in the following table:

Effect of different rations on milk production.

Period.	Food in addition to basal ration, per 1,000 kg. live weight.	Digestible nutrients in food.			Average daily yield of milk per cow.	Average fat content of milk.	Average yield of fat per 1,000 kg. live weight.
		Protein.	Fat.	Nitrogen-free extract.			
		<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Kg.</i>	<i>Per ct.</i>	<i>Kg.</i>
1.....	12 kg. malt sprouts.....	2.266	0.427	14.539	15.317	2.957	0.8176
2.....	12 kg. cocoa-molasses.....	1.414	.637	13.723	10.244	3.873	.6993
3.....	8 kg. cocoa-molasses and 3 kg. peanut cake ..	2.486	.719	13.068	12.748	3.437	.7809
4.....	8 kg. linseed cake ..	5.557	1.126	11.861	12.979	2.990	.7036
5.....	8 kg. malt sprouts and 3 kg. linseed cake..	2.443	.693	13.710	12.805	2.880	.6652
6.....	8 kg. malt sprouts, 3 kg. linseed cake, and 2 kg. molasses-distillery-refuse.....	2.603	.706	14.104	11.828	2.790	.5929
7.....	12 kg. corn bran.....	2.012	.658	15.260	12.162	2.327	.5013
8.....	8 kg. corn bran and 3 kg. linseed cake ..	2.275	.847	14.808	12.262	2.74	.5979
9.....	8 kg. corn bran and 7 kg. blood-molasses ..	2.121	.603	16.451	13.089	2.990	.6939
10.....	12 kg. malt sprouts.....	2.266	.427	14.554	10.546	3.110	.5824

The yield of milk fell off one-third in the second period on cocca-molasses, believed to be due to the deficiency in protein. The addition of peanut cake in the following period resulted in an increase in yield. The corn bran had a favorable effect on the yield. The fat content of the milk showed wide fluctuations in different periods. Molasses is believed to have had a favorable effect on the fat content wherever it was fed, while the corn bran tended to reduce the fat content. As to the effect of the rations rich in fat, it is believed that there was no apparent relation between the high fat content of the ration and the fat content of the milk. On the two rations rich in fat (periods 4 and 8) the fat content of the milk was below the average, while on the ration poorest in fat (periods 1 and 10) the fat content was above the average. The rations containing corn bran gave the largest production of solids-not-fat. The malt sprouts and linseed cake gave an increase in live weight when they were fed alone or when fed in combination with other feeds. There was a small decrease in live weight on the molasses rations.

In conclusion, the authors state that in agreement with previous results a high fat content of a ration by no means resulted in the production of milk of a high fat content. It is believed, therefore, that little attention need to be paid to the fat content of the ration beyond providing a certain minimum amount—i. e., 0.4 to 0.7 kg. per 1,000 kg. live weight, and that the nitrogen-free nutrients required in excess of this can be more cheaply supplied in the form of carbohydrates.

The different feeding stuffs are considered to have brought about unusually large differences in the percentage of fat in the milk. Excluding the second ration, which was low in fat, the fat content of the milk on normal rations ranged from 2.327 (period 7) to 3.437 per cent (period 3), a difference of 1.11 per cent. This, it is believed, can not be attributed to the slight differences in the composition of the ration, but supports the theory that different feeding stuffs have a specific action sufficiently strong to affect the value of a ration. In determining the value of a feeding stuff, not only the proportion of nutrients must be considered, but also the specific action of the material, and this can be determined only by direct experiment, at least until we understand the principle on which this specific action rests.

As to the relative value of the new feeding stuffs tested, the cocca-molasses proved to be a good and cheap concentrated feed for cows; the molasses-distillery-waste in the form in which it was used gave a negative result; the corn bran was eaten readily by the cows in large quantity without ill effect, and as it appeared to have a favorable effect on milk secretion it can be recommended; and the blood-molasses is to be regarded as a most valuable concentrated feed.

The comparative value of buckwheat middlings, dried brewers' grains, and Cerealine for milk and butter production, II. HAYWARD and R. J. WELD (*Pennsylvania Sta. Bul. 41, pp. 18, dgm. 1*).—The experiment was with 12 cows and covered 3 periods of 40 days

each. A constant basal ration of 3 lbs. corn meal, 1 lb. linseed meal, about 9 lbs. hay, and corn stover *ad libitum* was fed throughout. During the first and third periods all the cows were fed 4 lbs. buckwheat middlings per head in addition to the basal ration. During the second period 4 cows were fed the same ration as in the first and third periods, 4 were fed 1 lbs. brewers' grains, and 4 others 4 lbs. Cerealine, in place of the buckwheat middlings. Summaries of the rations actually eaten, the computed digestible matter of the rations, and the yield of milk are presented in tabular form, and a diagram is given representing the amount of fat produced by each cow throughout the experiment. Following are the conclusions reached:

"(1) The results of this experiment indicate that, for milk and butter production, dried brewers' grains, buckwheat middlings, and Cerealine are equally valuable when fed judiciously, as part of a balanced ration.

"(2) So far as could be observed, none of these foods produced a detrimental effect upon the flavor or quality of the milk and butter.

"(3) In view of the results stated, the choice of the above-mentioned foods would depend entirely upon their cost delivered at the railroad station.

"(4) With prevailing prices for dairy products and food stuffs, and with good cows, milk and butter can be produced at such a cost as to leave a considerable margin of profit for the dairyman."

Tests of dairy methods and apparatus, J. W. HART (*South Carolina Sta. Bul. 33, pp. 13*).—The feeding and care of cows, the testing of milk, and making of butter, and other topics connected with dairying are discussed in a general way. Pasteurized milk was treated with Hansen's lactic ferment, but it was considered that this failed to improve the flavor of the butter. It was believed that better results were obtained by using a fermentation starter from skim milk than by using sour buttermilk, sour cream, or leaving the ripening to the action of the germs adventitiously present. Experiments were conducted to compare different methods of making butter and to test different cream separators. Churnings were made of whole milk and of cream obtained by deep setting and by the use of four different separators. Of 17 churnings of whole milk the buttermilk contained on the average 1.5 per cent of fat, a loss of 30 per cent of the fat contained in the milk. The skim milk from 5 deep settings showed an average fat content of 0.98 per cent. It was thought that there was no difference in the churnability of the cream from the various separators. In hot weather the use of ice in churning increased the quantity and improved the quality of the butter. Cream showing an acidity of 0.7 per cent by Farrington's alkaline tablets yielded the most butter. In one experiment the the same quantity of milk, about 4 gal., was put in each of 2 churns, one having a capacity of 10 and the other 60 gal., the other conditions being as nearly identical as possible. Over 7 per cent more finished butter was obtained from the larger churn, hence the author concludes that a churn should not be filled over one-third full. "The separator butter was usually scored higher than that made from whole milk, but

the difference was slight." Of the 5 separators used the best results were obtained from the Alpha De Laval Humming Bird Separator, which left only 0.084 per cent of fat in the skim milk as an average of 3 tests. No difference was observed in separating the cream immediately after milking or after a period of 12 hours, but better results were obtained by heating the milk to 160° before separating.

Gravity or dilution separators, H. H. WING (*New York Cornell Sta. Bul.* 151, pp. 35-47, fig. 1).—Reference is made to work on cream raising by dilution reported in Bulletin 39 of the station (E. S. R., 4, p. 361). Descriptions are given of Wheeler's Gravity Cream Separator, Hunt's Improved Ventilated Cream Separator, and the Aquatic Cream Separator, with the claims of the manufacturers. The first two "separators" are considered similar in all essential features to the Cooley, Moseley, and other cans used in deep setting; the Aquatic differs in being provided with another smaller can intended to be filled with ice and inserted in the large can as a cooler. Fifteen tests were made of the Wheeler and Hunt cans in comparison with Cooley cans, and 5 of the Aquatic. Tests of other cans were also made at various farms. The data obtained are tabulated and discussed. The following conclusions were reached:

"Gravity or dilution separators are merely tin cans in which the separation of cream by gravity process is claimed to be aided by dilution with water. Under ordinary conditions the dilution is of no benefit. It may be of some use when the milk is all from 'stripper' cows, or when the temperature of melting ice can not be secured. These cans are not separators in the universally accepted sense of that term, and can not rank in efficiency with them. They are even less efficient than the best forms of deep-setting systems, such as the Cooley Creamer. They are no more efficient than the old-fashioned shallow pan, but perhaps require rather less labor. In all probability they would give better results if used without dilution and immersed in as cold water as possible, preferably ice water."

The relation of certain bacteria to the production of butter, C. H. ECKLES (*Centbl. Bakt. u. Par.*, 2. Abt., 4 (1898), No. 19, pp. 730-734; 20, pp. 759-763).—Experiments are reported with the use of 4 species of bacteria in butter making, viz, *Bacillus subtilis*, *B. vulgatus*, No. 13 obtained from milk from the Iowa Agricultural College creamery, and *B. lactici-acidi*. The effects of the first two were bad, producing "butter of no market value. It is a significant fact that these are species closely connected with dirt and filth." The other two, both belonging to the lactic acid group, produced butter of fine quality, with an unusually pleasant aroma.

"The full effect of *B. subtilis* and *B. mesentericus vulgatus* is not reached until from 3 to 5 days after manufacture. This shows that an examination made at once after churning is misleading. No. 13, which produces such a marked and pleasant aroma when grown in milk, gives much less aroma to butter than does No. 8, which has but slight aroma in milk."

The rôle of lactic-acid bacteria in cheese ripening, H. WEIGMANN (*Centbl. Bakt. u. Par., 2. Abt., 1 (1898), No. 15-16, pp. 593-607; 17-18, pp. 669-674; and Milch Ztg., 27 (1898), No. 42, pp. 660-663; 43, pp. 673-675; 45, pp. 706, 707*).—This is an extended discussion of the part played by lactic-acid bacteria in cheese ripening, with special reference to von Freudenreich's work. The author concludes from his review of the subject and from his own work that—

(1) The specific lactic-acid bacteria are not cheese-ripening bacteria, the form used by von Freudenreich in his experiments being only facultative or more probably degenerate lactic acid bacteria.

(2) Lactic-acid bacteria have an important rôle in cheese ripening, not in actually taking part in the ripening, but by directing the process in the right direction.

(3) This function consists in eliminating certain forms of bacteria and fungi by the lactic acid formed, and providing an acid nutrient medium upon which only such bacteria and fungi can thrive as can withstand the acid or consume it. The micro-organisms which consume the acid prevent its accumulation in too strong a degree, take part in the peptonizing and flavor-producing processes, and enable other bacteria or fungi whose activity was weakened by the acid to continue their work.

(4) The specific character of a particular kind of cheese depends upon the predominating form of micro-organism which the manner of preparation and the handling of the cheese have brought about.

Preliminary report of tests of the Thistle milking machine, B. MARTINY (*Mitt. Deut. Landw. Gesell., 13 (1898), No. 18, pp. 281-285; and Milch Ztg., 27 (1898), No. 42, pp. 657-660*).—Two tests of 77 and 10 days, respectively, were made on a private estate, 10 of the heaviest milkers being selected from a herd of 120 Dutch cows. In each test the cows were milked in alternate periods by hand and with the machine. The results as to yield and fat content of the milk are fully tabulated for the individual cows. The machine was found satisfactory and did not cause any disturbance or shrinkage of the cows. There is believed to be greater difficulty in keeping impurities out of the milk, especially micro-organisms, than with hand milking, and it is recommended to pasteurize machine-drawn milk immediately after milking. It is questioned whether in the case of young cows machine milking will make as good milkers as hand milking. As the machine is complicated and requires to be carefully looked after, the author doubts whether it simplifies or lightens the management of a dairy farm, provided good hand milkers can be procured.

Passburg's dry milk (Trockenmilch), G. BAUMERT (*Ztschr. Angew. Chem., 1898, No. 13, pp. 297, 298*).—Analyses are given of this product made by evaporating milk at a low temperature without the addition of any foreign material, and of tablets made from it by mixing with it a little cocoa, sugar, etc. The product is said to keep well.

Preparation of casein from skim milk (*Chem. Ztg., 22 (1898), No. 87, p. 930*).—Three patents have been granted in England to H. Higgins for the preparation of casein from skim milk by means of hydrochloric acid, in the proportion of 5 lbs. of acid to 100 gal. of hot skim milk (130 to 140° F.); and the manufacture of several dried food products from it, either alone or mixed with flour, rice, tapioca, sugar, aromatic substances, etc.

Comparative tests of butter fat, F. S. SHIVER (*South Carolina Sta. Bul.* 33, pp. 13, 14).—A comparison of the Babcock test and the Adam's gravimetric method on whole milk, skim milk, and buttermilk. "The Babcock method with the machine used gives very satisfactory results as compared with the gravimetric method." The average percentages of fat by the two methods were as follows:

Fat content by Babcock and gravimetric analysis.

	No. of comparisons.	Gravimetric.		Babcock.		Difference.	
		Per cent.	Per cent.	Per cent.	Per cent.		
Whole milk.....	49	4.77	4.83	4.83	0.06		
Skim milk by deep setting.....	5	1.05	1.15	1.15	.10		
Buttermilk.....	4	1.50	1.58	1.58	.08		

"These differences between the two methods are within the limit of error between duplicate determinations by the gravimetric method in current work."

Correction of the reading of the Babcock test for cream, W. J. SPILLMAN (*Washington Sta. Bul.* 32, pp. 3-5).—It is pointed out that while the 17.6 cc. pipette used in the Babcock test delivers 18 gm. of milk, with cream "the pipette fails to deliver 18 gm. because cream is so much lighter than milk; hence the test reads considerably lower than it should, and the richer the cream the greater the error." The author proposes to overcome this by correcting the reading by a table, which he gives for this purpose. The table gives the correction to be made and the corrected reading for cream containing from 10 to over 70 per cent of fat. The method by which the table is calculated and its use in practice are explained.

Effect of richness of cream on acid test, W. J. SPILLMAN (*Washington Sta. Bul.* 32, pp. 5-7).—The failure to obtain uniform results with cream ripened to the same degree of acidity but differing in richness is explained on the ground that "the acid of the cream is all contained in that part of the cream that would remain if the fat were all removed, i. e., in the serum," and that accordingly "bacterial action has progressed twice as far in 60 per cent cream as in 20 per cent cream when they show the same degree of acidity by the test." A table is given showing the actual degree of acidity of cream of different richness as compared with 25 per cent cream testing 6 degrees of acidity. The practical use of the table in butter making is explained.

Testing of cream with Dr. Gerber's acid-butyrometry, M. KÄMRITZ (*Milch Ztg.*, 27 (1898), No. 44, pp. 694, 695).—A description of the method of testing cream with comparison with the gravimetric determination.

Use of pure cultures in butter making, F. S. COOLEY (*Massachusetts State Bd. Agr. Rpt.* 1896, pp. 169-176).—A popular address on dairy bacteriology, in which is mentioned a single comparative test of Conn's Bacillus 41, natural ripening, and a bacillus isolated at the Massachusetts Dairy School at Amherst. The results showed only slight differences in the flavor of the butter.

The practical side of dairy bacteriology, J. P. SHELDON (*Dairy*, 10 (1898), No. 118, pp. 279, 280).—A popular article.

Report of Swedish butter exhibitions for the year 1897, N. ENGSTRÖM (*Meddel. K. Landtbr. Styv.*, 1898, No. 44, pp. 44).

Colored spots in cheese, R. A. PEARSON (*U. S. Dept. Agr., Bureau of Animal Industry Circ.* 24, pp. 6).—A description based upon reports received at the office of cheese rust or colored spots of cheese, with evidence of the bacterial cause of the affection and a discussion of remedial and preventive measures. "So far as is known, these spots do not have any effect on the consumer." The destruction of the objectionable germs by the thorough cleaning and disinfection of factories is considered the only perfect remedy.

The spread of typhoid fever by milk, RAPMUND (*Ztschr. Medicinalbeamte*, 1897, No. 15; *abs. in Hyg. Rundschau* 8 (1898), No. 7, pp. 351-353).

The dairy interests of the United States, H. E. ALVORD (*Massachusetts State Bd. Agr. Rpt. 1896*, pp. 136-164).—An address delivered before a public meeting of the State Board of Agriculture reviewing the growth of the dairy interests of the United States during the last seventeen years and considering some of the reforms and improvements desirable or essential to future welfare.

Dairying in Denmark during 1897, B. BÖGGILD (*Tidskr. Landök., 17 (1898), No. 1-2*, pp. 56-87).

Report of the dairy agency in Manchester to the Swedish Agricultural Department for 1897, H. WEDIN (*Meddel. K. Landthbr. Styrel., 1898, No. 47*, pp. 71).

VETERINARY SCIENCE AND PRACTICE.

The lung and stomach worms of sheep, J. E. WING (*Ohio Sta. Bul. 91*, pp. 163-178).—In the introduction, which is by C. E. Thorne, it is stated that a disease caused by parasites in the lungs and known as "paper skin" or "white skin" has prevailed among sheep for an indefinite period, affecting lambs and yearlings chiefly. Citations are given from several papers.

The author describes the lung parasites: White threadworm (*Strongylus filaria*), the red threadworm (*S. rufescens*), and the hair worm (*Pseudalius oris*); and the stomach worm (*Strongylus contortus*). The fact is recognized that there is no certain cure for lung disease. The practice of smoking or fumigating lambs for lungworms is regarded by some with considerable favor. The more promising treatment, according to the author, consists of injecting into the windpipe a mixture of 2 parts olive oil and 1 part turpentine. From 1 to 3 teaspoonfuls is sufficient for a dose. A hypodermic syringe may be used for injecting. The experience of the author is quoted to show that if an intermediate host is necessary for the development of the lungworm, the period passed in the intermediate state is not necessarily very long. A number of strong, healthy ewes and large young lambs were put on a high rolling blue grass pasture of 40 acres. No sheep had been on this pasture the preceding year and, so far as known, sheep infested with parasites had never been pastured there. The grass was very luxuriant and the grazing was largely confined to a slope near a spring. The ground was thickly strewn with droppings and probably became infected from the sheep's nostrils as well. The sheep drank from the stream flowing from the spring. After a time some of the older lambs died quite suddenly. During June and July a number of lambs were born on the pasture and they seemed to thrive at first, but in about 45 days showed symptoms indicating the presence of the lungworm and, though treated with the usual remedies, they died. The older lambs were removed from the pasture and continued to thrive and the ewes remained healthy. In the author's opinion the young lambs obtained the parasites from the short grass and possibly from the water in the stream. "It is evident that older sheep in seeming perfect health may infect lambs with lungworm (and doubtless stomach worm) to a fatal extent, and this during a single season."

The stomach worm is described at length. The symptoms caused by its presence vary considerably. "There is disarrangement of the digestion, which may cause either scouring or constipation. Frequently the constipation succeeds the scouring. The lambs have abnormal appetites, eating irregularly, sometimes very little, then unusual amounts. They often eat rotten wood, earth, etc., and in fact this is the most characteristic symptom. The skin becomes pale, the strength declines, the flesh disappears, the wool is sunken and lusterless. For some reason there seems a greater mortality among ram lambs than among ewe lambs. Few lambs that reach the stage of emaciation ever recover or are of any value if they do recover. In some cases death is quite sudden, in others the lamb lingers for weeks or months."

One of the most common remedies for stomach worm is 1 part turpentine to 16 of milk, given in doses of 1 to 3 oz., according to the size and age of the lamb. The author does not regard this remedy as at all certain. "Seemingly good results, in truth the best results ever observed in practice have been obtained by using the following mixture: Pine tar, 8 parts; raw linseed oil, 8 parts; turpentine, 1 part. The dose is from 1 to 3 oz." The fact is pointed out that measures which prevent infection are much more promising than internal remedies. The lambs should be kept as much as possible from contaminated food or drinking water.

"It must be constantly borne in mind that these parasites are present in nearly or quite all flocks, even in times of health. The older sheep may not suffer perceptibly from the presence of the small number of strongyls, yet they are constantly passing the eggs with their excrement and thus polluting the herbage for how long a time we do not know—for at least one year we are certain. If sheep have fresh pasture each year there is not the same opportunity for the young worms to find entrance into the lambs, and thus the number will constantly decrease from year to year.

"If, on the other hand, sheep are made to feed over their own droppings from year to year, the worms will increase rapidly in numbers and will sooner or later become sufficient in number to nearly destroy the lamb crop.
